varieties of phosphate rock, using the Appiani method of levigation to sep. the crushed mineral into 4 fractions, according to the rate of fall through water, *i. e.*, 0.2, 2, 7, 25 mm. per sec. He found that the hard or nodulous varieties (Land Pebble, Angaur) differ from the friable varieties (Gapa, Constantine) in that they give a meal of greater fineness the higher their degree of hardness. The character of the granules of the several varieties also differs. Under the microscope, granules of friable phosphate rock are rounder or with truncated angles, while granules of the hard varieties present sharply angular or flattened forms. The fineness of the meal favors rapid procedure of the reaction of formation, or at least a more complete solubilization of the  $P_2O_5$ . Present modes of treatment should not allow over 10–12%  $H_2O$ , nor over 1–2% of free  $H_3PO_4$ , expressed as  $P_2O_5$ , corresponding to about 0.05–0.1 of the total sol.  $P_2O_5$ . The existence of  $CaHPO_4$  is a sure guaranty of the normality of constitution of the product. Normally constituted superphosphate has excellent physicommechanical properties, *i. e.*, dryness, pulverulency, abs. absence of pastiness. Abnormally constituted superphosphate has the following characteristics: (1) content in  $H_2O$  of the liquid phase above 12%; (2) free  $H_3PO_4$  exceeding the limit of 2% on the wt. of the product, or expressed in  $P_2O_5$ , in excess of 0.1 of the sol.  $P_2O_5$ ; (3) limited amount or absence of  $CaHPO_4$ ; (4) prevalence or abs. presence of the anhydrous forms of crystn. of the salts  $CaH_2(PO_4)_2$ ,  $CaHPO_4$ ,  $CaSO_4$ ; (5) the physicommechanical state of the product is defective and poor, and varies with and depends upon the proportions of  $H_2O$  and free  $H_3PO_4$  present, till the product reaches such a degree of pastiness and acidity as to be practically useless and unadapted for spreading by hand or mechanically. A. makes the following suggestions leading to technical prepn. of a good product: (1) The  $H_2SO_4$  used should have a temp. of 20–30°; (2) the duration of the mixing of the ingredients should not be too long; (3) for hard and nodulous phosphate rock, the concn. of the  $H_2SO_4$  should be about 54° Bé., and 55–6 for friable phosphate rock, depending upon their degree of humidity; (4) the following factors of parts per part of constituent found in the phosphate rock should be used in calcg. the amount of 53, 54, 55, 56° Bé.  $H_2SO_4$  resp., that is to be used:  $Ca_3(PO_4)_2$ , 1.14, 1.11, 1.09, 1.07;  $CaCO_3$ , 1.46, 1.43, 1.40, 1.37;  $Fe_2O_3(1/2)$  and  $Al_2O_3(1/2)$  3.34, 3.25, 3.20, 3.12; not detd., 0.12, 0.11, 0.10, 0.09; (5) the weighing should be exactly made, and preferably in the ordinary way, since automatic weighing app. does not always give good results, probably because of the variable pressure exercised upon the columns of phosphate rock meal by different degrees of packing; (6) the charge used in mixing should not contain more than a cwt. of phosphate rock meal, and the time of mixing should be about 15–20 sec.; (7) abnormally constituted superphosphates should not be dried out by application of heat. A. recommends the following means as preferable: (a) employment of exhaust fan connected with the reaction chamber, one hr. after completion of charging; (b) drying in the cold by use of absorbents such as burnt powdered gypsum or infusorial earth, which are inert, or the use of reacting substances such as powder of bone or very friable phosphate rock. These should be sparingly and carefully employed, and their use is at best a mere expedient, in nowise substituting a rational method of prepn. of superphosphate.

ROBERT S. POSMONTIER.

The storage of calcium cyanamide in bags. MEYER. Breslau. *Illust. Landw. Ztg.* 1917, No. 58, p. 347; *Biedermanns Zentr.* 47, 286–7(1918).— $CaCN_2$  takes up moisture and  $CO_2$  from the air increasing in wt. and vol. Caking and hardening also occur.  $CaCN_2$  cannot be kept any length of time in jute bags, for these are attacked by the caustic lime contained. The increase of vol. also bursts them. In expts. to det. whether storage in paper bags would be less disadvantageous it was found that the increase of wt. was the same in jute or paper and whether stored in fertilizer sheds or on a stable floor of peat. This increase was 10.9% after 8 wks., 11.4% after 15 wks.

and 11.7% after 21 wks. storage. Essential differences in the total N content did not result from differences in the manner of storage. The av. N content of the outermost layer was 10.93% and in the center of the bag 14.31%. The exterior hardened layer had increased in wt. by 36.1% while an increase of 4.0% only took place in the center. Conversion of cyanamide into dicyanamide to the extent of 7.9% took place in the outermost layer while this reached but 3.5% on the inside. Formation of dicyanamide seems to be greater in warm weather than cold. Small lots of  $\text{CaCN}_2$  may be preserved by emptying them from the bags and covering them in a dry room with a layer of Thomas slag meal or by several layers of dry fertilizer bags or dry peat.

ALBERT R. MERZ.

**Is phonolith a nitrogen fertilizer?** E. BLANCK. *Landw. Versuchs-Sta.* 90, 33 (1917); *Biedermanns Zentr.* 47, 283 (1918).—A series of samples of phonolith was investigated with respect to their content of total N and ammoniacal N in order to ascertain the basis of L. Hiltner's (*Landw. Jahrb. für Bayern* 5, 819 (1915)) assertion of the important properties of this eruptive-rock meal. The conclusion is reached that there is no N worth mentioning in phonolith. Also that the results of Hiltner are ascribable to the beneficial effects of  $\text{P}_2\text{O}_5$ .

ALBERT R. MERZ.

**Fertilizing effect and the utilization of some nitrogenous fertilizers.** C. EBERHART. Leipzig-Möckern. *Deut. Landw. Presse* 44, 441-2, 456 (1917); *Biedermanns Zentr.* 47, 151-5 (1918).—The fertilizing value and the comparative money value of a number of nitrogenous fertilizers brought into use as a result of the war were ascertained by a series of pot expts. of one year's duration using barley. The presence of thiocyanates in fertilizers is injurious to plants if the fertilizers are applied directly or during or shortly before the growing season.

ALBERT R. MERZ.

**Contributions to the bacteriological-chemical transformation of milk protein, especially galalith, in the soil.** E. BLANCK. *Landw. Vers. Sta.* 90, 17 (1917).—Expts. were conducted in a light sandy soil with galalith waste to ascertain the changes undergone by the protein of milk in the soil and its fertilizing value. The conclusion is that judging by the result of the cleavage of  $\text{NH}_3$  from the galalith the decompn. is a very slow process. No nitrification of the  $\text{NH}_3$  could be observed. Nor could a fixation of N in the form of bacterial protein be established. On the whole galalith would be a slow but steady source of N for plants in the sandy soil.

ALBERT R. MERZ.

**Manurial experiments with sea island cotton in St. Vincent in 1917-18.** S. C. HARLAND. *West Indian Bull.* 17, 69-79 (1918); cf. *Ibid* 16, 169-202 (1917).—Expts. with no fertilizer; N; P; K; P and K; N, P, and K; cottonseed meal; cottonseed meal, P, and K were conducted for 2 seasons. The number of flowers opening daily in every plot was recorded for a period of 5½ months, and the number of bolls opening daily in every plot was recorded for 53 days. All the manured plots showed increases over the unmanured in yield per acre, the greatest increase being upon the plot receiving K alone but a large gain was also shown on the complete fertilizer plot. The addition of P to K lowered the yield. No effect upon the time of maturing of the crop was produced by the fertilizers, likewise none upon the % of bolls to flowers. Results as to yield for the 1916-17 expts. closely parallel those of 1917-18.

R. B. DEEMER.

**Experiences in the cultivation of the sunflower.** C. KRAUS. München. *Deutsche landw. Presse* 44, 455-6 (1917); *Biedermanns Zentr.* 47, 256-8 (1918).—Cultivation of the sunflower resulted in complete failure as 90% of the heads had rotted on the plants at the time of harvesting. Chem. analysis of the seed of the sunflower gave 25.20% protein and 50.24% fat. Analysis of the hulls gave  $\text{H}_2\text{O}$  7.16%, protein 4.37%, fat 1.14%, N-free ext. 63.00%, crude fiber 20.73% and ash 3.60%. Cold pressing of the hulled, finely ground seeds gave 21.1% of a savory yellow oil. A second pressing raised the yield to 36.3%. The residues after the second pressing contained

2.04%  $H_2O$ , 37.96% protein and 27.60% fat. The yield of oil from sunflower seed is much less than that from rape or poppy. With regard to the utilization of the soil for the production of fat the sunflower is quite inferior to other oil-yielding plants. Its cultivation secondarily in gardens and in potato and turnip fields deserves consideration but it is doubtful whether it can be profitably raised as a large field crop.

ALBERT R. MERZ.

**Green-manuring experiments during the years 1910 to 1915.** W. SCHNEIDEWIND. *Arbeiten der deutsch. Landw. Ges.* 1917, No. 289; *Biedermanns Zentr.* 47, 246-51 (1918).—Expts. were conducted on a humus-containing loess loam with a crop rotation of wheat, sugar beets, barley and potatoes and on a dry sandy soil with a crop rotation of rye and potatoes. Various clovers, peas, beans and vetch, serradella, and blue and yellow lupines were used as green-manuring plants.

ALBERT R. MERZ.

**The question of the inoculation of grains and "Hackfrüchte."** M. HOFFMANN. Berlin. *Deutsch Landw. Presse* 44, 494-5 (1917); *Biedermanns Zentr.* 47, 188-9 (1918).—"U-cultures" (C. A. 13, 52, 53) should be tested by technical institutions in order to ascertain whether they are of value.

ALBERT R. MERZ.

**The inoculation of grains, "Hackfrüchten" and other cultivated plants with "U-cultures."** A. KÜHN. *Deutsch. Landw. Presse* 44, 467-8 (1917); *Biedermanns Zentr.* 47, 261-3 (1918); cf. C. A. 13, 52, 53.—Controversial.

ALBERT R. MERZ.

Waste pulp from New Zealand hemp (ANON.) 25.

**Fertilizer from gas liquor.** A. SCHUBERT. Swed. 44,244, July 10, 1918. The gas water from coke manuf. is mixed with crude tar and distd. at a temp. above 200°. The distillate is sepd. and  $H_2O$  added.

## 16. FERMENTED AND DISTILLED LIQUORS.

ROBERT WAHL.

**The bitter principles of hops.** W. WÖLLMER. *Bericht über die Tätigkeit der Wissenschaftlichen Station für Brauerei in München; Chem. Ztg.* 1917, No. 80/90, p. 149; *Biedermanns Zentr.* 47, 158-9 (1918); cf. C. A. 12, 1099.—The cryst. bitter principles of hops, the so-called  $\alpha$ - and  $\beta$ -bitter acids, have the formulas  $C_{21}H_{30}O_4$  or  $C_{26}H_{30}O_6$ . The supposition that both substances are not true acids but that their acid character is attributable to the presence of hydroxyl groups was confirmed and consequently these substances are more appropriately termed "humulone" and "lupulone." Humulone cleaves to form  $CO_2$ , isopentane and a hitherto unknown substance, the disubstituted "tetraoxybenzene,"  $C_{10}H_{14}O_6$ , taking up 6 atoms of H. Lupulone splits into the same isopentane and a substance  $C_{21}H_{34}O_4$  which was not obtained in the cryst. state but in the form of its benzene compd. and its oxidation product  $C_{21}H_{34}O_6$ . This substance shows the greatest similarity to humulone in its chem. and phys. properties, and is probably its tetrahydro deriv. Both substances behave exactly analogously on boiling with alkali, humulone forming humulin acid,  $C_{15}H_{22}O_4$ , and an unsatd. acid  $C_6H_{10}O_2$ , while the substance  $C_{21}H_{34}O_4$  forms dihydrohumulin acid and a caproic acid, substances which each possess 2 H atoms more than the analogous cleavage products of humulone. The proportion of humulone to lupulone in hops is subject to great variations. They are undoubtedly the bearers of the antiseptic and bitter powers of hops in the brewing process.

ALBERT R. MERZ.

**Malt extract with high diastase content.** I. POLLAK. Holl. 2,626, Oct. 1, 1918. Malt is repeatedly dried by heating in the presence of  $CaCO_3$ , and the dried residue is

then saccharified in the purified wort, with cooling, together with the diastase ext. previously obtained. Small quantities of strong reducing agents are added to prevent the growth of lactic acid bacteria. The product is evapd. to a thick sirup.

## 17. PHARMACEUTICAL CHEMISTRY.

W. O. EMERY.

An institute for coöperative research as an aid to the American drug industry. *J. Ind. Eng. Chem.* 11, 157-61(1918); cf. *C. A.* 13, 161, 246.—Letters are published from WILLIAM OHLIGER, B. L. MURRAY, FREDERICK FENGER, JOHN URI LLOYD, CHAS. E. VANDERKLEED, ALBERT C. CRAWFORD, ARTHUR D. HIRSCHFELDER and DENNIS E. JACKSON. E. J. C.

Preparation and chemical evaluation of tincture of strophanthus. HANS HELCH. *Pharm. Post* 51, 197-9(1918).—In order to det. whether the fat in strophanthus seeds produced the objectionable diarrhoeic properties of the tincture, a series of tinctures from normal and defatted Kombé seeds were prepd. by maceration with dild. and concd. alcs. and their effects studied. Dild. alc. was found to yield the best tincture; one prepd. therewith had a higher strophanthin content. Under similar conditions, the decompn. of the strophanthin to strophanthidin did not occur to such an extent as to lower its amt. below that in a tincture prepd. with concd. alc. The strophanthin content of the seeds was not influenced by the extn. of the fat with petroleum ether. The soly. of the oil is so low that the oil content of a tincture prepd. from normal seeds amts. to hardly 1 mg. in 10 drops. A tincture prepd. from normal seeds according to the method of the Austrian pharmacopoeia did not produce diarrhoea.

C. O. EWING.

The influence of the presence of stems and roots upon the total alkaloid content of the leaves of stramonium. GEORGE P. KOCH. *Am. J. Pharm.* 91, 11-6(1919).—Expts. show that the moisture content of the various portions of stramonium plants are as follows: Leaves 80 to 85%, secondary stems 87 to 92%, primary stems 85 to 87%, and roots 78 to 82%. When the whole plant, not including the root, is considered, the ratio of the leaf to the whole stem is about 47.5 to 52.5. In considering the leaf, stem and root, the leaf represented about 41% of the whole. The total mydriatic alkaloids, of the leaf and secondary stems when analyzed individually or the leaves with 10% of the secondary stems, run much higher than the U. S. P. requirement. The whole plant either with or without the root can be harvested and used for the commercial prepn. without fear of the total alkaloid content falling below 0.25%, which is the desired standard.

W. G. GAESSLER.

The early history of percolation. JAMES F. COUCH. *Am. J. Pharm.* 91, 16-25 (1919).

W. G. GAESSLER.

Churchill's tincture of iodine. History, experiments and improved formulas. HERBERT C. RAUBENHEIMER. *Am. J. Pharm.* 91, 37-45(1919).—Expts show that there is insufficient KI in the tincture completely to dissolve the entire amt. of I, that the proper amt. of KI to be added to the present N. F. tincture is between 5 and 6 g. per 1000 cc., and that a tincture with either of the following 2 formulas could be used with better results than the present prepn. of the N. F.: Formula No. 1: 16.5 g. I, 3.85 g. KI, 25 cc. water, sufficient alc. to make 100 cc. Formula No. 2: 16.5 g. I, 3.83 KI, 25 cc. water, sufficient alc. to make 100 cc. If the tincture is to be used immediately after dispensing, it is best to use the 3.85% KI, but if it is to be put away on the shelf until needed, as is the case in most drug stores, 3.83% KI will be sufficient. Another modification (Formula No. 3: 16.5 g. I, 3.3 g. KI, 3 cc. water, and sufficient alc. to make

100 cc.) will be found to be stable and can be made more readily than the tincture containing the 25 cc. of water because the alc. % has been increased; this greatly helps to dissolve the I.

W. G. GARSSLER.

**Neutral Dakin's solution:** diminution of the amount of boric acid used in its preparation. C. PAGEL. *Bull. sci. pharmacol.* 25, Pt. 2, 263-5 (1918).—The use of  $H_3BO_3$  and indicators in the neutralization of the excess of  $Na_2CO_3$  may be avoided by adding a soln. of  $CaCl_2$  after mixing the  $Ca(OCl)_2$  and  $Na_2CO_3$  solns., the  $CaCl_2$  being added in small portions until no further ppt. is formed. The  $CaCl_2$  may be prepd. by dissolving the  $CaCO_3$  pptd. in the reaction in the minimum amt. of HCl. The method has given satisfactory results in the hospital at Villemanzy.

M. HEIDELBERGER.

**Extracts and undetermined organic constituents of mistletoe:** their blood-pressure reducing power. BONNAMOUR AND NIQUET. Lyon. *Bull. sci. pharmacol.* 25, Pt. 2, 283-92 (1918).—Details for the prepn. of the alc. and aq. exts. are given. Mistletoe from the hawthorn (A), apple tree (B), and poplar (C) was used, all the exts. producing a fall in the blood pressure of the rabbit, (B) being the most active. (A) and (B) also caused a marked slowing of the pulse rate. (A) in aq. or alc., and (B) in aq. soln. were not toxic in the doses used, while (B) in alc. and both exts. of (C) caused convulsive movements and the death of the animals. A concn. of the depressor principles was obtained by dissolving each of the exts. in its own wt. of  $H_2O$ , pptg. inactive saponins by adding 9 vols. acetone, evapg. the acetone after letting stand and decanting, taking up the residue in  $H_2O$ , and pptg. with  $Ca(OH)_2$ . The ppt., which yielded inactive substances, was discarded and the filtrate made alk. and extd. with  $Et_2O$  to remove alkaloids, then acidified with  $H_2SO_4$  and again extd. with  $Et_2O$  to remove org. acids. The aq. liquid was then treated with  $\frac{1}{2}$  its vol. of acetone and satd. with  $(NH_4)_2SO_4$ , the acetone sepg. and carrying with it the undetd. org. constituents of the mistletoe, containing the depressor substances. After concg. *in vacuo*, sepg. from a trace of  $(NH_4)_2SO_4$  by taking up in abs. alc., filtering, and again concg., a soft ext. was obtained, which, when taken up in aq. acetone, caused a marked lowering of the blood pressure, the preps. from the original alc. exts. being particularly active. The concentrate seemed to be unattacked by alc. NaOH, but when evapd. at 50-60° with  $Ac_2O$  it yielded square crystals; at higher temps. a volatile substance is produced. Tracings of the animal expts. are given.

M. HEIDELBERGER.

**Detection of denatured alcohol in officinal opodeldoc balsam.** BOUCHER. *Bull. sci. pharmacol.* 25, Pt. 2, 295-6 (1918).—Melt on the  $H_2O$  bath, dil. 5 cc. with 10 cc.  $H_2O$ , add 10 drops satd.  $CaCl_2$  soln., filter, and distil 7-8 cc. of the filtrate, collecting 2 portions of the condensate of 2.5 cc. each. To 1 add KI-I soln. and aq.  $NH_3$ , a ppt. of  $CHI_3$  after 0.5 hr. being considered a positive test. To the other portion add 5 cc. 1%  $KMnO_4$  soln. and 0.2 cc.  $H_2SO_4$  and shake. After 5 min. shake with 1 cc. satd.  $(CO_2H)_2$  soln. and mix with 1 cc. concd.  $H_2SO_4$  and 5 cc. fuchsin bisulfite soln.; a rose-violet color after 15-30 min. indicates HCHO (Denigès' test). These tests are sufficient to detect the acetone or MeOH used in the denatured alc., and are negative with authentic opodeldoch balsam.

M. HEIDELBERGER.

**Saffron from Kosani.** VALDIGUIÉ. Commercial Bureau of the Army of the Orient. *Bull. sci. pharmacol.* 25, Pt. 2, 302-4 (1918).—The Macedonian article corresponds to the best French variety. The red and yellow varieties gave, resp.,  $H_2O$ , 8.5, 11.1%; ash, 5.1, 9.95%; ext., 58, 41.4%; coloring power, greater than 1:50000, 1:10000. The red variety is rich in crocein, while the yellow species contains very little. The filaments are very much more delicate than, for example, those of the Spanish variety, 50 weighing only 110-30 mg. Samples with excessive moisture are common. Other details of botanical and com. interest are given.

M. HEIDELBERGER.

**Horehound.** HENRI LECLERC. *Bull. sci. pharmacol.* 25, Pt. 2, 310-5(1918).—Historical sketch, from the earliest times to L.'s recent work. M. H.

**Concentrated sucrose solution as a general excipient in intravenous injection of irritant substances such as gold tricyanide, quinine and mercuric cyanide.** GEORGES ROSENTHAL. *Compt. rend. soc. biol.* 81, 919-20(1918).—Intravenous injection of 2 mg.  $\text{Au}(\text{CN})_3$  in 5 cc. concd. sucrose soln. was well tolerated. Little or no irritant effect was observed in the case of intravenous injection of quinine or  $\text{Hg}(\text{CN})_2$  in concd. sucrose soln. as an excipient. The use of this excipient is recommended as a general procedure for increasing the tolerance of the organism toward intravenous injections of various irritant substances. H. S. PAINE.

**Iodine soap and other iodine preparations.** N. O. ENGFELDT. *Svensk Farm. Tidskrift* 22, 309-14, 325-6, 341-7(1918).—Iodine soap is recognized in the Swedish Pharmacopeia but not generally recognized in the Pharmacopeias of other nations. It is prepared by working 7 g. I crystals into 73 g. soap. In the freshly prepd. soap there is hardly any free I. The I is combined mostly with the unsatd. fatty acids. In old soaps there is some free I, at most 4.7% of the I added is free. There is a change taking place in the prepn. as soon as it is compounded in which HI is formed. This reacts with the alkali so that about half of the I added is in the form of KI when the equil. has been reached. Glycerol in the soap plays no part in the state of I in the so-called iodine soap. The fats take up I in soln. In such prepn. as Jodi vasolimentum, Olementum Jodi, and Oleogenum jodi the I is mostly in the form of  $\text{NH}_4\text{I}$ . A. R. ROSE.

**Digitalis leaves: effect on activity of temperature in drying.** HERBERT C. HAMILTON. *J. Am. Chem. Soc.* 41, 125-9(1919).—Fresh leaves were gathered from the flowering and fruiting plants in July, divided into 3 equal amts. and treated as follows: (1) Extd. immediately with 95% alc. for moistening and then with 70% alc. to complete exhaustion; (2) dried in an oven between 70° and 90° (about 5 hrs.) and then extd. with 70% alc.; (3) dried in the air and partly in the sun for 4 days, then extd. with 70% alc. The tinctures were made to the same amt. on the basis of the oven-dried lot and assayed by the M. L. D. method on the frog (Houghton, *J. Am. Med. Assoc.* 31, 959(1898)). The fresh drug was found to be more toxic than the dried, and the high temp. in the oven drying caused a greater immediate deterioration than the air drying. CHAS. A. ROUILLER.

**Cinnamon bark from the gold coast.** ANON. *Bull. Imp. Inst.* 16, 146-7(1918).—A sample of cinnamon bark from the Gold Coast when distd. yielded 1.18% heavy oil separated from aqueous distillate and 0.30% light oil extd. by  $\text{Et}_2\text{O}$  from the distillate. The heavy oil had a sp. gr. 1.042, refractive index 1.603, aldehydes 86%. The entire oil yielded 68% aldehydes. R. L. SIBLEY.

**Balsam of Copaiba from Colombia.** ANON. *Bull. Imp. Inst.* 16, 147-9(1918).—This balsam is a semi-liquid oleoresin obtained from leguminous trees belonging to the *Copaifera*. The balsam was yellowish, acrid and of bitter taste. The sp. gr. was 0.961, acid value 79.8, ester value 11.7, yield of essential oil 45.5%. The balsam and volatile oil satisfied the requirements of the British Pharmacopeia and would be suitable for medicinal use. R. L. SIBLEY.

**Tobacco from Ceylon.** ANON. *Bull. Imp. Inst.* 16, II, 149-59(1918).—Twenty-six samples of tobacco were examd. and the analyses of 9 are reported as follows: moisture 14%, nicotine 1.7 to 4%, N 1.9 to 3.2%, ash 15.5 to 24.6%. The ash contained: CaO 27.1 to 34.8%, MgO 3.3 to 7.6%,  $\text{K}_2\text{O}$  6.7 to 22.7%,  $\text{Na}_2\text{O}$  1.9 to 5.0%,  $\text{SO}_2$  1.7 to 3.9%, Cl 7.6 to 15%,  $\text{CO}_2$  6.6 to 18.1%. The samples were all grown in the same locality and were subjected to the same treatment (air curing). Among the con-

clusions reached was that the soil was too rich in org. N but was deficient in potash salts. The analyses of 5 other samples received 2 yrs. later are also given. Estimates of the selling value of the samples are included.

R. L. SIBLEY.

Fiji bay oil. ANON. *Bull. Imp. Inst.* 16, 244(1918).—The leaves of the bay tree (*Pimenta acris*) are frequently mixed with those of 2 other forms (*Pimenta citrifolia*) which contains citral and *Pimenta anise* which contains anise) both of which are undesirable. One sample which possessed an odor of bay oil as well as an anise odor gave the following constants on examn.: sp. gr. 0.961, opt. rotation  $-1^{\circ} 58'$ . The oil was sol. in equal vol. EtOH and contained only 23% phenols as compared with 60% found in good bay oil. It was unusually rich in methyl esters.

R. L. SIBLEY.

Wild anthemis, a possible matricaria adulterant. C. W. BALLARD. *J. Am. Pharm. Assoc.* 7, 952-4(1918).—Histologic differences are described.

L. E. WARREN.

The seasonal variation of acidity, toxicity and alkaloidal content of three species of larkspur. O. A. BEATH. *J. Am. Pharm. Assoc.* 7, 955-8(1918).—The species studied were *Delphinium geyeri* (low larkspur) *D. glaucescens*, and *D. subalpinum* (tall larkspur). The altitudes at which the species flourish are in the order named, 5000-7000, 8000 and 9000-13,000 feet. The acid probably is an isomer of aconitic acid,  $C_8H_6O_6$ ; m.  $166-7^{\circ}$ ; non-toxic; optically inactive; sol.  $Et_2O$ , EtOH, and  $H_2O$ ; Ag salt detonates on heating; Et ester b<sub>m</sub>  $171-2^{\circ}$ . The acid exists combined with alkaloids and also free in considerable excess. *D. glaucescens* contains a white, cryst. alkaloid which is not very toxic. This combines with the non-toxic acid to form an amorphous complex which is highly toxic. In order to det. the stages of growth at which the plants were most poisonous whole specimens were selected, dried and carefully powdered. The drug was percolated with EtOH, the solvent evapd., the residue extd. with pet. ether to remove fats and resins, the crude alkaloidal residues were taken up in 70% EtOH and made up to definite vols. The solns. were intravenously injected into rabbits and the amts. necessary to produce symptoms or death noted. *D. glaucescens* is much less poisonous than the other species studied and the toxicity does not change with the advance in growth. *D. subalpinum* becomes more toxic as the flowering season approaches. *D. geyeri* and *D. subalpinum* represent extremes in size, yet the physical properties of the poisons sep'd. from them are very similar while the poison complex from the intermediate species, *D. glaucescens*, is markedly distinct from the others. The principal alkaloid from this species is cryst., optically active and is present at all stages of growth. *D. geyeri* yields amorphous alkaloidal products only. *D. subalpinum* contains 1 cryst. alkaloid in the early stages of growth but this soon becomes amorphous as the plant develops. In the detn. of the alkaloids care must be taken not to use alkali or too high concn. since decomposition may result. According to season *D. glaucescens* was found to contain from 0.25 to 0.6% of alkaloids; *D. subalpinum* from 0.3 to 0.7; and *D. geyeri* from 0.7 to 1.5%.

L. E. WARREN.

Continuous percolation under reduced pressure. J. G. BEARD. *J. Am. Pharm. Assoc.* 7, 964-6(1918).—Essentially a modified Soxhlet without the siphon discharge tube but with an outlet at the bottom as in percolators of the usual form is described.

L. E. WARREN.

Carbon tetrachloride as a solvent for fats. J. B. SNYDER. *J. Am. Pharm. Assoc.* 7, 966-7(1918).—The U. S. Pharmacopoeia directs the use of petr. ether for the extn. of fats and oils from certain drugs preparatory to making the fluidexts. The odor of this solvent persists on the drug, eventually appearing in the finished prepn., its use is expensive and a dangerous fire risk. S. finds that  $CCl_4$  is a satisfactory substitute from each of the objectionable viewpoints.

L. E. WARREN.

**Pharmaceutical war babies.** C. P. WIMMER. *J. Am. Pharm. Assoc.* 7, 967-71 (1918).—Review of the therapy and pharmacy of a number of medicaments introduced during the world war.  
L. E. WARREN.

**A report on Dakin solution.** I. A. BECKER. *J. Am. Pharm. Assoc.* 7, 971-2 (1918).—Specimens of Dakin soln. were prep'd. from assayed materials, the resultant preps. assayed and the products assayed again from time to time while in storage. A progressive loss in strength was observed, amounting to as much as 46% in 18 mo. The loss during the first few weeks is insignificant and in therapy may be disregarded.

---

The ignition of boric acid (BAGSHAW) 7. Terpenes and ethereal oils (WALLACH) 10.

**Antiseptics, etc.** G. B. PEGRAM. *Brit.* 117,451, June 20, 1918. The soly. in H<sub>2</sub>O, alc., acetone, etc., of the addition compds. of hexamethylenetetramine and I, especially the tetraiodo compd., is increased by the addition of KI or other halide of an alkali metal or NH<sub>4</sub>. The materials may be made up in tablet form or in soln. The products have antiseptic and germicidal properties.

**Synthetic drugs; intermediate products.** N. NAGAI. *Brit.* 117,486, July 14, 1917. The amino alc. PhCH(OH)CHMeNH<sub>2</sub>, prep'd. by condensing benzaldehyde with nitroethane and reducing the resulting phenylnitropropanol, is converted into a mixt. of mono- and di-N-Et derivs. by treatment with an Et halide, and the product is treated with a benzoyl halide or benzoic anhydride to give a mixt. of the benzoic ester of the di-Et compd. and the N-benzoyl deriv. of the mono-Et compd.; the two products are sepd., and the N-benzoyl compd. is converted into the benzoic ester of the mono-Et compd. by treatment with HCl. The two benzoic esters can be used as local anesthetics.

**Dry stable hemoglobin preparations from defibrinated blood.** F. SCALITZER. *Holl.* 2,571, Sep. 5, 1918. After hemolysis is complete, a neutral salt not acting on the oxyhemoglobin is added to the blood to prevent freezing when it is cooled below 0°.

**Blood-forming product.** SOC. ANON. POUR L'IND. CHIM. À BALÉ. *Swed.* 44,041, May 15, 1918. Blood is allowed to flow into a coagulating medium, the mixt. is boiled with high-proof alc., the ext. is freed from the greater portion of the alc. by evapn. at a low temp., the residue is mixed with H<sub>2</sub>O, the resulting emulsion is shaken with CHCl<sub>3</sub> or other highly chlorinated hydrocarbon, and the soln. obtained is pptd. with acetone to obtain therapeutically valuable products which are finally extd. by means of ether and sepd. by evapn. *in vacuo*.

E. H.

**Hydrochloric acid.** J. R. SCHULTZ. *Metal Record and Electroplater* 4, 364 (1918).—An illus. account of the modern process of manuf.  
C. G. F.

The Cottrell processes in the sulfuric acid industry. A. A. HEDMROD AND H. D. EGBERT. *Chem. Met. Eng.* 19, 309-14 (1918).—The Cottrell process is used both for cleaning the hot  $\text{SO}_2$  gases from the roasting furnaces in plants burning pyrites and other sulfide ores, and for removing and collecting acid mist in the exit gases from concentrators and absorption towers. Two forms of app. are used for the first purpose; one called the "plate" type and the other the "pipe" type. The former is used when the suspended matter in the gases is mainly dust and the temp.  $1000^\circ\text{F}$ . or more, and the latter at temps. up to  $600^\circ\text{F}$ . for the removal of fumes rather than dust. An app. used in connection with a zinc blende roaster collected 7600 lbs. material (Zn 22%, Fe 30%, Pb 2.2%, S 30%) in 24 hrs. from 17,500 cu. ft. of gas per min. at  $500^\circ\text{F}$ . The "plate" type of machine, used to purify the  $\text{SO}_2$  gases from the burning of 20-25 tons of pyrites per 24 hrs. at  $1100^\circ\text{F}$ ., yielded 900-1200 lbs. of  $\text{Fe}_2\text{O}_3$  dust per day. The "pipe" type of app. is used in the removal of acid mist. Lead and tile are employed in the interior construction of the precipitators. One installation collected 25 tons of  $40^\circ\text{Bé}$ . acid per 24 hrs. from the exit gases of a concentrator set of 22 cascade units producing 220 tons  $66^\circ\text{Bé}$ . acid per 24 hrs. 30,000 cu. ft. gas passed through the app. per min. at  $180^\circ\text{F}$ . Draft may be induced by a steam jet or a fan. In the former case the concn. of the recovered acid is low.

Leaching and filtration nomenclature. A. W. ALLEN. *Eng. Mining J.* 106, 990 (1918).—The writer distinguishes between terms of similar meaning, and discusses the difference in operation between vacuum filters and filter presses. A. BUTTS.

Muscle Shoals nitrate plant (FAIRLIE) 4. Dyes and the developments of British chemical industry 25. Rational preparation of superphosphates (AITA) 15. Annual review on the various metals, metal products, ore, etc., in 1918 9. Largest potassium plant in Europe (ANON.) 20.

Precipitating titanous acid. NORSKE AKTIESELSKAB. Norw. 28,088, July 23, 1917. In mfg. fireproof compds. of Ti, solns. containing salts of Ti, Fe, and other metals are reduced by the usual methods to produce tervalent Ti, and the product is then pptd.

Magnesium chloride and carbonate. H. W. C. ANNABLE. Brit. 117,483, July 13, 1917. Mg is sepd. from a mixt. of Mg and Ca carbonates, such as decomposed dolomite, by heating the said mixed carbonates, suspended in  $\text{H}_2\text{O}$ , under pressure with the requisite amt. of Ca, Ba, or Sr chloride. The  $\text{MgCl}_2$  thus formed may then be pptd. as carbonate or as oxide which latter may be further treated in suspension with  $\text{CO}_2$  to produce carbonate or hydrated carbonate of Mg. According to the provisional specification, the heating with an alk.-earth chloride need not be conducted under pressure.

**Anhydrous magnesium chloride.** E. A. ASHCROFT. Swed. 44,299, July 3, 1918. A suitable Mg compd. is suspended, mixed, or dissolved in a fused medium in the presence of Fe or Mn or other catalyzer (and Cl is introduced?).

**Calcium carbonate.** N. STATHAM. Brit. 120,219, July 26, 1917. Light pptd. chalk having a d. of 16.2-9.5 lb. per cu. ft. is obtained by disseminating a lime liquor through an atm. contg. considerable  $\text{CO}_2$  under pressure. The pressures mentioned are 20-80 lb. per sq. in. above atm., the lighter products being obtained by the use of the high pressure. A suitable app. is specified.

**Sodium sulfite.** L. DESCAMPS. Holl. 2,256, Dec. 1, 1917. Liquid  $\text{SO}_2$  is allowed to volatilize into a mixt. of  $\text{H}_2\text{O}$  and Zn dust, producing a cooling effect. After the reaction is complete NaOH of 45-50° Bé. is added to sep. the Zn with the minimum content of  $\text{H}_2\text{O}$ . The Zn is then completely sepd. by the addition of  $\text{Na}_2\text{CO}_3$ .

**Sodium cyanide.** H. P. EASTMAN. Can. 188,259, Jan. 14, 1919. An alk. earth cyanamide is caused to react with an alkali metal chloride above the m. p. of the latter and in the presence of  $\text{CaC}_2$ . The  $\text{CaC}_2$  prevents foaming and hastens the reaction. Cf. C. A. 13, 166.

**Treating zinc salt solutions.** P. FERRÈRE. Swed. 44,062, May 15, 1918. In the prepn. of ZnO from  $\text{ZnSO}_4$  soln. as an intermediate product, the soln. of the Zn salt (such as  $\text{ZnSO}_4$ ) is satd. with  $\text{SO}_2$  and the oxide of alk.-earth metal is added in amt. less than necessary to combine with half the  $\text{SO}_2$  present, and the  $\text{SO}_2$  is then added continuously, without pressure, together with the alk.-earth oxide, in the stated proportions, until all the Zn is present as dissolved  $\text{ZnSO}_4$ .

**Alumina free from iron.** NORSKE AKTIESELSKAB FOR ELEKTROKEMISK INDUSTRI. Norw. 28,901, Aug. 5, 1918.  $\text{Al}(\text{OH})_3$  is pptd. from Al minerals and salts by means of sol. sulfide. The addition of the sulfide is discontinued upon the appearance of black  $\text{FeS}$ .

**Nitrogen from air.** ELEKTRISITÄTSWERK LONZA. Norw. 28,962, July 29, 1918. Air is forced, in counter-current, through solns. of  $(\text{NH}_4)_2\text{SO}_4$  until the O content of the air is reduced to 1%.

**Fixation of nitrogen.** R. M. MCKEE. Can. 188,363, Jan. 21, 1919. A container having exposed interior walls of an alloy of approx. Ni 60%, Cr 12%, Fe 25%, is used in the N-fixation process. The container is durable and resistant and seems to act as a catalyzer.

**Decanting and settling chemical and other liquids.** W. CLIFFORD and JONES & ARWOOD. Brit. 117,472, May 24, 1917. In the sepn. and settlement of suspended matters from chem. and like mfg. liquids, providing at or near the top of the settlement tank a bucket or like vessel by which the liquid from the inlet is directed in an upward direction into a relatively large body of liquid within an open-bottomed guard chamber or well which directs the slowly moving liquid downward into the body of the liquid in the tank. In a modification, the bucket or like vessel is replaced by a funnel-shaped vessel carried at the end of the inlet pipe and adapted to direct the flow upwards.

**Recovering liquids used for separating solids of different specific gravities.** A. NAGELVOORT. Can. 188,397, Jan. 21, 1919. The sepd. solids are washed in a solvent of the separating medium which will not chemically react or combine therewith except to form the soln.  $\text{SnBr}_2$  is removed from solids by washing in liquid  $\text{CS}_2$ . Cf. C. A. 12, 129.

**Separating solids of different specific gravities.** ADRIAAN NAGELVOORT. Can. 21, 1919. Solids of different sp. gr. are sepd. in a soln. of a bromide and  $\text{CS}_2$ , then the solids are washed with  $\text{CS}_2$  and the excess  $\text{CS}_2$  required to provide a separating medium of the desired sp. gr. is distd. off from the resulting soln. Cf. C. A. 12, 129.

**Molded blocks of nitrides.** E. PODSZUS. *Holl.* 2,517, Oct. 1, 1918. In the manuf. of molded blocks of BN or TiN, the metals or their compds. are molded, sintered by heating, and then heated in an atm. of  $\text{NH}_3$  or the like to convert them into the nitrides.

**Platinizing pottery, etc.** F. J. KETTEL, A. GASCH and T. A. DEAN. *Brit.* 117,432, May 13, 1918. The article is covered with a soln. or emulsion consisting of  $\text{PtCl}_4$ , glycerol, and phenylhydrazine, heated to  $850\text{--}900^\circ$  to reduce the Pt to the metallic state and subsequently cooled gradually under ordinary atm. conditions. The ingredients are used substantially in the proportions of 3 g. of  $\text{PtCl}_4$  to 12 cc. of glycerol and 7 drops of phenylhydrazine. In prepg. the soln. or emulsion, the  $\text{PtCl}_4$  is dissolved in the least possible quantity of  $\text{H}_2\text{O}$ , the glycerol is added, and the mixt. is heated on a water-bath until it reaches the temp. of boiling  $\text{H}_2\text{O}$ , at which it is maintained for 1.5 hr.; the phenylhydrazine is then added slowly drop by drop and the mixt. stirred. Heating is continued until frothing ceases, *i. e.*, about 3 hrs.; or the liquid may be poured away from the froth.

**Fireproof and acid proof products.** TITAN CO. *Norw.* 29,010, Aug. 12, 1918. Ti acid and alkali hydroxide, with or without other substances, are heated to partial sintering.

**Vegetable glue.** C. BERGQUIST. U. S. 1,287,841, Dec. 17. An adhesive is formed of starch and  $(\text{CH}_3)_4\text{N}_4$ . On drying the adhesive gives a clear film.

**Design of transmission line porcelain insulators.** G. I. GILCHRIST AND T. A. KLINEFELTER. *Elec. J.* 16, 8-16(1919); illus.; cf. *C. A.* 13, 210.—The main causes for porcelain insulator failures are: improper distribution of dielec. field and of surface leakage; porosity; mechanical breakage; lightning; birds short-circuiting the line; unequal expansion of metal, cement, and porcelain; internal stresses in the material; and defective batches. Several old types and a new type of insulator are illustrated and discussed. The proposed type embodies: a surface conforming to the flow lines of the electrostatic field; rain-shed surface conforming to the equipotential surfaces; lines of mechanical stress parallel to the electrostatic flow lines; leakage resistance per shell about equal; and approx. equal capacity per shell. From a dielec. standpoint, a special cap appears desirable, but voltage characteristics under rain are the same whether for this or the line and tie wire, and cost and ease of replacement, cost of construction, etc., favor the line and tie wire construction. Advantages claimed for the new type of insulator are: When dry the corona and static formations are practically limited to the tie wire and line wire up to flashover voltage; when wet no corona or static formation occurs; leakage resistance per shell is increased gradually from the head to the center shell; voltage distribution per shell is equal when clean and in dry air; voltage distribution per shell is approx. equal under all operating conditions; it has high resistance to side pull for a given weight and given elec. strength (due to coincidence of flow line of electrostatic field and the mechanical stress lines); individual shell design is such that

when tested before assembly the surface conforms to the electrostatic flow lines; shape of individual parts and of assembled units affords protection from mechanical breakage and from complete failure during flashover in service; and each characteristic of the insulator affecting durability is treated uniformly throughout the line.

W. H. BOYNTON.

## 20. CEMENT AND OTHER BUILDING MATERIALS.

---

C. N. WILEY.

Dalen portland cement mills, Brevik (Norway). Largest potassium plant in Europe. *Farmand* 1918, No. 48.—The Dalen portland cement Mills, Brevik, Norway, will start mfg. cement Jan., 1919, and the company has a plant under erection for mfg. K salts for fertilizers as a by-product. The method used for obtaining the K is the one now in use in the American portland cement industry. The capacity of the plant is 150,000 tons cement and 25,000 tons K fertilizer yearly. G. HALLBERG.

Antiseptic treatment of timber. R. S. PEARSON. Calcutta. *Indian Forest Records* 6, Part 4, 128 pp.(1918).—Detailed data are given showing results of lab. and field tests of 12 different species of Indian woods when variously treated in open tanks and under pressure with 25 different salts and oils or combinations of these. Woods of all degrees of hardness were employed in order to det. their suitability chiefly for railroad ties, but also for fence posts, telephone poles, mine props, etc. Best results were obtained with various coal-tar creosotes. Solns. of various salts are not so serviceable in the wet climate where tests were made, but might be serviceable in the more arid localities. The treated hard and moderately hard woods as compared with untreated specimens stood up better in proportion than treated soft woods. C. O. EWING.

Typical specifications for non-bituminous road materials. PREVOST HUBBARD AND F. H. JACKSON. U. S. Dept. Agr., *Bull.* 704, 40 pp.(1918).—The various sizes broken stone products are given which may be used satisfactorily in constructing various types of roads. The forms of specifications adopted for non-bituminous road material are in general those recommended by the First Conference of State Highway Testing Engineers and Chemists (U. S. Dept. Agr., *Bull.* 555). J. J. SKINNER.

---

Non-bituminous road materials (REINECKE) 8.

---

Acid-resisting cement. A. E. HOLLEY and H. W. WEBB. U. S. 1,287,995, Dec. 17. An acid-resisting cement adapted for use in building chimneys or tanks is formed of sand 7,  $\text{CaSO}_4$  0.12, a 60° Tw. Na silicate soln. 3, ground stoneware 8 and ground blue brick 2 parts.

Acid-resisting cement. A. E. HOLLEY and H. W. WEBB. U. S. 1,288,413, Dec. 17. An acid-resisting cement suitable for use in building chimneys or tanks is formed of finely ground stoneware 8, sand 7, finely ground blue brick 2,  $\text{PbCO}_3$  0.5, and Na silicate soln. (60° Tw.) 3 parts.

Hydraulic cement and alkali manufacture. PATENTAKTIEBOLAGET JUNGNER'S KALI-CEMENT. Brit. 117,460, July 11, 1918. In the manuf. of cement and alkali from feldspar or other alkaliferous silicate minerals and lime or substance contg. lime,

the mixt. is first heated by means of fuel to such a temp. that the  $\text{CO}_2$  is driven off and the calcined mixt. is then introduced into an elec. furnace in which the heating is continued until cement is formed and the alkali driven off as vapor which is condensed and collected. The first heating may be conducted in a rotary furnace up to  $900^\circ$ , and the second heating in an elec. resistance or radiating furnace up to  $1400^\circ$  or higher. A suitable elec. resistance furnace comprizes a receptacle mounted on trunnions and lined with fireproof clay and containing a number of vertical plates of elec. conducting material such as C or graphite and sepd. by rectangular sticks of C and non-conducting pieces alternately. Screws are provided for holding the plates in contact with the sticks. Condensation of the alkali may be obtained on the furnace cover or in a cooled chamber connected by a pipe with the furnace interior. The deposition may take place in  $\text{CO}_2$  or an atm., such as the flue gases from the calcining chamber, containing  $\text{CO}_2$ .

**Concrete.** W. J. STEWART. Brit. 117,504, July 25, 1917. Concretes of low sp. gr. are formed by firing molded elements of a shapable material such as vitreous clay, or non-vitreous clay subsequently receiving a vitreous coating and sanding. The aggregate is prepd. by molding clay in uniform molds, e. g., of spherical form, burning, glazing to render non-absorbent, and causing sand to adhere to the glaze before cooling to produce a rough surface. Such aggregates, in differing forms and sizes, from a quarter to three-quarters of an in. in diam., are employed with sand and lime to constitute concretes, which if they are to be molded, may have the aggregate elements systematically arranged according to size in the mold. The matrix material, such as cement, is caused to flow in from below upwards preferably under pressure so as to displace air and obviate bubbles.

**Concrete.** C. E. BARGLEBAUGH. U. S. 1,287,827, Dec. 17. A concrete mixt. is formed of cement 1, ground lava rock (100 mesh) 1.5 and aggregate (about 1 in. diam.) 3 parts. The concrete is relatively light and is stated to be waterproof.

**Soluble potassium compounds from cement-mill dust.** A. R. MERZ. U. S. 1,288,437, Dec. 17. Portland cement mill dust is ignited in an oxidizing atm. to increase its  $\text{H}_2\text{O}$ -sol. potash content. The pat. is dedicated to the public for free use.

**Composite building material.** E. VIENS. Can. 187,899, Dec. 10, 1918. A fireproof, resilient building material composed of portland cement, asbestos fiber,  $\text{Ca}(\text{OH})_2$ , sawdust and siliceous material requires a force of 450 pounds to pull therefrom a 2-inch nail driven 1.5 inches therein.

**Tarred paper.** R. P. PERRY. U. S. 1,288,158, Dec. 17. A material suitable for use as roofing or sheathing is formed of superposed sheets of paper which contain different proportions of bituminous material.

**Tarred felt.** R. P. PERRY. U. S. 1,288,159, Dec. 17. Finely divided asbestos or other fibrous material is added to comminuted pitch, asphalt or other bituminous substance and while the mixt. is in soft adherent condition it is pressed into sheet form.

## 21. FUELS, GAS, TAR AND COKE.

J. D. PENNOCK.

**Fuels and their uses.** VERSEFUY. *J. des usines à gas*, Aug. 20, 1917; *Het Gas* 38, 126-31 (1918).—A lecture. JULIAN F. SMITH.

**Methods for more efficiently utilizing our fuel resources.** C. G. GILBERT AND J. E. POGUE. *Gen. Elec. Rev.* 22, 72-81 (1919); cf. *C. A.* 12, 1241, 2683.—The wastefulness of burning raw coal is condemned and strong recommendation is made that the coal products industry be expanded to furnish a greater amount of prepared fuel in both solid and gaseous states. Details are given. C. G. F.

**Recent methods for the study of the chemical composition of coal.** A. MAILHE. Toulouse. *J. des usines à gaz*, Aug. 5 and 20 and Sept. 5, 1917; *Hel Gas* 38, 151-5, 177-82 (1918).—A lecture. JULIAN F. SMITH.

**Calorific values and ash yields of coal samples.** T. J. DRAKELY. *Gas World* 69 (Coking and By-products Sec.), No. 1789, 21 (1918).—A study of the influence of impurities upon the calorific value of coal. Samples of the same thoroughly dried and crushed coal were taken and the ash content varied; the calorific value being detd. in a Mahler-Cook bomb calorimeter. In order to effect complete combustion of the mixts. which contained only small amts. of coal, sufficient pure naphthalene was mixed therewith to give approx. the same rise in temp. as with the coal samples, the heat due to the combustion of the naphthalene being deducted from the total. With a total ash content of 3.38% the calorific value was 14,191 B. t. u.; with 13.89%, 11,346; with 24.44%, 8,520; with 34.95%, 5,675; with 45.46%, 2,821; zero calorific value was reached with 56% of ash. Tests with other coals showed the same general calorific decline with upward ascent of the % of ash. In the purchase of coal according to specifications, it is usual to correct the price for variations in calorific value and ash and moisture content. It might be argued, from the results of the test, that the ash content adjustment of the price was unnecessary, as it incidentally forms the basis of the calorific value correction. However, in boiler practice, it was found that the increase in evapn. observed with a cleaner sample of the same coal was not directly proportional to the decrease in the amt. of inert matter in the coal. Hence the correction of price according to the variations in the % of ash as well as calorific value is essential when coal is bought for industrial purposes on a specific basis. J. L. WILBY.

**Selecting coal for power plant use.** ROBERT JUNE. *Elec. Rev.* 74, 94-7 (1919).—This article points out the characteristics of various coals, and the influence of coal upon furnace-chamber proportions. Numerous curves and tables are included.

C. G. F.

**Coal conservation in relation to gas manufacture.** TIM DUXBURY. *Gas J.* 144, 302-8 (1918); *Gas World* 69, 262-3 (1918).—Results of further tests on steaming in Dempster-Toogood vertical retorts in which the objective was coal conservation. If the results as given hold good, 30,000 tons of coal will be saved annually. The make of gas per ton of coal from the March to Sept. quarter shows an increase of about 80% with a decrease in the calorific value of only 22%. The gas is now of 450 B. t. u. and the lighting effect is better than from 600 B. t. u. gas. On a B. t. u. basis the efficiency is also greater for gas heaters. About 22,000 cu. ft. of gas is being produced per ton of coal, and the coke yield is remarkably high, 14.5 cwt. More tar and NH<sub>3</sub> are being produced; the latter is weaker, probably due to the use of too much steam in steaming. The gas is also more free from S than previously.

J. L. WILBY.

**Briquetting small coal, coke breeze and coal washery slimes.** J. A. YEADON. *Gas World* 69 (Coking and By-products Sec.), No. 1789, 21-2 (1918).—A profitable method of utilizing coal and coke wastes by the manuf. of small ovoid briquets for domestic use, pitch being the most suitable binder. In the ovoid form, the smallest sizes and the most inferior qualities of coal even when containing as much as 20% of ash and 10% of moisture, can be profitably utilized. Coke breeze alone can be used with 8% of pitch.

J. L. W.

**Experiments in the distillation of heath sod.** ANON. *J. des usines à gaz*, Oct. 5, 1917; *Hel Gas* 38, 161 (1918).—A yield of 23.78% gas and 22.84% charcoal (calcd. from the gross wt. as delivered to the works) was obtained by distg. heath sod. The gas is of good enough quality to be mixed in equal proportions with coal gas. The charcoal is of good quality, bringing 25 to 30% better prices than pine charcoal.

JULIAN F. SMITH.

**Low-temperature carbonization and its products.** F. MOLLWO PERKIN. *Gas World* 69, 385-6(1918); *Engineering* 106, 746-7(1918).—A discussion presented before the Institution of Petroleum Technologists, on how best to utilize the various sources of oil in shales, poor coal, lignite, peat, etc. The character and quality of the products obtained by the carbonization of bituminous minerals depends mainly upon the temp. and the character of the raw material. On the whole, however, low temp. yields olefins and paraffins, and high temp. aromatic hydrocarbons. In horizontal retorts the av. temp. is 1100°; in vertical retorts, 1300-1400°. The main products of low-temp. and high-temp. carbonization, resp., are as follows: gas 5000-12000 cu. ft. per ton of coal, the latter being richer in H;  $(\text{NH}_4)_2\text{SO}_4$ , 10-20 lbs.; tar or crude oil 20-11 gals., in rich cannels it may rise to 60 gals. Financial success of low-temp. practice is possible on 3 lines: (1) by production of oil and smokeless fuel; (2) by production of oil and conversion of the fuel residue into power gas; (3) by production of oil, using a portion of the residue as domestic fuel and gasifying the remainder. Some comparative analyses are made of the products obtained by the Tarless Fuel Syndicate, carbonizing at 500° and by another company working with Glover-West retorts at about 1400°: coke, volatile matter 9.87-1.31%, fixed C 74.5-86.9, ashes 12.59-9.27, N 2-1.5, gas per ton 128,000-175,000 cu. ft., B. t. u. 139-132,  $(\text{NH}_4)_2\text{SO}_4$  101-23 lbs. Statistics are given in regard to shale distn., which is primarily a low-temp. operation. Another source of oil is lignite, which on distn. yielded 33-35 gals. of crude oil per ton, the coke proving satisfactory in a suction gas plant. With regard to peat, the greatest trouble was drying. By distg. Scottish peat containing 14.6% moisture and 53.5% volatile matter with superheated steam right down to C, there were obtained 1.9 gals. of spirit, 13.8 gals. fuel oil, 1.6 gals. phenols, 50 lbs. retort C, 2.5 gals. wood spirit, 23.8 lbs. acetate of lime and 8 lbs.  $(\text{NH}_4)_2\text{SO}_4$ . Also in *Gas J.* 144, 658-60(1918). J. L. WILEY.

**Report of the gas investigation committee to the Institution of Gas Engineers.** ARTHUR SMITHHELLS, *et al.* *Gas J.* 144, 235-49, 291-9(1918).—Three important domestic applications of gas through the ring-burner, the incandescent upright mantle burner, and the gas heater, are discussed. In the ring-burner tests various kinds of gases ranging from 530 to 241 B. t. u. were used. The consumption per hr. was 14-31 cu. ft. The conclusions from this test in boiling water are that flame contact is essential for high efficiency and that the efficiency is almost independent of the rate at which the gas is burned, between the limits of 10 and 25 cu. ft. per hr., also that efficiency is practically independent of compn., inerts or calorific value, but to deliver a sufficient number of B. t. u. in a reasonable time without abnormal pressures the gas used should be of moderately high calorific value. The efficiency of ring-burners varies considerably with the type; lighting back occurred with some burners with gas of 400-500 B. t. u. However, a wide variation in grade or compn. of gas can be made without impairing the efficiency of ring-burners now in use. In the lighting tests various kinds and qualities of gas ranging from 615 to 314 B. t. u. were used. The variations obtained from the richest to the poorest gas were: B. t. u. per cu. ft. of gas and air mixt. before burning, 88.2-86.1; per cu. ft. of combustion products, 91.9-97.2; cu. ft. of gas consumed per hr., 4.5-7.3; candles per cu. ft. at point of max. efficiency, 14.8-6.8. It was found important that the zone of active combustion be made to fit closely the mantle by either varying the gas consumption or the degree of aeration. This was found difficult with gases below 450 B. t. u. and about 600 B. t. u. The influence of inerts on gas of low calorific value was marked, but was negligible with medium heat values, the max. illumination being found at 525 B. t. u. The results show no preference for rich gas, rather the contrary. The gas heaters were measured by their radiation efficiency. The evidence obtained points to the conclusion that a difference in the grade or compn. of the gas supplied, within wide limits, does not cause any considerable

difference in the radiant efficiency of a gas fire, provided that the mechanical construction will allow sufficient gas to be passed, so that the same number of B. t. u. per hr. can be supplied. Also in *Gas World* 70, 53-4 (1919). J. L. WILBY.

Report of the forty-sixth general meeting of the Netherlands Association of Gas Manufacturers. *Het Gas* 38, No. 11a, 104 pp.—This report contains, aside from the proceedings of the discussions incident to the meeting, 3 addresses of a technical nature which do not seem to contain anything new: The washing of benzene in gas plants. G. F. VAN LIMBROCH VAN DER MEERSCH. Amsterdam (pp. 44-7). Old and new methods for the preparation of ammonia. ALPH. STEGER. The Hague (pp. 49-57). The analysis of coal tar according to the requirements of the Imperial Bureau of Coal Distribution. F. VAN OOSTROM MEIJES (pp. 60-2). JULIAN F. SMITH.

Some observations concerning (A) liquid purification of, and (B) simultaneous recovery of sulfur and ammonia from coal gas. P. PARRISH. *Gas J.* 144, 413-20 (1918); *Gas World* 69, 300-4 (1918).—The process of liquid purification contemplates the complete purification of gas by effecting the combination of the acid and alk. impurities to form salts which are readily sol. in water or weak ammoniacal solns. in circulation in a series of suitable towers. Since the acid impurities preponderate,  $\text{NH}_3$  must be added to obtain the necessary combination. Four operations are involved: (1) purification of the gas, (2) dissociation of the  $\text{NH}_3$  compds. in order to remove the acid gases from the foul liquor, (3) distn. of the purified liquor with production of  $\text{NH}_3$ , which is used in the scrubbers, (4) utilization of the acid gases by combustion for the production of  $\text{SO}_2$  and later  $\text{H}_2\text{SO}_4$ , or recovery of the  $\text{H}_2\text{S}$  as Claus S. From equations and data given, it is seen that there must be removed per ton of coal 13 lbs.  $\text{H}_2\text{S}$ , 30.6 lbs.  $\text{CO}_2$ , 0.74 lb.  $\text{CS}_2$  and 1.67 lbs.  $\text{HCN}$ . To effect this removal 38.08 lbs.  $\text{NH}_3$  will be required, or 5.07 times the quantity of  $\text{NH}_3$  in the gas, taking as a basis 30 lbs. of 25%  $(\text{NH}_4)_2\text{SO}_4$  or 7.5 lbs.  $\text{NH}_3$  per ton of coal. In addition to this, P. recommends circulating 7 times as much  $\text{NH}_3$  as is available in the gas in order to establish a reserve against variations. Besides this disadvantage and source of loss, there is mentioned another in connection with the distg. plant which, as is shown, must deal with a quantity of over 80,000 gals. per day of 1.39%  $\text{NH}_3$  liquor, and this from only a 250-ton per day plant. The details of design and arrangement of plant are given. It is calcd. that the capital cost of the plant would be no more than for a series of purifiers for dry purification, nor would there be very much difference in the cost of liquid and solid purification with the advantage that the former is more complete. A brief description is given of each the Claus and Burkheiser processes for recovering the  $\text{SO}_2$  as  $\text{H}_2\text{SO}_4$ . J. L. WILBY.

Review of the preliminary working tests of Settle's downward-steaming process for intermittent vertical retorts. ANON. *Gas J.* 144, 256-8 (1918).—Excellent results have been obtained in a series of tests carried out at the Truro Gas Works on a process devised by Thomas Settle for the downward steaming of intermittent vertical retorts. The additions to the retorts required to work the process comprize superheating coils and steam supplies on the top of the setting, and valve-controlled connections between the bottoms of the retorts. The steam at 30 lbs. pressure and superheated to 300° F., is admitted at the top of the retort through a circular knife-edge aperture 0.25 in. in diam. in a disk fitted into the steam pipe and thence into a clear place of about 2 ft. in the retort above the charge. Its velocity is repeatedly checked, its temp. is further raised, and instead of impinging on the incandescent coke at a high velocity that favors by-passing through any fissure in the charge, it approaches at a slow speed in a compact body equally diffused over the entire area. Steam is turned into each charge in succession, over the last quarter of a 12-hr. period, travels downward to the bottom connection, and thence to the base of a fresh charge, through which it travels upward to

the gas outlet. Thus, each charge receives 3 hrs. steaming down and 3 hrs. blue gas up. The advantage of the highly heated upward current of blue gas is a diln. of the rich gases without absorption and loss of heat, and protection of them from decompn. Consequently, the pitch in the tar falls below 40% and the yield of  $\text{NH}_3$  rises 30%. There is a remarkable decrease in the temp. of the gases at the exit, an av. of  $130^\circ \text{F.}$  being found, proving that the "dew-point" has been brought back from the usual position, somewhere in the foul main or close up to the interior of the retort. This effectively prevents deposits of  $\text{NH}_4$  salts in the hydraulic main. The steam in its descent and its conversion washes out the residual gases from the coke, and the diffusion of the blue gas in the freshly charged retort creates a new atmosphere inside the retort which is worthy of further study. The high proportion of H and  $\text{CH}_4$ , and the low content of CO, indicate new conditions. A fair sample of the gas shows in %:  $\text{CO}_2$  2,  $\text{O}_2$  0.7, CH 3.5, CO 4.8,  $\text{CH}_4$  32.1,  $\text{H}_2$  48.7,  $\text{N}_2$  8.2. The objective was a uniform 500 B. t. u. gas; it was found possible to keep within the limits of + or - 10 B. t. u. and to produce 10 million B. t. u. per ton of coal, or 20,000 cu. ft. of gas, with 12 gals. of tar oils and 30 lbs.  $(\text{NH}_4)_2\text{SO}_4$ . There is real economy here in the saving of about 25% of coal, as formerly about 14,000 cu. ft. of gas were made. The temp. of the charge during down-steaming ranged from  $1000^\circ$  at the bottom to  $800^\circ$  at the top. The loss of weight of coke due to the use of steam was 2.34%. The av. temps. in the settings outside the retorts were: bottom zone  $1330^\circ$ , middle  $1170^\circ$ , top  $1120^\circ$ . The process is applicable to any large-scale installation of intermittent vertical retorts or on small gas works.

J. L. WILBY.

**Economizing coal in gas manufacture.** FREDERICK SHEWRING. *Gas World* 69, 261(1918).—A suggestion for conserving coal by means of steaming the charges in horizontal retorts for production of blue water-gas.

J. L. WILBY.

**Steaming horizontals at Leek.** R. H. GINMAN. *Gas World* 69, 263-4(1918).—Av. working results show a yield of 16,200 cu. ft. of 490 B. t. u. gas per ton of coal. Eight hr. charges are being worked, yielding per ton: tar 14 gals. sp. gr., 1.14;  $\text{NH}_3$  liquor, 48.7 gals.; coke, 9 cwt. The compn. of the gas in % is: H 50.4,  $\text{CH}_4$  22.6, unsatd. hydrocarbons 2.9, CO 10.6,  $\text{O}_2$  0.8,  $\text{CO}_2$  5.2, N 7.5. A saving of 514 tons of coal was made in Aug. and Sept., 1918.

J. L. WILBY.

**Steaming in horizontal retorts.** JAMES K. LAW. *Gas J.* 144, 425(1918).—Steaming expts. have resulted in a saving of about 22% of coal, with a gas yield of 14,470 cu. ft. per ton of coal. The advantages are: the removal of the necessity of scurfing the retorts and cleaning the pipes; the quality and quantity of coke is as great as before; the tar, liquor and other residuals are unaffected; while the quality of the gas is very satisfactory.

J. L. WILBY.

**Labor-saving removal of clinker from gas furnaces.** G. FRÈRE. *Gas J.* 144, 469(1918).—The principle of the method is simply the removal of the ash as it is formed in the producer, which is required to have vertical walls. The result is attained by the use of a horizontal grid consisting of square Fe bars placed 1-1.25 in. apart. These bars are bent over at each end, and rest at the back of the furnace in a cast-Fe setting of ratchet formation; the space between each 2 teeth serving as the seat for the bar. The other end of each bar projects from the front of the producer below the door by which the declinkering is done. Here the bars rest in recessed parts of a plate attached to the front of the furnace by pins, and divided horizontally into 2 parts for ease of removal. The end of each bar projecting through the plate is fitted with a small rod, connected to a common lever, which is set in motion at suitable intervals by a motor. The lever is adjusted so as to give 6-10 quarter turns within a few secs., thus dislodging the ash which cannot collect in sufficient quantities to form large masses of

clinker customary in gas producers. The process may be promoted by the constant delivery under the grid of from 5-600 g. of steam per kg. of coke, the steam having no effect on the efficiency of the producer.

J. L. WILEY.

**Modern water-tube boilers in gas works.** E. DAVIES. *Gas J.* 144, 509(1918).—Some minor innovations in water-tube boilers for supplying steam to blue water-gas plants.

J. L. WILEY.

**"Pleno" gas.** D. STAVORINUS. Amsterdam. *Het Gas* 38, 155-60(1918).—The name "Pleno" gas was applied by Helps (*C. A.* 12, 1246). It is a gas dild. to a heat value of about 3000 cal. per cu. m., according to Brit. patent 111,495 (*C. A.* 12, 992). The importance of this type of gas is in the widespread effort to obtain the right to supply gas of low heat value in cities. Gas yielding as low as 3600 cal. per cu. m., can be used in appliances now in use, by proper regulation. While the vol. consumed is higher, the number of cal. required is lower than for a richer gas, and thus the useful effect is greater.

JULIAN F. SMITH.

**Manufacture of gas from wood and peat.** E. ORT. Zürich. *J. Gasbel*, Nov. 17, 1917; *Het Gas* 38, 103-8(1918); cf. *C. A.* 12, 860.—Wood and peat differ from coal and crude oil in the high moisture content (in peat sometimes as high as 90%). For making gas, they should be at least as dry as ordinary air (about 20% moisture). Above about 280° the carbonization of wood is exothermic. Consisting mostly of cellulose and lignite, wood and peat have a high O content and low calorific value. Most of the O comes off as CO<sub>2</sub> and CO, so that the gas contains 20 to 30% of each of these constituents. It contains only about 15% of CH<sub>4</sub> and 5% of heavy hydrocarbons. While it is theoretically possible to increase the heat value by passing the gas over glowing charcoal to reduce CO<sub>2</sub> to CO, in practice there is as much loss by decompn. of hydrocarbons as gain by formation of CO. By passing the crude gas, containing tar and steam, over glowing charcoal, some water gas is obtained; but even this method does not enrich the gas sufficiently to be practicable. Better results can be obtained simply by distg. well dried material in horizontal or inclined retorts not more than half filled. If each charge is drenched with tar from preceding charges, the yield of hydrocarbons is somewhat increased. The CO<sub>2</sub> can be removed by dissolving in H<sub>2</sub>O under pressure, or by absorption in lime water. The coke from peat is friable and has little value. The results obtained from peat vary a great deal more than those from wood.

JULIAN F. SMITH.

**The efficiency of gases of various composition in boiling experiments.** J. P. WIBAUT AND H. DE LEEUW. Amsterdam. *Het Gas* 38, 225-8(1918); *Chem. Weekblad* 15, 1278-9.—The efficiency of various gases of high and of low calorific value was tested by the method of heating a known amt. of H<sub>2</sub>O to boiling. The poorest gases have the lowest efficiency, but the difference is relatively slight. Thus, a coal gas and a water gas, differing 40% in calorific value, differed only 6% in efficiency.

J. F. SMITH.

**Energy losses.** J. RUTTEN. THE HAGUE. *Het Gas* 38, 279-82(1918).—A discussion of energy losses in gas works, and how to attain and maintain high working efficiency.

JULIAN F. SMITH.

**Increasing the concentration of ammonia liquor.** J. RUTTEN. The Hague. *Het Gas* 38, 282-3(1918).—The method of washing NH<sub>3</sub> from gas by washing first with dil. liquor and then with H<sub>2</sub>O must be used with caution, since careful control is required. The procedure for a rotary washer should be to det. the strength of the liquor in each compartment, and the content of volatile NH<sub>3</sub>; make the same detns. in the weak liquor to be used; and add it to that compartment in which it will yield a stronger liquor. The Baumé is not sufficient for detg. volatile NH<sub>3</sub>; it must be detd. directly.

JULIAN F. SMITH.

**Benzene as a motor fuel.** S. E. WHITEHEAD. *Gas J.* 144, 615-6(1918).—The four requirements for a suitable motor fuel are: (1) Easy starting from cold; (2) absence of objectionable odor, both in the fuel itself and in the exhaust, and no liability to cause excessive corrosion of any part of the engine; (3) no liability to form deposits in the cylinders and valve passages; (4) economical consumption. Benzene starts from the cold less easily than gasoline on account of its much lower vapor pressure. This can be overcome by adding a sufficient amt. of gasoline or of  $C_2H_2$ . Com. 50/90 benzene will not freeze above  $-10^{\circ}$  C. and the addition of a small proportion of gasoline considerably reduces the f. p. The question of odor depends upon (a) completeness of combustion; and (b) S content of the fuel. (a) is controlled by the proper adjustment of air supply. Gasoline contains on an av. 0.05% or 25 grains per gal. of S, whereas an av. 65's crude benzene contains up to 1% each of  $CS_2$  and  $C_4H_4S$ . The bulk of the  $CS_2$  is removed in the forerunnings; and the  $C_4H_4S$  can be very easily reduced by thorough washing with  $H_2SO_4$ , or by the chlorination process of Dutt and Hamer (*C. A.* 12, 2683). By these means a rectified product can be obtained containing 0.1%  $CS_2$  and 0.2%  $C_4H_4S$ , or a total S content of 90-95 grains per gal. Tests on coke-oven benzene, containing varying amts. of S, showed that the S in benzene need not be feared either as a source of objectionable odor or as a cause of corrosion of the engine. Deposits are of 2 kinds—C resulting from incomplete combustion, and resinous matter formed by polymerization of hydrocarbons. The former can be avoided by proper adjustment of the air supply, the latter by proper refining of the crude benzene to remove such products as cyclo- and dicyclopentadiene and coumarone which are readily oxidized to resins. Benzene is more economical both in power output per gal. and thermal efficiency of the engine. Tests show that benzene, used on gasoline engines under similar conditions of compression, etc., gives 10-20% more power and 20% more mileage per gal. than gasoline. The thermal efficiency and power output of the engine may be further increased by increasing the compression; compressions of 150-160 lbs. may be employed without danger of preignition. Benzene offers also other advantages. The explosive range of mixts. of benzene vapor and air is nearly twice that of gasoline; consequently troubles from too weak or too rich a mixt. are considerably reduced. The rate of combustion of a benzene mixt. is less than of the gasoline mixt.; this results in the elimination of knocking in an engine running at low speed. The higher flash-point of benzene makes it safer in handling and transport. Since benzene and alc. are miscible in all proportions, and gasoline and alcohol are not, another source of good fuel is made available in case gasoline production decreases. There is now used very successfully on the Continent a mixt. of 80 l. 95% alc., 20 l. benzene, and 200 g. naphthalene.

J. L. WILEY.

**Future of benzene.** D. R. WATTLEWORTH. *Gas World* 69, 345(1918); *Am. Gas Eng. J.* 109, 588(1918).—The article deals with the use of benzene as motor fuel. The usual complaints of gumming, corroding, freezing and water are discussed and the customary remedies suggested.

J. L. WILEY.

**Washing light oil fractions from coke-oven gas.** F. D. SCHREIBER. *Gas Age* 43, 22-4(1919).—Details of a practical and economical method used at the Koppers plant of the Brier Hill Steel Co., Youngstown, Ohio, for washing the crude light oil fractions. After the usual acid wash, lime is used in place of caustic as the neutralizing agent. For washing benzene there is used to each 5000 gal. charge 25-40 lbs. lime containing about 97% active  $CaO$ . The lime is slaked with a small amt. of water several hrs. before using, and when ready for use is mixed with 75 gals. of water. This is then added to the agitator and stirred for 30 mins. The unused lime and  $CaSO_4$  are drained off together with the water added, and then the charge is washed down with 100 gals. of water. Sometimes it is necessary in order to neutralize the last traces

of acid to use 5-8 gals. of NaOH of strength 80-90 g. per l. If care is used in making these washes very good results will be obtained. The acid consumption will vary between 0.4-0.45 lb. per gal. of crude product and the loss will be not over 3.5% by vol. of the benzene charged. For washing toluene 75-100 lbs. of lime are required to neutralize the large amt. of acid which is mechanically held by the toluene. The acid consumption should not exceed 0.2-0.25 lb. per gal. of crude product, and the loss can be easily kept under 1%. For washing solvent naphtha 75 and 50 lbs. of lime are added at different times. The acid consumption should not exceed 0.25 lb. of product washed, and the loss not over 8%.  
J. L. WILEY.

Coke plant producing gas for domestic use. ANON. *Gas Age* 43, 11-2(1919).—A good example of by-product coking practice in connection with supplying a local demand of both gas and coke. The plant is the Minnesota By-product Coke Co., situated in St. Paul. The plant consists of 65 Koppers cross-regenerative 12.25-ton ovens with a capacity of 1100-1150 tons of coal per day, and is complete for the recovery of gas, tar,  $\text{NH}_3$  and benzene. It produces 6 million cu. ft. of city gas per day, 9 gals. tar, 25 lbs.  $(\text{NH}_4)_2\text{SO}_4$  and 3 gals. benzene motor fuel per ton of coal. The plant shows in a practical way that bulk carbonization is a method of operation which must occupy the attention of the gas industry.  
J. L. WILEY.

Chester producer fired by-product coke ovens. J. D. SHATTUCK. *Gas Age* 43, 7-10(1919).—A description of a Semet-Solvay installation originally designed to carbonize 300 tons of coal per day for production of city gas and recovery of by-products. It consists of 40 ovens built in 1903-4,  $\text{NH}_3$ , tar, light oil, cyanogen and naphthalene recovery plants, and 4 Taylor gas producers which furnish gas for heating the ovens, increasing the city gas supply, and keeping up the steam requirements. A very efficient operation is suggested in thus combining the functions of both coke-oven plant and gas plant under one installation.  
J. L. WILEY.

Republic by-product coke plant at Youngstown. ANON. *Gas Age* 43, 13-5 (1919).—An installation of 143 Koppers 13.25-ton ovens with complete by-product recovery plant. It produces gas and coke for the plant of the Republic Iron & Steel Co. It carbouizes 2800 tons of coal per day, with a production of 1900 tons furnace coke, 140 tons coke breeze, 61,000 lbs.  $(\text{NH}_4)_2\text{SO}_4$ , 25,200 gals. tar, 16 million cu. ft. surplus gas, and 8,000 gals. benzene.  
J. L. WILEY.

Preparation of domestic coke. A. H. HARRIS, JR. *Gas Age* 43, 17-8(1919).—A detailed description of the prepn. of domestic coke from by-product ovens as carried out at the plant of the Coal Products Mfg. Co., Joliet, Ill.  
J. L. WILEY.

Insulation for by-product coke ovens. P. A. BOECK. *Gas Age* 43, 24-6(1919).—A discussion of the methods used in insulating the various parts of a by-product oven by means of Sil-O-Cel insulating brick and powder. This material is made from natural celite rock; it will withstand a temp. of 1800° F. without shrinkage and has a melting point of 2930° F. It is stated that Sil-O-Cel insulation will reduce heat losses by radiation by 60-75%.

---

Composite fuel. WM. CLAYTON. Can. 188,318, Jan. 21, 1919. The fuel contains coal screenings 20, charcoal or peat 10, loam 25, clay 10, sawdust 15, sand 5, lime 2, linseed or crude oil 13.

Gas manufacture. J. T. KEY. Brit. 120,139, Dec. 14, 1917. Cannel or other coal is coked in retorts which are built up in sections and are arranged in series which deliver their gaseous products into mains provided with sets of grids, the openings of

alternate grids being arranged in rows which are at right angles to each other or are otherwise arranged to cause the gases to take tortuous paths. Superheated steam is introduced into the retorts from mains by pipes, at the end of the period of ordinary distn. by heat, and the action of this on the coke, and the subsequent mixing and vaporization of the products in the main is adapted to yield a high vol. of gas per ton of coal. Valves and dampers are employed so that some of the ovens may be charged while others are being worked; and steam is admitted to some of the ovens while the others are giving off gas without the aid of the steam.

**Gas manufacture.** S. N. WELLINGTON. Brit. 120,223, July 30, 1917. Gas from the low-temp. distn. of coal or other carbonaceous material is reheated by means of producer gas in a heat-exchanger on the way from the tar-separator to the  $\text{NH}_3$  saturator. The heat-exchanging app. may take any suitable form.

**Desulfurizing gases, etc.** H. W. HEMINGWAY. Brit. 117,387, Nov. 21, 1917. In desulfurizing coal gas, etc., by means of  $\text{FeCO}_3$ , as described in 12,093, 1901, the  $\text{FeCO}_3$  is recovered by converting the  $\text{FeS}$  obtained into  $\text{FeSO}_4$  and then treating the effluent or "sweet" liquor with the  $\text{FeSO}_4$ . The  $\text{FeCO}_3$  pptd. is recovered for use in the first stage.

**Horizontal coking ovens.** O. PIETTE. Can. 188,587, Jan. 21, 1919. Structural features.

## 22. PETROLEUM, ASPHALT AND WOOD PRODUCTS.

F. M. ROGERS.

**A new British oil industry.** E. H. C. CRAIG, F. M. PERKIN, A. G. V. BERRY AND A. E. DUNSTAN. *J. Inst. Petroleum Tech.* 4, 110-57(1918).—See C. A. 12, 1119.

E. H.

**Borneo petroleum and its uses.** A. DUBOSC. *Caoutchouc et gutta-percha* 15, 9550-2(1918); cf. C. A. 12, 2711.

JOHN B. TUTTLE.

**The oil-bearing lands of Morocco.** M. MOUSSU. *Bull. soc. encour. ind. nat.* 130, 248-54(1918).—The oil is found in the dried beds of small rivers. During the rainy season the oil is carried in the small streams in an emulsified condition. The oil is heavy, brown, almost black. The sp. gr. ranges from 0.900 to 0.906. The distn. begins at 90°, 4% off at 150°, 20% at 200°, 72% at 225°. The gravity of the distillate ranges from 0.800 to 0.830.

O. E. BRANSKY.

**The relation between viscosity and the chemical constitution of lubricating oils.** A. E. DUNSTAN AND F. B. THOLE. *J. Inst. Petroleum Tech.* 4, 191-228(1918).—See C. A. 12, 1596.

E. H.

**Lubricating oils.** DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH, LONDON. *J. Ind. Eng. Chem.* 11, 155(1919).—A memorandum issued by this dept., dealing with the subject of cutting lubricants and cooling liquids, states that the mineral oils which are best suited for the first named purpose, either by themselves or in combination with oils of animal or vegetable origin, are those of pale color and low viscosity ranging from 100 to 200 sec., Redwood Standard, at a temp. of 200° F. For high-speed conditions oils of lower viscosity can be used and similarly oils of higher viscosity are suitable for low-speed work. Taking the animal oils, used either alone or in combination with one another, it is found that prime lard oil is practically free from acid while tinged lard oil contains a percentage as high as 15 in some cases. The tinged oil is less costly in the first place but is more inclined to gum under severe conditions. Since lard oil congeals in cold weather it should be mixed with good low-cooled mineral oil for winter use.

E. J. C.

**Present status of oil shales.** ANON. *Chem. Met. Eng.* 20, 28-31(1919).—Besides the huge deposits of oil shales occurring in Utah, Wyoming, Colorado, Nevada and small areas all over the Rocky Mountains, there are numerous small deposits of asphaltic sandstones distributed over the Western plateau. In spite of the many processes and companies devised and organized for getting the oil from the shales, no oil has been produced. The Scottish retort combined with the labor-saving devices of the modern by-product coke oven is recommended as the best installation for distg. the oil shales. The distillates are full of highly unsatd. compds., containing considerable N and S. The acid-treating losses are very heavy. The amt. of recoverable N is small. The asphaltic sandstones have been extd. with solvents, such as gasoline, and a heavy residuum of about 10° Bé. resembling Mexican and California crude has been obtained.

O. E. BRANSKY.

---

**Separation of mineral oil from saponifiable oil (PRATHER) 27.**

---

**Distilling petroleum.** C. B. FORWARD. *Brit.* 117,372, Oct. 27, 1917. In distg. petroleum to obtain motor fuel oil, the petroleum is gradually heated to 400° F. or higher by passage through long coils exposed to superheated steam, and is then mixed with superheated steam in an atomizer or injector and is delivered into a separator in which the motor fuel oil is vaporized. Superheated steam is obtained from a high-pressure generator fitted with superheating coils and is divided into two parts, one passing through a pipe to the atomizer, and the other passing through heaters in counter-current to the oil flowing through the long coils specified. The steam leaving the last heater in the series is used for heating and power purposes. A pressure of 100-200 lb. per sq. in., and a temp. of 400-600° F. or higher, are maintained in the separator. The vapors leaving the separator are led to a clarifying column containing baffles, and thence through a pressure-reducing valve to a condenser.

**Cracking hydrocarbons.** R. B. DAY. *Brit.* 120,230, Sept. 27, 1917. Hydrocarbon oils, of a relatively low b. p., such as gasoline, benzene, toluene, etc., are obtained from heavier oils of a high b. p. by heating the heavy oil, mixing it in predetd. proportions with heated H<sub>2</sub>O by means of sets of H<sub>2</sub>O and oil pumps, spraying the mixt. into a heating chamber or tube heated to a temp. of from 600 to 2000° F., and subjecting the mixt. to the action of a catalytic agent consisting of an alloy of Ni, Cr and steel placed at the outlet end of the chamber or tubes, the mixt. being then passed through an oil-cooled primary condenser for removing the uncracked oils and a water-cooled secondary condenser for condensing the hydrocarbons of lower b. p. Each set of pumps delivers into a common chamber and the driving-means of the H<sub>2</sub>O pumps is made adjustable. The pressure in the heating chambers or tubes may vary from atm. to 300 lb. per sq. in. A suitable form of app. is specified, with details of operation.

---

### 23. CELLULOSE AND PAPER.

---

A. D. LITTLE.

**Stabilization of celluloid.** A. COLASSI. *Caoutchouc et gutta-percha* 15, 9604-5 (1918).—During the nitration of cotton for celluloid, higher nitrates are formed insol. in the usual solvents. These are not removed by washing with cold water. C. proposes to wash the nitrated cotton with warm water in a Hollander, during which the higher nitrates are powdered and washed out. This is all that is necessary for stabilization.

JOHN B. TUTTLE.

**Notes on the analysis of celluloid.** A. HERVE. *Caoutchouc et gutta-percha* 15, 9601-4(1918).—H. has adapted a modification of Raoult's f.-p. app. for the detn.

of camphor in celluloid. A 2-5 g. sample is cut into small pieces, placed in a 500-cc. flask with 200 cc.  $H_2O$  and 2-3.5 g.  $KOH$ , and the flask is connected to a condenser. The nitrocellulose is dissolved, and the camphor distd. Most of the camphor collects in the condenser. The aq. distillate is washed with 2 portions of  $C_6H_6$  (5 cc. each). These are collected and used to wash out the condenser, which is then washed with 5 further portions of 5 cc.  $C_6H_6$ . The  $C_6H_6$  soln. is dehydrated with anhydrous  $CuSO_4$ , filtered and made up to 50 cc. at  $20^\circ$ . The app. is constructed as follows: A tube containing the  $C_6H_6$  soln. is placed in a closed tube containing  $CS_2$ . The outer tube has a pipe leading to the bottom of the  $CS_2$  and ending in a ring. The pipe is pierced with small holes, through which air is blown. A second pipe provides an exit of the air and  $CS_2$  fumes. Evapn. caused by the current of air lowers the temp. sufficiently for the detn. The lowering of the f. p. of the  $C_6H_6$  is noted with a Beckmann thermometer and the % of camphor calcd. A table of values is given. Results give 28.2 and 27.9% against a calcd. value of 28.55%.

JOHN B. TUTTLE.

**Cello yarn—the latest cellulose yarn.** *Svensk Papperstidning* 1918, No. 22, 523.—New inventions for the manuf. of cellulose yarn are constantly being made in Germany. The latest invention is "Cello yarn." This is considered equal to "Stapel-faser" without being identical with it. It is flexible, strong and washable. The methods of manuf. have been worked out by Adolf Kube Co., G. m. b. H., of Dresden.

G. HALLBERG.

**South African grasses for paper making.** ANON. *Bull. Imp. Inst.* 16, II, 127-34 (1918).—A sample of Johnson grass (*Sorghum halepense*) gave on analysis moisture 10.3%, ash 7.4, cellulose 52.5 (the last two are expressed on the dry grass). The grass was treated with caustic and gave 45-50% dry pulp which yielded a tough parchment-like paper. A sample of thatching grass (*Andropogon buechananii*) contained moisture 10.1%, ash 6.3, cellulose 53.8% (with the last two expressed on the dry grass). Boiling with 10-20% caustic gave 46-52% pulp which furnished an opaque paper of good strength and quality. Specimens of *Andropogon oregeamus* (tamboukie grass) contained moisture 9.1%, ash 4.5, cellulose 47.4%. Treatment with soda yielded 40-50% pulp, which could readily be bleached and used for the production of white paper of good quality. A sample of *Andropogon hirtiflorus* contained moisture 8.7%, ash 3.8, cellulose 55.8%. Boiling with soda solns. of varying concns. yielded 50-54% pulp. This pulp yielded paper that was weak but could be bleached to a good color.

R. L. SIBLEY.

**Production of pulp in Japanese Sachalin.** *Svensk Papperstidning* 1918, No. 22, 523.—The manuf. of pulp in Karafuto (Japanese Sachalin) is constantly growing. The yearly production is expected shortly to be 100,000 tons. It is considered that the Japanese paper mills will be very soon altogether independent of the import of foreign pulp.

G. HALLBERG.

**Manufacture of paper-pulp from dead leaves.** KAREN BRAMSON. *Compt. rend.* 166, 853-4 (1918).—See *C. A.* 12, 2053.

R. B. ROE.

**Color reaction of mechanical wood pulp or of the incrusting substances of wood with phenylhydrazine hydrochloride.** S. JENTSCH. *Z. angew. Chem.* 31, 72 (1918); *J. Soc. Chem. Ind.* 37, 365-6A.—See *C. A.* 12, 2052.

R. B. ROE.

**Chemical investigation of black liquor.** E. J. HOFFMAN. *Paper* 23, No. 19, 11-3 (1919).—A 10-l. sample of concd. black liquor from a soda-pulp mill on distn., yielded 850 cc. of aq. distillate and 710 cc. of tars, the latter corresponding to 100 kg. per ton of pulp. The tar distillate on fractional distn. yielded 73% up to  $280^\circ$ . The fraction up to  $100^\circ$  amtd. to nearly 20% of the tar, and consisted of approx. 6% oil and 14% water. The oily portion contained small amts. of aromatic hydrocarbons. Of the portion distg. from  $100$  to  $280^\circ$ , approx. 70%, or 37% of the original tar, was sol.

in dil. NaOH. The fraction from 100° to 280° was further distd. and found to contain approx. 10% of phenolic compds. As a result of the investigation it seems impracticable to attempt to utilize this tar or any of its fractions as a source of raw materials for explosives.

R. B. ROE.

---

Waste pulp from New Zealand hemp (ANON.) 25.

---

Cellulose and fodder from wood and the like. J. KÖNIG. *Holl.* 2,504, Oct. 1, 1918. After a suitable acid or alk. treatment, the wood is treated with sulfite.

Coated paper. H. R. RAFSKY. *Brit.* 117,414, Feb. 23, 1918. Paper is coated with "lime mud," a material obtained as a ppt. in the causticizing, by means of lime, of the  $\text{Na}_2\text{CO}_3$  obtained from the waste liquors produced in the wood pulp, esparto pulp, and other industries. The "lime mud," which may be reduced by grinding, is mixed with an adhesive such as casein and a small amt. of alkali.

## 24. EXPLOSIVES AND EXPLOSIONS.

C. E. MUNROE.

Nitration of cellulose and determination of the nitrogen content in cellulose nitrates. A. HERVÉ. *Mon. Sci.* 8, 241-5 (1918); cf. *C. A.* 13, 186.—The investigation had for its object the verification of Lunge's work (*Mon. Sci.*, May-June, 1902) as applied to particular cases, viz., the effect on the N content of variations in (1) the per cent. of  $\text{H}_2\text{O}$ , and (2) of  $\text{HNO}_3$  in the nitration mixt. All expts. were conducted at 25°, the duration of nitration was 25 mins., and the ratio of cellulose to the mixed acids was 1:100. The individual results are presented in tabular form and show that starting with  $\text{H}_2\text{SO}_4$  66.97,  $\text{HNO}_3$  14.91 and  $\text{H}_2\text{O}$  18.12, and increasing the  $\text{H}_2\text{O}$  in 5 successive steps to 20.23 the  $\text{H}_2\text{O}$  in the spent acids rose steadily from 18.44 to 20.52 and the N content of the product fell steadily from 11.16 to 10.08. Also starting with  $\text{H}_2\text{SO}_4$  66.85,  $\text{HNO}_3$  14.55 and  $\text{H}_2\text{O}$  18.66 and increasing the  $\text{HNO}_3$  in 6 successive steps to 18.84, the N content of the product rose steadily from 10.81 to 11.14. In both series the  $\text{H}_2\text{SO}_4$  was the second variable in the nitration mixts.,  $\text{HNO}_3$  remaining practically const. in the 1st series and  $\text{H}_2\text{O}$  in the 2nd. H. describes the methods employed for regenerating the spent acids for re-use and dwells upon the importance of proving, by analysis, that the mixt. is perfectly homogeneous. Examples of acid mixts. tested at various stages of blowing are given showing as much as 2.3% difference on the  $\text{HNO}_3$  and 2% on the  $\text{H}_2\text{O}$  which, if used in nitration, would lead to a difference of 1.19% in the N contents. Detailed descriptions of the Lunge and the Crum methods of detg. N used are given.

CHARLES E. MUNROE.

Powders and explosives. GEORGES VIE. *Rev. prod. chim.* 21, 273-4, 292-3 (1918).—A popular review consisting mostly of material which has been repeatedly published. A novelty is a new classification entitled "Explosives of juxtaposition" to designate brisant explosives composed of substances which separately are completely inert. Favier's explosives are cited as an example. A table is given of the wt. of powder necessary to propel projectiles of various sizes and as charges for mines and torpedoes. Also the wts. of  $\text{HNO}_3$  required in the manuf. of one metric ton of the following: Melinite 1820 kg., T. N. T. 1760 kg., nitroglycerin 1180 kg. and nitrocellulose (for powder) 1000 kg.

CHARLES E. MUNROE.

Standardization of mining methods. IV. Explosives. CHARLES MITKE. *Eng. Min. J.* 106, 982-7 (1918).—A description, with illustrations, of methods for handling and storage of explosives, on the surface and underground, loading and blasting, with the order of procedure to insure safety. The machines shown for cutting running fuse

and for prepg. cartridges of clay stemming and the fuse cans for transporting capped fuse to the mine are of special value.

CHARLES E. MUNROE.

**The dangers of explosion with inflammable liquids and vapors.** W. PAYMAN. *J. Soc. Chem. Ind.* 37, 406-82 (1918).—Danger of explosion from ignition of mixts. of inflammable vapors and air exists in many industrial operations such as: (A) Processes in which volatile combustible liquids are used for crystn., pptn., or solvents, or when being nitrated or sulfonated. (B) When being vaporized from finished products in drying stoves or rooms. (C) During storage and transfer. Important criteria for judging the liability of a given liquid to produce dangerous conditions are: (1) Its volatility. (2) The range of explosion of mixts. of its vapor with air. (3) The speed of propagation of flame in these mixts. (4) Their ease of ignition. Attention must be given to the possibility of ignition of such mixts. by mechanical means such as by sparks, caused by grinding of ill-fitting parts, or by over-heated bearings. Inert gases should be substituted for compressed air in moving these liquids. Their evapn. during storage may be retarded by reducing the area of exposed surface. The following table of data is presented:

| Substance.             | Lower limit.<br>Per cent. | Corresponding<br>temp., ° C. | Upper limit.<br>Per cent. | Corresponding<br>temp., ° C. |
|------------------------|---------------------------|------------------------------|---------------------------|------------------------------|
| Benzene.....           | 1.4                       | —5                           | 4.7                       | 5                            |
| Toluene.....           | 1.4                       | 7                            | 4.7                       | 30                           |
| Ethyl alcohol.....     | 4.0                       | 15                           | 13.6                      | 35                           |
| Methyl alcohol.....    | 7.8                       | 13                           | 18.0                      | 26                           |
| Ethyl ether.....       | 1.8                       | Below — 30                   | 5.2                       | —28                          |
| Acetone.....           | 2.35                      | Below 20                     | 8.5                       | Below 20                     |

| Petroleum benzine..... | 1.1                       | ...                          | 3.8                       | ...                          |
| Gasoline.....          | 1.5                       | ...                          | 5.3                       | ...                          |
| Pentane.....           | 1.35                      | Below 0                      | 4.50                      | Below 0                      |

The limits of inflammability are expressed in percentage by vol., and refer to downward propagation of flame. The "Limit Temps." have been calcd. from the vapor pressures in Landolt-Börnstein. Each topic is discussed fully and much literature is cited.

CHARLES E. MUNROE.

Chemical investigation of black liquor (HOFFMAN) 23.

## 25. DYES AND TEXTILE CHEMISTRY.

L. A. OLNEY.

**Dyes and the development of British chemical industry.** ASSOCIATION OF BRITISH CHEMICAL MANUFACTURERS. *Nature* 102, 272-3 (1918).—A memorandum presented to the President of the Board of Trade setting forth the views of the executive council of the association on the present situation in that section of chem. industry which is directly concerned with the production of dyes.

W. H. ROSS.

**Waste pulp from New Zealand hemp.** ANON. *Bull. Imp. Inst.* 16, 134-8 (1918).—A large amt. of waste pulp is obtained from the leaves of the New Zealand hemp plant (*Phormium tenax*). Two samples of this pulp were taken; one was sun-dried before placing in sacks, the second was rotted for 2 mos., sun-dried, then placed in sacks. These samples were examd. as to their value for the manuf. of paper pulp. Analysis gave: (sun-dried) moisture 8.3%, cellulose in dry pulp 31.8%; (rotted sample), moisture 8.9%, cellulose 37.4%. In both cases the cellulose was of poor quality and of no value for paper making. The pulps were investigated to ascertain their fertilizer value

and the possibility of using them as sources of potash salts. Analyses of the materials are given and the figures are compared with an analysis of stable manure. The results show that the pulp would have considerable fertilizer value on account of the N (1%),  $K_2O$  (2.93 and 3.93%) and  $H_3PO_4$  (0.4% as  $P_2O_5$ ). The rotted material contained the higher % of  $K_2O$ , while the N and  $P_2O_5$  did not vary much. Wt. for wt. the dried materials contain twice as much N, the same amt. of  $P_2O_5$ , and 5-6 times the amt. of  $K_2O$  as stable manure. The heating value of the sun-dried pulp is about 45% that of good steam coal.

R. L. SIBLEY.

Nature of cyclic quinoneimide dyes (KEHRMANN) 10. The linear phenonaphth-acridonequinone and quinacridonequinone (LESNIANSKI) 10. Synthesis of amino-flavones, of flavoneazo- $\beta$ -naphthol dyes and of other flavone derivatives (BOGERT, MARCUS) 10. Industrial efforts of France during the war (MAOUSSA) 18. Isolation of dyes with picric acid and dichloropicric acid (WILLSTÄTTER, SCHUDEL) 10. Tintometry (SCHELL) 2.

Dyes from oxylignin or oxylignone. E. ØMAN. Norw. 28,913, July 8, 1918. Oxylignin or oxylignone is converted into nitroso compds. by reaction with  $HNO_3$  or substances yielding it, such as nitrite and acid.

Dyes from lignin- or lignonesulfonic acid or salts thereof. E. ØMAN. Norw. 28,934, July 15, 1918. The initial materials are converted into nitroso compds. by treatment with  $HNO_3$ .

Obtaining textile fibers. A. F. W. BRUMMER. Brit. 120,199, Aug. 21, 1918. Fibers are obtained from grass, reed, rushes, straw, stalk, bark, and like vegetable materials by boiling with an alkali sulfide, such as  $Na_2S$  or an alk.-earth sulfide or a mixt. of such sulfides, and subsequently treating with hot alum soln., or with a soln. of  $Na_2S_2O_3$  to which a little  $H_2SO_4$  has been added. The product is washed and dried.

## 26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN.

The determination of volatile "thinners" in oil varnishes. A. DE WARLE. *Analyst* 43, 408(1918).—de W. and Smith in a previous paper (*C. A.* 11, 2547) recommended the use of  $Me_2CO$  for removal of last traces of  $H_2O$  from the non-volatile residues obtained in the steam distn. of oil varnishes. Highly polymerized oils, however, present in some varnishes, are not sol. in  $Me_2CO$ ; so that residual  $H_2O$  is removed with difficulty. This  $H_2O$  can be completely removed by boiling out the residue twice, using about 10 cc. each time, with a mixt. of 3 parts benzene and one part alc. F. A. WERTZ.

Paint. J. C. BENNECHER. U. S. 1,287,836, Dec. 17. A paint suitable for use on wood or metals is prepd. by mixing 75 kg. of dry color with sufficient linseed oil and petroleum to form a paste, forming another pasty mixt. of  $Ca(OH)_2$  and  $H_2O$ , aggregating the 2 mixts. and mixing with additional oil and petroleum, then adding a soln. of yellow soap 10 kg. in  $H_2O$ , and finally adding 16 kg. resin melted in 10 l. boiled linseed oil.

Paint. KOPPERS CO. Can. 188,272, Jan. 14, 1919. A paint having as its essential constituent a colloidal soln. of coal-tar pitch in solvent naphtha will readily dry to form a smooth, glossy surface. The coal-tar pitch has a relatively low content of free C.

**Pigments.** NEW JERSEY ZINC CO. Brit. 120,194, Apr. 12, 1918. Zn-Pb pigments are obtained by roasting oxidized ores of Zn and Pb so as to volatilize the Zn and Pb under oxidizing and sulfatizing conditions, in order to sulfatize the Pb without materially effecting the ZnO. A suitable furnace is specified.

## 27. FATS, FATTY OILS AND SOAPS.

R. SCHERUBEL.

**Oils in Germany.** ANON. *Int. Rev. Sci. Practice Agr.* 8, 1128(1917); *Bull. Imp. Inst.* 16, 254(1918).—Owing to the shortage of oils in Germany attention has been turned to a number of seeds which can be obtained from indigenous plants or plants grown there. Among those exptd. with are rape, sunflowers, poppies, beechnuts, walnuts, horse-chestnut, lime-seed, spruce seed. It appears that beechnuts are to be used for human consumption, while horse-chestnuts and acorns are to be reserved for cattle food.

R. L. SIBLEY.

**Tomato seeds.** ANON. *Bull. Imp. Inst.* 16, 254(1918).—Tomato seeds and skins obtained as waste products of the canning industry are dried and the seed is sepd. from skin by sifting. The seeds then yield 22% of an oil of pale yellow color and a bland nut-like taste and odor. The residual cake has given satisfactory results in feeding expts.

R. L. SIBLEY.

**Marine animal oils from the Antarctic.** ANON. *Bull. Imp. Inst.* 16, 140-5(1918).—Five samples of sea-leopard oil upon analysis gave sp. gr. 0.924, acid value 0.3 to 1.1, sapon. value 193.7 to 195.1, iodine value 119.7 to 127.1, insol. fatty acids 94.6%, unsaponifiable matter 0.5%, sol. volatile acids 0.65%, insol. volatile acids 1.05%, solidifying point 3-11.9°. Seven samples of seal oil gave the following results: sp. gr. 0.924-0.931, saponification value 192 to 201.5, acid value 0.8 to 4.2, iodine value 122.1 to 147.8, insol. fatty acids 94.3%, unsaponifiable matter 0.9%, sol. volatile acids 0.6%, insol. volatile acids 0.9%, solidifying point of fatty acids 16° to 19°. Penguin oil gave d. 15° 0.932, acid value 2.3, sapon. value 1975, iodine value 126.7, insol. fatty acids 94.7%, unsaponifiable matter 0.5%, sol. volatile acids 0.65%, insol. volatile acids 1.0, solidifying point fatty acids 31.4°. The sea leopard oil and Weddell seal oil are very similar in character, although there appears to be a larger amt. of stearin in the latter. All the oils are suitable for soap making and yielded a considerable quantity of glycerol. The oils could be used for any purposes to which commercial seal and whale oils are put.

R. L. SIBLEY.

**Note on the separation of mineral oil from saponifiable oil.** P. W. PRATHER. *Chem. Analyst* 26, 19(1918).—In sepg. mineral oils from saponifiable oils, emulsions are frequently encountered after the soap soln. is shaken with Et<sub>2</sub>O in a sepg. funnel. The emulsion can be destroyed and sharp sepn. obtained by applying the hose of a good suction pump to the mouth of the funnel.

H. M. LANCASTER.

**Sunflower (KRAUS) 15. The chemical constitution of squalene (KUBOTA) 10.**

**Separating liquid and solid constituents from fats.** W. P. SCHUCK. U. S. 1,288,228, Dec. 17. In sepg. liquid and solid constituents from oils, e. g., coconut oil, about 5% of flax or similar fiber is mixed with the oil, this mixt. is molded into cakes, and the latter are pressed while enclosed in filter cloths at a temp. slightly below the m. p. of the oil. After expressing the normally liquid constituents, the residue is melted and sepd. from the fiber.

**Hydrogenated oil mixture suitable for use in foods, lubricants or abrasives.** C. ELLIS. U. S. reissue 14,568, Dec. 17. See original pat. 1,276,509; C. A. 12, 2139.

**Hydrogenated oil mixture for making sound records.** C. ELLIS. U. S. reissue 14,569, Dec. 17. See original pat. 1,276,508; C. A. 12, 2139.

**Hydrogenated oil mixture for making sound records.** C. ELLIS. U. S. reissue 14,570, Dec. 17. See original pat. 1,276,507; C. A. 12, 2139.

**Extracting oils.** A. M. WINTERS. Brit. 120,156, Jan. 24, 1918. Oil-bearing material such as offal or crushed seeds, beans, nuts, etc., passes from a hopper through one or more extg. chambers provided with conveying worms wherein it is treated with solvents, such as benzine, supplied through the perforated shafts of the worms or through perforation in the upper parts of the chambers covered by a jacket. The solvent is supplied to the first two of the chambers but not to the third. The solvent passes from the chamber through removable sieves and by pipes into a chamber containing inclined baffles and sieves and heated by steam from a pipe. The solvent vapors are led to a condenser and the condensed solvent is returned to the extn. chambers,  $H_2O$  being sepd. in a gravity separator. The oil is removed by a pipe. The material, after passing through the extn. chambers, falls down a chute into a chamber heated by steam from a pipe and containing inclined grids or sieves. The solvent is removed as vapor and is returned to the extn. chambers by way of condensers and water-separator. Air, laden with solvent vapors from various parts of the app., is passed through a washer to sep. the solvent.

**Cleansing compositions.** G. A. PAULIN. Brit. 120,195, June 26, 1918. A cleansing compn. is prepd. by mixing powdered casein with a satd. soln. of  $Na_2CO_3$  and mixing the product with a resin soap prepd. by saponifying com. resin with  $NaOH$ . The compn. may be scented with oil of thyme, oil of lemon thyme, essence of mirbane, etc.

---

## 28. SUGAR, STARCH AND GUMS.

---

A. HUGH BRYAN.

Some notes on the clarification of the juice from frozen or sour cane. C. E. COATES. *Louisiana Planter* 62, 40-1(1919).—Freezing may affect the compn. of juice of standing cane in 3 ways: (1) Fiber may be partly converted into sol. gums; this effect can be remedied to some extent by adding dil.  $H_3PO_4$  or  $H_2SO_4$  in the pan. (2) Dextran and similar gums may be formed; this can be detected by polarizing in alc. soln., and it is stopped by thorough disinfection of tanks and machinery. (3) Acetic fermentation may set in; excess acidity in juice should be neutralized with  $Na_2CO_3$ . Crystn. in sirups from frozen cane can be induced by seeding with sugar crystals or powdered sugar.

F. W. ZERBAN.

Why not shredders in Louisiana? K. R. MORGAN. *Louisiana Planter* 62, 39 (1919).—Use of the Searby shredder has raised the extn. in a Hawaiian factory to 97.5% sucrose in cane, and over. Its use is recommended for Louisiana.

F. W. ZERBAN.

Some observations on the rust disease of beet-foilage. W. BARTOS. *Blätter für Zuckerrübenbau* 24, 152(1917); *Biedermanns Zentr.* 47, 263-5(1918).—This rust disease is inheritable. It is customarily disregarded by the farmer as it ordinarily appears only on the fully mature beet plant. B. found that beets of the same variety taken from the same field contained 22.02% sugar when their foliage was entirely free from rust and 21.48% when attacked by rust. These were resp. planted as seed beets on adjacent plots. The sugar content of the crop from the infected seed was 1.5% less than that of the healthy crop and the yield of beets was less for the seed used.

ALBERT R. MERR.

The improvement of the indigenous methods of gur and sugar making in the United Province, B. E. I. WILLIAM HULME AND R. P. SANGHI. *Louisiana Planter* 62, 42-5(1919).—Description of native methods and those used in an exptl. factory of more modern design.  
F. W. ZERBAN.

Method for the preparation of soluble starch. JAMES CRAIG SMALL. *J. Am. Chem. Soc.* 41, 113-20(1919).—Weighed amts. of raw potato starch were boiled under a reflux for measured time intervals in 95% alc. containing varying amts. of concd. HCl and then either quickly filtered and washed free of acid with distd.  $H_2O$ , or treated with the calcd. amt. of  $NaHCO_3$  to neutralize the HCl and washed with alc. In the samples so obtained quant. detns. were made of the total and sol. starch (see following abstr.) and qual. tests were also made for unchanged starch, dextrans and lower reducing carbohydrates. From these preliminary expts. it would seem that for a 20% suspension of starch in alc. 0.75 cc. of HCl (d. 1.19) per 100 cc. effects complete conversion of the starch in 10 min. and yields a product in which no dextrans or reducing carbohydrates can be identified. Another series of expts. in which only the amt. of HCl was varied confirmed the above result.  
CHAS. A. ROUILLER.

Quantitative determination of soluble starch in the presence of starch and its hydrolytic cleavage products. JAMES CRAIG SMALL. *J. Am. Chem. Soc.* 41, 107-12 (1919).—The iodide of sol. starch is readily pptd. from its solns. in the presence of dextrans and lower carbohydrates by an equal vol. of satd.  $(NH_4)_2SO_4$  and this ppt. can be washed free from the other carbohydrates by half-satd.  $(NH_4)_2SO_4$ ; on heating the ppt. in  $H_2O$  suspension the I is driven off and the sol. starch can then be hydrolyzed by acids and estimated by the usual methods for detg. dextrose. Amylodextrin also comes down in half-satd.  $(NH_4)_2SO_4$  in the presence of excess of I but can be washed out if no I is added to the successive wash liquids and it can thus be also detd., either directly or indirectly.  
CHAS. A. ROUILLER.

#### Determination of dextrose with hypiodite (WILLSTÄTTER, SCHUDEL) 7.

Glycerol from fermentation of sugars. J. R. ROFF, JR. U. S. 1,288,398, Dec. 17. "Black strap" molasses, or similar material, dild. until it contains about 11% total sugars, is fermented so as to obtain a 20% conversion of the sugars into glycerol. During the fermentation the alkalinity of the material is maintained, by successive additions of  $Na_2CO_3$ , just short of the degree which would inhibit further fermentation. Various yeasts, both *Cerevisiae* and *Ellipsoideus*, may be used in carrying on the process but the California wine yeast of the *Ellipsoideus*, variety Steinberg, gives best results. The yeast is preferably first cultivated in sterile grape juice containing dextrose and nutrient salts and, during its cultivation,  $Na_2CO_3$  or  $K_2CO_3$  is added. The yeast is then added to the molasses or to a mixt. of a wort prepd. from malt sprouts and dextrose and fermentation of the latter carried on in alk. soln. to form glycerol. The pat. is dedicated to the public for free use without payment of any royalty.

Glucose. F. B. LA FORGE. U. S. 1,288,429, Dec. 17. In making glucose from corn cobs, the latter are subjected to hydrolysis with dil.  $H_2SO_4$ , the undissolved solid material is washed free from acids and other sol. substances, dried, finely ground, mixed with about an equal weight of 75%  $H_2SO_4$ , allowed to stand for several hrs., and heated with a large quantity of  $H_2O$  until hydrolysis is complete. The soln. is then filtered, neutralized with  $Ca(OH)_2$ , the ppt. is filtered out and the soln. is concd. until glucose seps. in crystd. form.

## 29. LEATHER AND GLUE.

ALLEN ROGERS.

Recent developments in leather chemistry. HENRY R. PROCTER. *J. Roy. Soc. Arts* 66, 747-53, 776-81; *J. Am. Leather Chem. Assoc.* 13, 582-95 (1918); 14, 30-41 (1919).—A lecture delivered before the Royal Society of Arts, May 13, 1918, in which some of the important processes preliminary to tanning and the improvements made in them are described. The anatomical structure and the chemistry of skin are briefly discussed while the various methods of unhairing, deliming, bating, puering, and drenching are treated in detail. All of the above processes involve the swelling and falling of hide fibers and because of this the author has, for the last 20 years, devoted much study to the process of pickling, which process "involves both swelling and falling, and will in itself convert skin into a sort of leather, so that manifestly its full explanation would throw a good deal of light on the whole theory of tanning." In the discussion of the author's expts. and results of this study the theory of swelling is given.

R. W. FREY.

Theory of leather formation. V. W. FAHRION. *Collegium* 1918, 173-8, 213-4; *J. Soc. Leather Trades Chem.* 2, 304-5 (1918).—Polemical against Moeller's criticism of the chem. theory of tanning. Oryng (*Kolloid-Zig.* 22, 149 (1918)) says all adsorption compds. are being proved to be chem. compds. If so, discussion as to whether tanning is chem. or phys. will vanish. There is no analogy between the behavior of formaldehyde with collagen and with albumin, since collagen is an albuminoid, not an albumin. Acetaldehyde tans very little, and aromatic aldehydes scarcely at all because  $\text{CH}_3$  must be directly connected to aldehyde O in a tanning substance. The reaction of the polymerization products of formaldehyde on collagen can be explained by catalysis without Moeller's peptization theory. Moeller's expts. with acetone and with *o*-nitrobenzaldehyde are not conclusive. Even the polymers of formaldehyde are chem. compds. and such an addition compd. can be assumed in case of the collagen-acetone system. Moeller's expts. in quinone tannage do not offer convincing proof. The decompn. products of quinone and  $\text{H}_2\text{O}$  are shown to be unnecessary for tanning, and hence Moeller's peptization theory is unnecessary and incorrect. W. B. J.

Causes of brittle grains. ANON. *Halle aux cuirs*, Oct. 27, 1918; *J. Soc. Leather Trades Chem.* 2, 307.—When leather is too rapidly dried out of either mineral or vegetable tan, moisture from the interior carries and deposits non-tans just under the surface of the grain and upon it. To prevent this, the surface may be lightly, but especially in sole leather not too heavily oiled. W. B. J.

The quinone tannage. I. W. MOELLER. *Collegium* 1918, 71-8, 93-105; *J. Soc. Leather Trades Chem.* 2, 190-1, 243-4.—Quinone has been obtained from many materials containing tannins by oxidation. There is much evidence indicating that tannins have a quinone character. Quebracho, phlobaphenes when distd. with zinc dust give anthracene, Nierenstein (*Ber.* 1907) thinks that this is from rufgallic acid, which is a hexahydroxyanthraquinone. Powarin found hydroxyanthraquinone in willow bark tannin. Korner found that by passing air into an aq. soln. of quebracho tannin phlobaphenes were obtained which differed very little in their chem. compn. from the tannin. The phlobaphenes always present in the quebracho soln. only sep. out because of the oxidation of the peptizer to dark colored humins. The amorphous brown compds. obtained by oxidizing or heating pyrogallol (Procter, *L. I. L. B.* 115, 120) are related to, if not identical with, those products obtained by oxidizing quinone in aq. soln., which give rise to the tanning effect of quinone. By disturbing the peptizer through oxidation in a vegetable tanning ext. soln., the colloid-chem. character of the soln. is also changed. A large part of the peptized phlobaphenes is pptd.

along with the dark colored humins, which are absorbed by the phlobaphenes, causing darkening. The very readily sol. peptizer is converted into a colloidal substance very similar to the phlobaphenes. An intermediate product of this oxidation is always benzoquinone, the quinhydrone of which colors the soln. an intense red, to which may be attributed the color of the phlobaphenes. The quinones are formed as intermediate products by the oxidation of the peptizer of the vegetable tannin colloids. Catechol contains a coumarin nucleus. By methylation a *p*-quinone, catechonetrिमethylene, is obtained. This seems to indicate the possibility of quinone formation by the oxidation of the catechol in plants. The easily decompd. peptizer, which consists of compds. easily split off from the polyphenols, is converted into humins while quinones containing several nuclei are more difficult to decompose. In tanning with gambier and catechu, the effect is not due to catechol but to dark polymers of catechol—quinhydrones. Compds. of a quinone character possess the property of forming colloidal peptized solns. to a high degree. Quinone is very easily oxidized by aq. permanganate solns. forming humins of high mol. wt. exactly as all vegetable tannins do. Colloidal complexes are obtained of unknown compn. and of undoubted tanning properties. Most theories of the quinone tannage claim that only those quinones with active oxygen are capable of tanning and dyeing. According to M.'s theory only those quinones which can form colloidal peptized solns. in aq. form are capable of tanning. Anthraquinone has no action on hide either in aq. or other solvents. Products containing anthraquinhydrone give weak tanning effects of quite a different nature from that of ordinary quinone. Phenanthraquinhydrone has only a weak tanning action on pelt, and the product can hardly be called leather. These expts. show that the far-reaching polymerization and oxidation processes usually associated with quinone and its homologs only take place with great difficulty with anthraquinone and phenanthraquinone, and colloidal peptized solns. are only produced under very special conditions. The quinone character of phlobaphenes is related to this question as they easily split off multinuclear quinones and are difficult to oxidize to colloidal humins. Tetrachloroquinone and turoquinone are very dissimilar to quinone in tanning action; they have not the tendency to form colloid complexes. Chloranil has no tanning action on pelt, but a trace of alkali added to a suspension in water produces some chloranilic acid which has a strong peptizing action on the rest of the chloranil. This forms a quinhydrone which gives humins on further oxidation. Such a chloranil suspension treated with alkali has a much greater action on pelt than all the quinones previously investigated. If pelt is treated with dil. aq. soln. of  $\alpha$ -diketone and then with very dil. caustic soln., aldolization ensues and further condensation to *p*-xyloquinone. There is no special tannage unless the pelt is left longer in the liquor so the pptd. quinones may be converted into colloidal peptized solns. Aldol gives a small portion of amorphous isomer which gives a leather exactly similar to formaldehyde leather. The author thus traces a direct connection between the aldehyde and quinone tannages. If ordinary quinone were stable in aq. solns. and formed no colloidal solns. it would have as little tanning action as anthraquinone. When benzoquinone has been converted into humins, only the peptizable substances are present, and no peptizer, with the result that it has no tanning action. But these humins have a very strong tanning effect if they are peptized by fresh additions of benzoquinone or hydroquinone, thus confirming the first assertion of the author's theory that only peptized substances can tan, but not the peptizer nor the peptized substances alone. If the peptization equil. is disturbed and the peptizer completely destroyed by oxidation, the tanning effect ceases to exist. The peptizers of the vegetable tannins consist of polyphenols which are easily oxidized to humins, while the peptized substances are stable multinuclear quinones of high mol. wt. which are not easily oxidized. If the air oxidizes the polyphenols into quinone-like humins, the equil. is disturbed the phlobaphenes are pptd. and there is a darkening

in color, owing to the adsorption of the humins formed from the peptizer. Benzoquinone does not give a true quinone tannage, but a humin tannage while quinonic phlobaphenes represent the true quinone tannage. The peptizer in vegetable-tanned leather is capable of oxidation to quinones and hence humins are formed. This change going on in the leather is the cause of the deterioration in vegetable tanned leathers.

J. S. ROGERS.

**Tanning materials in Germany.** ANON. *Halle aux cuirs* Sept. 8, 1918; *J. Am. Leather Chem. Assoc.* 13, 606-7.—The experience of tanners in Germany with Neradol indicates that while it tans rapidly certain precautions are necessary. Some skins are not suited for its use and the leather made with it disintegrates sooner or later. While this product helped materially to relieve the shortage of tanning materials in the Central Empires its use was forbidden by the Minister of War in Austria; in Germany the same would have happened, as a result of the complaints of its bad effects, if it had not been for the intervention of the Badische Aniline Works. This company controls Neradol and in 1916 sold 14,000,000 kg. at 55 marks per kg. As a compromise with the company, tanners can use now not over 30% of the quantity formerly used. After this ruling the Badische Works raised the price of Neradol from 55 to 90 marks per kg. and also tried to sell it as a tanning ext. under the name of "Tanol." Neradol has the fault of retaining  $H_2SO_4$  in the leather which causes irritation of the skin. A new product styled "Neradol-X" apparently overcomes this objection.

R. W. FREY.

**New methods of tannin estimation and their practical value as compared with the hide-powder process.** R. LAUFFMANN. *Collegium* 1918, 185-90; *J. Soc. Leather Trades Chem.* 2, 307(1918).—Zwick's process (*C. A.* 3, 2257) is useless when applied to mixed liquors, and the equiv. refractive indices before and after detannizing are influenced by the mode and temp. of leaching. Vanicek's assumption (*Collegium* 1909, 146) of a definite const. ratio between tannic acid and neutral matter in a tanning material is inadmissible, since the ratio alters on standing. Eglen's process (*C. A.* 8, 3251) is open to the same objection of varying proportion between the total solids and tannin. Gawaloski's modified process (*C. A.* 9, 3378) exts. resins and pectins with  $EtOH$  and  $Et_2O$  but with doubtful results, since insol. tans are counted as non-tans, and decompn. occurs when  $Cu$ -tannate is washed. Levi and Orthmann (*C. A.* 6, 814; 7, 1305, 1820, 3249) use inconst. factors. Kohn-Abrest (*J. Am. Leather Chem. Assoc.* 9, 260(1914)) and Singh and Ghose (*C. A.* 10, 1284) use very arbitrary methods. Errors in the hide-powder method are often due to fermentation of liquors or to improper treatment of the samples.

W. B. J.

**The detection of mangrove in mixture of tanning extracts—precision and caution.** E. SCHELL. *J. Soc. Leather Trades' Chem.* 2, 284-6(1918).—The detection of mangrove is still uncertain and erroneous conclusions are often made. The ethyl acetate figure is uncertain in mixts. and the amount of  $Cl$  and  $CaO$  is not positive proof of mangrove, since they could be introduced by use of waters containing  $Ca$  or  $Mg$  chlorides in making the exts. Color tests with mordanted strips of cotton are equally vague, and besides require much experience and many precautions. Colored ppts. from certain tests, such as Schell's cobalt reaction, do not permit the drawing of definite conclusions in commercial mixts. The following colored ppts. obtained by the author do not agree exactly with those given by Lauffmann in Stiasny's report on the differentiation of vegetable tanning materials (*C. A.* 6, 3540); ordinary quebracho, gray to dull gray; sulfited quebracho, light gray; mangrove, violet to dull violet; mimosa bark, light bluish gray; chestnut, olive-green; sumac, khaki; pine, dark sea green; divi divi, ashy green; valonia, deep green; cube, catechu reseda. S. tells how erroneous conclusions may be drawn from the cobalt reaction and certain exts. of solid quebracho poorly made

which react alkaline and contain appreciable quantities of alkali carbonates in the ash. As a control an alkaline ext. was made with a mixt. of  $\text{Na}_2\text{CO}_3$ ,  $\text{Na}_2\text{SO}_3$  and solid quebracho ext. free from mangrove. This gave with the cobalt test the dull violet characteristic of mangrove. These abnormal alk. exts. even when acidified do not give the normal quebracho reaction. With normal exts. and in conjunction with the other characteristic reaction the cobalt test is positive but becomes unreliable with abnormal exts.

R. W. FREY.

The effect of impure kaolin on the determination of acid in tan liquors. DOUGLAS McCANDLISH AND FRED B. LEDERER. *J. Am. Leather Chem. Assoc.* 13, 570-3(1918).—Abnormally low acidity results of vegetable tan liquors, detd. by the A. L. C. A. method for total acidity, were upon investigation found to be due to the kaolin used, and principally to traces of  $\text{MgCO}_3$  and appreciable quantities of iron present as impurities in the kaolin. The kaolin was labeled "acid washed" but indicated an alkaline condition by its behavior on settling. A  $\text{H}_2\text{O}$  ext. of the kaolin was not alk. to phenolphthalein and was neutral to methyl orange and hematin. Water-sol. matter detd. from 20 g. in 200 cc.  $\text{H}_2\text{O}$ , was 2 g. per g. of kaolin. Data on AcOH solns. ranging from 0.12 to 1.2% acid show that large errors may be caused by using such a kaolin in acidity detns. The loss of acid ranged from 33 to 92% for 20 mins. standing and from 40 to 99% for 1 hr. With the lower concns. of acid the end-point with hematin was good but became more indefinite with increasing concns. A similar set of expts. with an old kaolin showed no loss of acid and good end-points. With the poor kaolin the unsatisfactory end-point was due to the iron, which if present in sufficient quantity will give with hematin in AcOH soln. a violet-blue color which could be easily mistaken for the neutral point. It would seem that a kaolin desirable for acidity detns. should pass the following tests: "Shake 15 g. of kaolin vigorously with 250 cc. of 0.02 N acetic acid and allow to stand 1 hr.; withdraw 50 cc. of the settled soln. and titrate with 0.1 N NaOH, using hematin as indicator. A titration of 10 cc. and the characteristic end-point indicates that the kaolin is free from alkaline matter and sufficiently free from iron to permit its use for the purpose in view."

R. W. FREY.

The chrome tanning industry. ANON. *Board of Trade J.; Chem. News* 117, 233-5(1918).—The trades in hides and skins from India was largely with the U. S. and the Central Empires instead of with the United Kingdom. This is due in great measure to the fact that in the U. S. and Germany tanners have perfected and successfully used chrome-tanning processes much more extensively than have the English tanners. The tanning industry in the United Kingdom and in India favors development of chrome tanning in these countries. Up to the present time these countries have given preference to vegetable-tanned leather. The development of the one- and two-bath chrome-tanning processes is briefly reviewed. Rapidity of tannage, waterproofness, and compact leather after fat liquoring, and greater tensile strength are given as advantages of chrome-tanned leather.

J. S. ROGERS.

Investigation of one-bath chrome liquors. J. R. BLOCKEY. *J. Am. Leather Chem. Assoc.* 13, 573-81(1918).—See C. A. 12, 2708.

R. W. FREY.

A study of one-bath chrome liquors. JOHN ARTHUR WILSON. *J. Am. Leather Chem. Assoc.* 13, 566-9(1918).—A criticism of Blockey's article (C. A. 12, 2708, or preceding abstr.) in which is criticized the work of Thomas and Baldwin (C. A. 12, 2461). Chrome liquors are very complicated systems and not as simple as Blockey's explanations would indicate. His method for detg. "basicities" by means of the hydrogen electrode appears to have no foundation except for systems so const. as to need no such control. It assumes that the p. d. are functions only of the "basicity" and concn. of  $\text{Cr}_2\text{O}_3$ . Wilson and Kern (C. A. 11, 2740) show that it is possible to have 2 Cr liquors identical in "basicity" and  $\text{Cr}_2\text{O}_3$  content in one of which the Cr may be on the point

of pptn. while the other may require considerable alkali for pptn. because of the presence of neutral salts such as NaCl or Na<sub>2</sub>SO<sub>4</sub>. Further data on the "neutral salt effect" given in the second paper by Thomas and Baldwin (C. A. 12, 2460) show that it is possible to keep the "basicity" and the concn. of Cr<sub>2</sub>O<sub>3</sub> const. and vary the p. d. through wide limits. In such studies of Cr liquors more work should first be done on the effect of neutral salts on pure acid solns. Blockey's claim that the basicity value of 0.770 given by T. and B. for Cr<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub> should be 0.633 seems to be without grounds.

R. W. FREY.

**Note on the statement of basicity of chrome liquors.** H. R. PROCTER. Intern. Research Lab. *J. Soc. Leather Trades' Chem.* 2, 259(1918).—Procter does not consider the American way of stating basicity, e. g., Cr<sub>2</sub>O<sub>3</sub>/SO<sub>4</sub> or the European method as parts SO<sub>4</sub> to 52 parts Cr, as quite scientific or sufficiently general, since chrome liquors often contain chlorides and salts of other acids besides sulfuric. He suggests that basicity be stated "as the proportion of basic valences to acid ones, the normal salt being unity, thus Cr<sub>2</sub><sup>VI</sup>(SO<sub>4</sub>)<sub>3</sub><sup>VI</sup> would be 6/6 = 1; and Cr<sup>III</sup>Cl<sub>3</sub><sup>III</sup> would be 3/3 = 1; CrCl<sub>3</sub>OH and Cr<sub>2</sub>(SO<sub>4</sub>)<sub>2</sub>(OH)<sub>2</sub> would be 3/2 = 1.5; bisulfates and dichromates would be 0.5, etc." For the present this method of stating might be denoted by affixing basic to the figures. For chrome salts the rule would be that the wt. of Cr<sub>2</sub>O<sub>3</sub> found (in mg.) should be divided by ((152/6) × cc. N alkali used in neutralizing the acid).

J. S. ROGERS.

**Sodium sulfide in lime liquors.** H. HAYES. *J. Soc. Leather Trades Chem.* 2, 258(1918).—H. gives results comparing the method for the detn. of sulfide in lime liquors described below, with the ammoniacal zinc method described in Procter's *Leather Chemists' Pocket Book*. The authors method is as follows: Add excess of standard ZnSO<sub>4</sub> soln. to a known quantity of filtered lime liquor in a graduated flask, acidify with CH<sub>3</sub>COOH, make to vol., mix, filter, take aliquot of filtrate, add 2-3 cc. concd. HCl and 2-3 g. of NH<sub>4</sub>Cl, warm to 40° and titrate with K<sub>2</sub>Fe(CN)<sub>6</sub> soln., using uranium acetate as external indicator (Clowes and Coleman's *Quant. Analysis*). If 1 or 2 min. are allowed between the addition of reagent the end-point is quite distinct. The results obtained on lime liquor by H.'s method were 1.68 g. Na<sub>2</sub>S per l. as compared with 1.65 by the other method, and 4.73 g. Na<sub>2</sub>S per l. as compared with 4.68 g. per l. on a simple sulfide soln. H. believes his method, called the "Excess Zinc Method," is desirable when limes containing only 0.1% Na<sub>2</sub>S crystals are to be analyzed and accurate results are wished.

J. S. ROGERS.

**The Tilston-Melbourne liming process.** ANON. *Leather Trades Rev.* 51, 738-9 (1918).—This process has been established as a practical success in the United Kingdom. A cross-section view of the preferred form of installation is given. The pits should preferably be constructed to hold about 50 hides each and should have concave bottoms to assist the upward movement of the liquors. The usual pit can, however, be used. Along the full length of the bottom of each pit is a paddle arrangement which keeps the lime liquors constantly in motion, thus giving all parts of every hide a uniform liming. The paddle also on the forward stroke strikes the bottom edges of the hide giving a "bellowsing effect" which overcomes any tendency of the flesh sides to stick together. The machinery is run 5 hrs. each day, the liming is done in 2 stages, the first being 2 days with the old lime and the second 3 days with new lime and sulfide. The used lime liquors are drawn off from the bottom. By this process only 3 1/4 lbs. of lime per hide are used as against nearly 10 lbs. per hide with the usual system. Excellent results are obtained, the hair yielding to the slightest pressure, the grain being firm, and the pelt very uniformly and satisfactorily plumped. Besides the very material reduction of labor and time in the lime yard, there is considerable saving of hide sub-

stance, no danger of lime stains, and none of the heavy work of cleaning the lime bottoms from the stale pelts is necessary.

R. W. FREY.

The profitable recovery of proteins from tannery waste waters. C. LEE PECK. *J. Am. Leather Chem. Assoc.* 13, 417-28(1918).—P. describes tests made at Procter-Ellison tannery. The treatment consists of (I) screening, recovering hair, fleshings and undissolved hide material; (II) hydraulic classification, elimination of sand, silt and undissolved lime; (III) pptg. and recovering the dissolved protein substances, and settling out the finely divided cellular material, using acid to neutralize; dissolving and removing lime salts from the ppt.; (IV) prepg. the ppt. for the market. The results obtained in one month's test were: (a) One sq. ft. of settling area recovered 81.6% of suspended solids from 132 gals. of raw sewage daily. The effluent containing 163 pts. per million of suspended solids. (b) One sq. ft. settling area recovered 90.4% of suspended solids from 86 gals. of raw sewage daily. The effluent containing 158 pts. per million of suspended solids. Analyses of effluent according to Am. Public Health Assoc. methods are given. For each side of sole the vol. of sludge recovered was 4.6 gal., area of sludge bed required for each daily side was 10.8 sq. ft., and vol. concn. on sludge was 6.1. The wt. of dry solids was 1.56 lbs. The ammonia value at \$3.50 per unit was \$0.01767. The estd. cost of plant for sewage treatment, sludge recovery and drying was \$7.50 per daily side. The estd. cost of operation, including amortization, interest and freight of sludge to market and 10% losses was \$0.01. Three million gals. of tannery waste waters were treated. 37,000 gals of sludge were recovered, which contained about 14,500 lbs. of dry solids. The dry solids contained 6.47% N as  $\text{NH}_3$ . The returns to the tanner would be about twice the cost to the tanner.

J. S. ROGERS.

Influence of iron and organic matter on the iodometric estimation of chromium (LAUFFMANN) 7. Tintometry (SCHELL) 2.

Artificial sole leather. E. W. ERICSSON. Swed. 44,026, May 8, 1918. Addition to 43,588 (C. A. 12, 1604). In the manuf. of sole leather substitute by known processes, substituting seal fat, train oil, or linseed oil for the grease commonly used.

Tanning. A. TURNBULL and T. B. CARMICHAEL. U. S. 1,288,458, Dec. 17. Strong tanning solns. either of vegetable or mineral tanning compds. are mixed with about 10% of starch which has been gelatinized by heating to about 80°, in order to prevent to rapid tanning and hardening of the exterior portion of the hide and to secure a more uniform action of the liquor upon the entire thickness of the hide.

### 30. RUBBER AND ALLIED SUBSTANCES.

JOHN B. TUTTLE.

A review of the synthesis of rubber. ANON. *Caoutchouc et gutta-percha* 15, 9598-9601, 9624-6(1918).—A review.

JOHN B. TUTTLE.

A comparison of the effects produced by organic accelerators in the vulcanization of rubber. A. DUBOSC. *Caoutchouc et gutta-percha* 15, 9635-7(1918).—D. gives the results of some expts. comparing the action of inorg. accelerators with org. The compd. used contained 90 parts pale crepe, 10 parts S, and small quantities of accelerators and was vulcanized in steam 1 hr. at 15 kg. pressure. A table of the coeffs. of vulcanization shows that the org. accelerators produce a higher coeff. and a greater resistance to elongation.

JOHN B. TUTTLE.

**Vulcanization accelerator.** A. HUTIN. *Caoutchouc et gutta-percha* 15, 9596-8 (1918).—See C. A. 12, 103. JOHN B. TUTTLE.

**Vulcanization researches.** B. J. EATON. *Agr. Bull. Federated Malay States* 6, 422-3 (1918); cf. C. A. 12, 1011.—A summary of the work of the Agricultural Department at Kuala Lumpur for the first half of 1918. Attention is called to the injurious effect caused by the use of alum in coagulation. The effect of certain substances on the rate of vulcanization was studied. Starch was without effect, but boric, tannic, molybdic and phosphotungstic acids all had a retarding effect when used to the extent of 1 to 2%. The larger amts. have a greater effect than the smaller, and the effect varies with different kinds of rubber. JOHN B. TUTTLE.

**Reclaiming of vulcanized rubber.** A. DUBOSC. *Caoutchouc et gutta-percha* 15, 9646-8 (1918).—D. considers that in vulcanization, the S is first absorbed by the gum, after which a chem. reaction takes place. According to this idea one would find in vulcanized rubber (1) chemically combined rubber and S, giving a hydrochloride insol. in  $\text{CHCl}_3$ ; (2) stable rubber, containing S which can be extd. by acetone; it forms a hydrochloride insol. in  $\text{CHCl}_3$ ; (3) metastable rubber, in which there is only a physical mixt. of rubber and S; it forms a hydrochloride sol. in  $\text{CHCl}_3$ . Since the value of reclaimed rubber depends largely on the amt. of metastable rubber, D. has developed a method to det. the % of this material. Grind the rubber to pass 120-mesh sieve and treat with anhydrous HCl for 24 hrs. The temp. in the reaction flask must not exceed  $35^\circ$ . Wash with hot, then cold water, hot 90% EtOH, then cold EtOH, dry at  $60^\circ$  and cool in a desiccator. The product is a white powder, insol. in EtOH,  $\text{Et}_2\text{O}$ ,  $\text{Me}_2\text{CO}$ ,  $\text{C}_6\text{H}_6$ , and  $\text{CS}_2$ . It contains the hydrochlorides of polyprene sulfide, stable and metastable rubber. A weighed portion is extd. with  $\text{CHCl}_3$ , the residue dried at  $60^\circ$  and weighed, the loss being metastable rubber. The dried ext. can be weighed, or treated with pyridine on a steam bath for 6 hrs. using a reflux condenser, filtered on a tared filter paper, washed with hot, then cold acetone, then 95% EtOH. It is dried at  $60^\circ$  and weighed. The rubber thus obtained is elastic, and sol. in all the usual rubber solvents. JOHN B. TUTTLE.

**Statistics on rubber plantations in the Middle East.** HENRI JUMELLE. *Caoutchouc et gutta-percha* 15, 9533-42 (1918).—A review of the growth of the rubber plantation industry in Ceylon, Malay, Burma, Netherland Indies and nearby territories. JOHN B. TUTTLE.

**The influence of dilution water on the latex, with reference to premature coagulation while diluting to standard strength.** J. C. HARTJENS. *Archief v. d. Rubber-cultuur in Nederl.-Indië* 2, 163-86; *Chem. Weekblad* 15, 1390-1 (1918).—Premature coagulation while dilg. to 15% strength is largely due to Ca salts in the water. If the only available water supply contains much Ca, it is even better to omit entirely the diln. to standard strength. Expts. with anti-coagulants showed that NaOH, PhOH and Na oxalate are the most effective ones. JULIAN F. SMITH.

**Flowers of sulfur and sublimed sulfur.** NOYER. *Caoutchouc et gutta-percha* 15, 9661-3 (1918).—The varying descriptions given to flowers of S by different authors suggest to N. that a real difference exists between sublimed S and flowers of S. He believes that the insoly. of flowers of S in  $\text{CS}_2$  suffices to distinguish the two kinds. For rubber manuf. flowers of S should possess 33% insol. in  $\text{CS}_2$ , and the % insol. in  $\text{CS}_2$  should tell the amt. of flowers of S in sublimed S. JOHN B. TUTTLE.

**Regenerating rubber.** E. ZAPPERT. *Holl.* 2,486, Oct. 1, 1918. Old rubber material contg. vegetable fibers is treated in a closed vessel by heating with a mixt. of  $\text{H}_2\text{SO}_4$  and a resin oil from which the turpentine has been previously removed by distg.

# CHEMICAL ABSTRACTS

Vol. 13.

MARCH 20, 1919.

No. 6

## I. APPARATUS.

L. C. JONES.

**Platinum economy in the industrial chemical laboratory.** E. C. MUESER. *Chem. Met. Eng.* 20, 69(1919).—A general review on the use and care of Pt ware. No new matter. F. W. SMITHER.

**Hydraulic separation as applied to the recovery of fine coals, shales, and clays.** JOHN M. DRAPER. *Trans. Eng. Ceram. Soc.* 17, 213-25(1918).—A new hydraulic app. is described which has been used successfully in recovering fine-grained coal (down to 100 mesh) from the accompanying shale. It consists of a vertical tower in which the descending charge meets a rising flow of water, the rate of flow being regulated to accomplish the floating of the particles of lower sp. gr. while the heavier particles sink. Materials with sp. gr. differences as low as 0.06 can be sepd. The app. seems applicable to clay purification. C. H. KERR.

**Electrical apparatus for boiling water.** F. BURMANN. *Electrician* 81, 740; *Elektro-techn.* Z. No. 13(1918).—Two or more C plates or cylinders sepd. by insulating rollers are immersed in the water to be heated. Tests have shown that it requires 1 hr. to heat 300 l. of water to about 30°. Twenty amps. at 220 v. were required. This gradually rises to 34 amps. By cutting out plates, any temp. desired may be maintained. Tests were also made with cylindrical electrodes on smaller quantities. W. E. R.

**Sumner elastic-limit recorder.** J. L. JONES AND C. H. MARSHALL. *Proc. Am. Soc. Testing Materials* 18, Pt. II, 478-83(1918).—A device consisting of a semi-automatic solenoid is described. It is accurate, rapid, and enables one man to do the work that has usually required 3 men. It has been used in connection with the Ewing extensometer over a considerable period of time and the data obtained have been uniformly satisfactory. One especially valuable feature is the fact that the card on which the test is made can be filed as a permanent record. S. G. SIMPSON.

**Optical pyrometer.** ANON. *Elec. Rev.* 74, 159(1919).—This portable app. has a telescope which brings the image of the heat source in the plane of a carefully aged W lamp filament. A storage battery current through the lamp is adjusted until the filament blends with the image of the heat source. The temp. of the filament (or heat source) is shown on the scale of a milliammeter in series with the lamp. The milliammeter reads degrees directly, or the temp. corresponding to the current may be read from a calibrated curve supplied with the instrument. The telescope weighs but a few ounces. A case, containing the battery, rheostat and milliammeter weight about 10 lbs. and can be slung over a shoulder. The temp. range is from 600° upward. C. H. ELDRIDGE.

**Photometric apparatus for measuring the illuminating value of fluctuating sources of high candle power.** A. P. TROTTER. *Gas J.* 144, 658(1918).—The app. was originally devised for the English Ministry of Munitions for comparing the illuminating values of flash lights, flares, star-shells, etc. Conditions demanded a photometer which should be portable, self-contained, direct-reading, requiring no adjustment during use, suitable for either outdoor or indoor work, and requiring no special training or

photometric knowledge for operation. Two such photometers were produced; one by J. G. Clark, the other by J. S. Dow. The Clark instrument is a tube 25 in. long by 3 in. diam., the interior whitened and illuminated by an elec. glow lamp placed at one end. A slot 0.2 in. wide extending nearly the whole length of the tube is covered with a strip of thin metal having perforations preferably in form of letters. This strip is painted white and receives the illumination to be measured. In reading the illumination a point is estd. where the brightness of the interior of the tube is equal to that of the exterior strip of metal, these readings being later compared with a previously prepared calibrated scale registering the illumination of each perforation. The lamp is supplied by a portable battery and so long as the voltage is constant the calibration may be depended upon. The disadvantage is that the illumination falls off rapidly from the bright end to the darker end. The Dow instrument is a box 11 × 11 × 4 in. The observer looks through an opening in one side of the box and sees on the farther side a grid of 14 slots in a white card. The grid is illuminated by an elec. lamp placed on one side of the box and screened from the observer. Readings are made by looking through the slots at a detached test screen which receives the illumination to be measured. As in the other photometer, a point is taken where the brightness of the slotted card appears to be equal to that of the test screen. A graduated screen gives a measure of the illumination thus detd. A range much wider than that afforded directly by the slots is obtained by using test screens of various tints of gray placed about 1 m. distant. If the observer finds that the balancing point is near the darker end, he can at once direct his view to an adjacent screen of a gray tint. The balancing point becomes shifted to the other end of the scale. Each tint has a definite multiplying factor found by expt.

J. L. WILEY.

VIGREUX, HENRI: *Le soufflage du verre dans les laboratoires scientifiques et industriels*. Preface by M. Haller. Paris: H. Dunod et E. Pinat. 248 pp. 14 francs 40. For review see *L'industrie chimique* 6, 32(1919).

**Drying apparatus.** O. H. ABBOTT. Brit. 120,635, Nov. 21, 1917. A drying chamber provided with trays in tiers is fitted with a series of baffles projecting approx. horizontally from the wall, each baffle being in line with the bottom of a tray. The baffles are of graduated lengths, the bottom one being the shortest so that the inlets to the trays are successively reduced in width.

**Extraction apparatus.** J. I. THORNYCROFT. Brit. 120,448, Nov. 12, 1917. A diffuser app. for extg. sol. substances from vegetables, or sugar sirup from sugar beet, consists of a vertical column up which the vegetable substance is forced by a piston working in a vertical cylinder at the base of the column, while the extg. liquid passes down the column. Constructional details and operation are specified.

**Oil-filter.** G. W. WILMOT. U. S. 1,287,160, Dec. 10.

## 2. GENERAL AND PHYSICAL CHEMISTRY.

WILLIAM D. HARKINS AND E. B. MILLARD.

The work of Charles Gerhardt. M. TIFFENEAU. *Rev. scientifique* 55, 586, 750 (1917); 56, 168(1918). E. H.

Physical chemistry and its bearing on the chemical and allied industries. JAMES C. PHILIP. *J. Roy. Soc. Arts* 67, 94-102, 108-18, 122-31(1919). E. H.

Chemistry, chemists and the war. P. CARRÉ. *Rev. sci.* 56, 233-6(1918).

Science and the after-war period. GEORGE K. BURGESS. *J. Wash. Acad. Sci.* 9, 57-70(1919); *Sci. Monthly* 8, 97-108(1919). E. H.

Chemistry at the Indian Institute of Science, Bangalore. *J. Soc. Chem. Ind.* 38, 4-5R(1919). E. H.

Inter-Allied conference on international organizations in science. C. G. K. *Nature* 102, 325-7(1918).—Minutes of the conference of the Committee of Inquiry held in Paris, Nov. 26-29 (1918). This committee was constituted at a meeting of representatives of academies of the Allied countries and of the United States in London, Oct., 1918, for the purpose of prepg. a general scheme of international organizations to meet the requirements of the various branches of scientific and industrial research, including those relating to national defense. Definite progress was made in the institution of three associations: (1) astronomy, (2) geophysics; and (3) union of chem. societies. W. H. ROSS.

An institute of physical and chemical research for Japan. ANON. *Nature* 102, 294-5(1918).—A review of the purpose and scope of the Institute of Physical and Chemical Research in Japan which came into existence as a legal body in March, 1917. W. H. ROSS.

The Manchester exhibition of British science products. ANON. *Nature* 102, 354-6(1919).—The exhibit to which about 240 firms contributed consisted of such products as chemicals, dyes, intermediates used in organic synthesis for dye manufacture and for explosives, precision machinery, measuring instruments, physical app., etc. W. H. ROSS.

The purification by sublimation and the analysis of gallium chloride. THEODORE W. RICHARDS, W. M. CRAIG AND J. SAMASHIMA. *J. Am. Chem. Soc.* 41, 131-2(1919).—A new method for the purification of Ga salts was employed, involving first the burning of Ga in pure, dry Cl, then fractional distn. of the chloride in pure Cl, next in N, finally sublimation *in vacuo*. The app. was devoid of rubber connections or ground glass joints. Examn. of the product in a Hilger wave-length spectrometer showed no trace of impurity. In a preliminary detn. of the at. wt., the values 70.09 and 70.11 were obtained. The work is being continued. R. E. HALL.

The purification of gallium by electrolysis, and the compressibility and density of gallium. THEODORE W. RICHARDS AND SYLVESTER BOYER. *J. Am. Chem. Soc.* 41, 133-4(1919).—Sepn. of Ga from In by means of the different solubilities of the hydroxide in caustic alkali was tested without success. More promising results were obtained by the electrolytic method. Ga obtained in this manner from material previously purified by the hydroxide method melted at 30.8°. The compressibility of pure solid Ga is  $2.09 \times 10^{-8}$ ; contaminated with a few % of In,  $1.97 \times 10^{-8}$ ; of the liquid at 30°,  $3.97 \times 10^{-8}$ . The densities of solid and liquid Ga are, resp., 5.885 and 6.081. R. E. H.

Some physical constants of mustard "gas." LEASON H. ADAMS AND ERSKINE D. WILLIAMSON. *Geophys. Lab. J. Wash. Acad. Sci.* 9, 30-5(1919).—The values of  $\Delta v$  as a function of pressure are expressed by  $-\Delta v/v_0 = 0.118[1 - e^{-0.364 \cdot 10^{-3}(P - P_0)}]$  in which  $v_0$  is sp. vol. at 31.5° and  $P_0$  is 392 megabars. From this, the compressibility at 0, 1000, and 2000 megabars is, resp.,  $49.5 \times 10^{-8}$ ,  $34.4 \times 10^{-8}$ , and  $23.9 \times 10^{-8}$ . The f. p. ranges from 13.9° at 1 megabar to 38.9° at 1800 megabars. The vol. change on freezing at various temps. and pressures is also noted. From these data, the latent heat of melting is 25 cal. per g., and the f.-p. lowering const. is 6.5° (1 mol. solute per 1000 g. solvent). At 38°, no different forms of solid mustard gas were found up to 12000 megabars. R. E. HALL.

The cryoscopic constant of asymmetric heptachloropropane,  $\text{CCl}_2\text{CCl}_2\text{CCl}_2\text{H}$ . J. BÖRSSEN AND J. BENEDICTUS. *Rec. trav. chim.* 37, 121-9(1918).—Heptachloro-

propane (*a*) seemed suited as a cryoscopic solvent because it m. about 29°, it is easily purified by distn. and it is not hygroscopic. The cryoscopic const. was found to be about 120. The soly. of HO derivs. and acids in (*a*) is not very great. For acids (*a*) is a pronounced associating solvent: so pronounced that acids like undecylenic, lauric, palmitic and stearic form double mols. The alcs. show the same anomaly. At very great diln. the mol. wt. is nearly normal but rises quickly with the concn. The hydrocarbons, the chlorides, the amines and the esters behave normally. (*a*) is recommended as a cryoscopic solvent for all these compds. except alcs.: with the acids the mol. value may be obtained by dividing by two. The (*a*) used was purified by distn. until the f. p. was const. within 0.05°. The Beckmann app. with a motor-driven Ni agitator was used. 75 compds. were investigated and the numerical data are given in tables and graphs. The graphs show that the alcohols show an increase in the association with the temp. as well as with increasing mol. wt. The tertiary alcohols are little or not at all associated.

E. J. WITZEMANN.

**Critical phenomena.** WILLIAM R. FIELDING. *Chem. News* 117, 379-83(1918).—In a paper not yet published F. has proved that for inorg. elements and compds. the relation  $C. T. = (1.714 \times B. P.) + 3.3^\circ$  (all temps. being on the abs. scale). If crit. temps. are plotted against crit. pressures, not all substances lie on one curve; there appears to be a separate curve for each group of elements or similarly constituted compds. The formula  $(C. T. + 236.2)/\sqrt{C. P.} = 70.9$  applies to the elements and a similar formula  $(C. T. - X)/\sqrt{C. P.} = k$ , where *X* and *k* depend on the series to which the substance belongs, applies to inorg. compds. E. Ariès has calcd. the crit. data of Hg vapor from the behavior of Kr, A, and Xe, the first two of which, like O and He, behave in an irregular manner and do not lie on the crit. curve. The formula  $C. T. \times \sqrt{C. P.} = \text{const.}$  applies to org. compds. The C. T. and C. P. of compds. are not the sums of the C. T. and C. P. of their constituents; but in inorg. compds. as the C. T. rises the C. P. rises and the value of R falls (in any particular series of compds.)  $R = C. P.$  of the substance calcd. from its constituents divided by the C. P. of the substance. In inorg. compds. as the C. T. rises the C. P. falls and the value of R rises (in any particular series of similar compds.). In the case of the benzene derivs. the value of  $C. T. \times \sqrt{C. P.}$  is highest for the ortho-position and lowest for the para-position. The value of  $C. T. \times \sqrt{C. P.}$  is slightly higher for the normal than for the iso-position. As the number of benzene rings in a compd. increases so does the value of  $C. T. \times \sqrt{C. P.}$ . The substitution of one phenyl radical for H in a methane mol. raises the value of  $C. T. \times \sqrt{C. P.}$ ; the introduction of a second phenyl radical raises it still further. The introduction of one methyl radical into the benzene ring reduces the value of  $C. T. \times \sqrt{C. P.}$ ; a second methyl radical (in the ortho-position) causes no further change; a third methyl radical probably causes no further change (if the methyl radicals are in the 1,2,3-positions). In the case of the benzene ring with a side chain the value of  $C. T. \times \sqrt{C. P.}$  will probably tend to become const. when the possibility of isomerism has become established. Numerous tables of crit. data are given exemplifying the above conclusions.

F. P. PHELPS.

**The characteristic equation of fluids.** PIERRE WEISS. *Compt. rend.* 167, 364-6 (1918); cf. *C. A.* 12, 2469.—Van der Waals' equation assumes that the "internal pressure" is proportional to  $1/v^2$ . W. has used a more general expression,  $\pi = a/q^\eta$ , where *v* is the vol.  $\eta$  is found by plotting the log of the internal pressure against  $\log 1/v^2$ . Curves are shown for isopentane, argon and ethylene. The curves are straight lines, with sudden changes in slope corresponding to different values of  $\eta$ . For ethylene a sep. value of  $\eta$  is given for use at high temps. The complete equation of state is now  $(p + a^\eta/v)(v - b) = \zeta RT$ . For isopentane,  $\eta = 1.65$  and 2.5;  $\zeta = 1.38$  and 1.20. For

A,  $\eta = 2.09$  and  $1.56$ ;  $\zeta = 1$  and  $1.56$ . For ethylene  $\eta = 2$  and  $1.5$ ;  $\zeta = 1.07$  and  $1.43$ ; while at high temps.  $\eta = 1.73$  and  $\zeta = 1.20$ . F. C. HORR.

Studies on the coagulation of colloidal solutions by complex metallic salts. I. Coagulation of arsenious sulfide by complex cobalt salts. K. MATSUNO. *Tokyo Kwagaku Kawai Shi (J. Tokyo Chem. Soc.)* 39, 908-32(1918).—A certain vol. of the complex Co salt soln. of various concns. was added to 1 cc. of colloidal  $As_2S_3$  soln. (0.0376 mol.) and the threshold value, or the concn. of the electrolytes at which the coagulation of the colloidal soln. begins, was detd. The following results show the relation between the valency of complex positive ions and their threshold values:

|                      |           |          |           |           |   |            |
|----------------------|-----------|----------|-----------|-----------|---|------------|
| Valency.....         | 1         | 2        | 3         | 4         | 5 | 6          |
| Threshold value..... | $1/187.4$ | $1/3000$ | $1/18000$ | $1/53230$ | — | $1/240000$ |

In the case of common salts, however, varying results were obtained. It might be ascribed to the fact that equiv. solns. do not actually yield ions of the same valency owing to the formation of some complex salt. From the exptl. data was deduced the equation  $S_n = S_1 \times 1/n^4$ , in which  $S_n$  is the threshold value of  $n$ -valent complex salt. By the study of the threshold value, the author explained the chem. change of aquo Co or other complex salts in their aq. soln. S. KOMATSU.

The rhythmetic precipitation of silver chromate. TOKIHARU OKAYA. *Phys. Inst., Imperial Univ., Tokyo. Proc. Tokyo Math. Phys. Soc.* [2] 9, 442-62(1918).—A revision and extension of the theoretical treatment of the second Liesegang phenomenon by G. Pierce and H. Morse using the latter author's exptl. data. P. and M.'s theory was based simply on Ostwald's pptn. theory. Owing to the effect of the diffusion of a Ag salt in gelatin containing chromate, there may occur at some place a strength of the soln. which is supersatd. with respect to the salt and yet the pptn. does not take place until the concn. oversteps some definite value which may be called the metastable limit. In O.'s opinion it is not sufficient to cause pptn. for the concns. of the reacting ions to attain the metastable limit, but it is necessary that the amts. of their accumulation shall exceed a certain limit. As soon as the amts. of accumulation attain this limit the pptn. will begin. This limit is called the "separation limit." The mathematical theory of rhythmetic pptn. is worked out in detail, using the "separation limit" as an assumption. F. P. PHELPS.

The multarotation of gelatin and its significance in gelation. C. R. SMITH. *J. Am. Chem. Soc.* 41, 135-50(1919).—From studies of the effect of temp. on the multarotation of gelatin solns. the author concludes that "there probably exist 2 forms of gelatin, one, which has been designated sol form A, stable above  $33^\circ$  to  $35^\circ$ , and the other, the gel form B, stable below  $15^\circ$ ." He develops a formula for what he believes to be a bimol. reaction, with an equil. thermally reversible between these limits. Increase in levorotation parallels increase in viscosity, and is held to indicate increasing formation of gel form B. Gelatin sols dried above  $35^\circ$  and gels dried below  $15^\circ$  give different solid forms. JEROME ALEXANDER.

The state of substances in solution in absolute sulfuric acid. VIII. Reply to A. Hantzsch. G. ODDO with A. CASALINO. *Pavia. Gazz. chim. ital.* 48, I, 17-44(1918); cf. C. A. 2, 930, 1773, 1775; 3, 604, 1607; 4, 533; 5, 879, 1744, 3798; 12, 1180.—This constitutes a complete and detailed reply to criticisms of Hantzsch of long standing. In the latter part serious accusations are made against the editor of *Z. physik. Chem.* The paper is divided into 6 sections. In the first 2 sections H.'s cryoscope and some typical runs with it are described. O. built an app. exactly like that used by H. and found it unsatisfactory for a number of reasons. Moreover the consts. obtained for picric acid, phthalic anhydride,  $Me_2SO_4$  and  $C_6H_5(NO_2)$ , in abs.  $H_2SO_4$  when detd. with use of H.'s app. and method are quite irregular. O. offers to lend the app. to

anyone wishing to repeat the detns. In the section on solvent O. replies in detail to all of H.'s misunderstandings and errors largely by repeating and emphasizing material previously published. In the section on the const. O. states that H. has attempted to correct his data on the cryoscopic const. using the same compds. used in part by O. The expts. were repeated by O. in his own cryoscope and show again that in abs.  $\text{H}_2\text{SO}_4$ ,  $\text{C}_4\text{H}_2(\text{NO}_2)_2$ , anhydrous oxalic acid, phthalic anhydride and  $\text{Me}_2\text{SO}_4$  show evidences of decompn. as indicated by the irregular values obtained for  $K$ . The mean value obtained for  $K$  was 68.9. In the section on ethers and esters, O. critically examines H.'s criticism of his own interpretation of the behavior of these compds. in abs.  $\text{H}_2\text{SO}_4$  and experimentally shows the latter to have been mistaken. The last section consists of replies to H.'s criticism on the calcn. of mol. percents and concns. O. in a final section airs his grievance with the *Z. physik. Chem.* and volunteers to substantiate his claims with documentary evidence.

E. J. WITZEMANN.

**Remark on the internal friction of quartz filaments at low temperatures.** C.-E. GUYE AND P. BARBIER. *Arch. sci. phys. nat.* 46, 326-8(1918); cf. *C. A.* 10, 2431.—Guye and Einhorn have shown previously that the internal friction of a quartz filament, as measured by the logarithmic decrement of the torsional oscillations of the filament, diminishes rapidly with falling temp. down to  $-79^\circ$ , after which there is little change. In the present paper an attempt is made to answer the question as to whether or not the extremely slowly diminishing damping of the oscillations below  $-79^\circ$  may have been a residual external damping which resulted either from the friction between the moving parts and the residual gas present in the app., or from some force transmitted to the support of the filament during its oscillations. Expts. now made show that the decrement at  $0^\circ$  in air (1 cm. pressure) is the same as in  $\text{CO}_2$ , whereas, if the damping were due to the gas the decrements should differ by 17%. Although the action of an external force on the suspension is not yet excluded, it seems probable that the slow diminution of the internal friction of quartz filaments below  $-79^\circ$  is a fact, and especially so since other properties of quartz filaments, such as the dilation and coeff. of elasticity, are abnormal at low temp.

R. H. LOMBARD.

**The thermal conductivity of air.** E. O. HERCUS AND T. H. LABY. *Proc. Roy. Soc. London (A)* 95, 190-210(1919).—Out of 8 detns. the two which were considered most reliable differed by 1.2%. Considerable discussion is given of the results of others, and of their bearing on the theory.

#### 4. ELECTROCHEMISTRY.

COLIN G. FINK.

Henry T. von Boettinger. K. ELBS. *Z. Elektrochem.* 24, 183; illus.—An appreciation. C. G. F.

Development of hydroelectric resources in eastern United States. D. H. COLCORD. *Elec. Rev.* 74, 207-9(1919).—A review. C. G. F.

The development of hydroelectric power in Canterbury (New Zealand). L. BIRKS. *Electrician* 82, 116-8(1919).—A detailed account of the new undertaking.

The electrochem. industries that have sprung up include an electrolytic detinning plant. Caustic soda, Cl, carbide and elec. steel plants are about to be started. C. G. F.

**Electric furnace installation.** T. R. HAY. *Iron Age* 101, 735(1918).—When the use of an elec. furnace is being contemplated, it is important to give careful attention to the consideration of (1) ample finances, (2) proper conception of the function of an elec. furnace, and (3) correct decision as to the proper size and type of furnace.

W. E. RUDER.

**Results with a Rennerfelt furnace.** O. FRICK. *Iron Age* 101, 563(1918).

C. G. F.

**Developments in the Rennerfelt furnace.** H. A. DE FRIES AND J. HERLENTUS. *Iron Age* 103, 190-1(1919).—A round shell with a removable dome-shaped roof is now employed which permits a better heat distribution and a more accessible hearth. A number of improvements have been made in the electrode mechanisms. Since it had been found that the highest efficiency was obtained with the furnace at a certain fixed and const. distance between the tips of the electrodes and the top of the charge, the electrodes of the newer furnaces have been made so that they can tilt in a vertical plane, thus allowing the electrodes to follow the charge as it melts down. The most important improvement is the tilting of the side electrodes to such an extent that arcing to the slag can take place. The time for desulfurizing and killing in the basic process has been considerably shortened and a superior steel obtained, through decreasing the depth of the bath. The larger furnaces are now furnished with a cradle and rack.

H. JERMAIN CREIGHTON.

**Triplex process of making electric steel.** T. W. ROBINSON. *Iron Age* 101, 1471-7 (1918); *Chem. Met. Eng.* 19, 15-20(1918).—A description of the large new plant of the Illinois Steel Co. at South Chicago where three 25-ton Héroult furnaces are now in operation. These produce about 12000 tons of steel per mo. This combined with the two old furnaces give the plant a capacity of about 17000 tons of elec. steel per mo. With 4 furnaces working on the triplex process load factors of 75 to 80% are not unusual. The furnaces are operated on a reducing slag only, and after the steel is thoroughly dead-melted, the current is reduced to obtain a proper pouring temp. All pouring is subject to careful pyrometric control. The steel is teemed in inverted molds with refractory hot tops. In transferring open-hearth metal to the elec. furnace, it is the aim to have the metal slightly lower in C and Mn. A table of test results shows that elec. steel is very much superior to open-hearth steel in ductility and resistance to shock at temps. of  $-18^{\circ}$  and lower. At temps. above this, the open-hearth steel is somewhat superior. MATHEWS and HOWE in discussion, as well as the author, discuss the probable future of the elec. steel industry in very optimistic terms.

W. E. RUDER.

**Temperature uniformity in a laboratory electric furnace.** J. B. FERGUSON. *Phys. Rev.* 12, 81-94(1918).—This can best be accomplished by means of 3 independent resistance wire heaters in addition to end plugs. The entire region should be surrounded by a layer of conducting material sufficient to smooth out any local heatings, and the whole furnace should be so insulated that the effect of non-uniformity in the temp. of the furnace surroundings is negligible. Alternate layers of good and poor conductors will reduce the total amt. of insulation necessary. This type of furnace (see fig.) may readily be converted into a simpler type. This furnace yielded

a temp. uniformity of  $\pm 1/2^\circ$  at temps. ranging from 620 to 1190° and at 1000° and 1190° a temp. constancy of  $\pm 1/4^\circ$  for periods exceeding 1 hr. Curves and tables of results are given.

W. E. RUDER.

**Aktie Selakabet Karbidindustri.** ANON. *Farmand* 1918, No. 51, 1139.—The Aktie Selskabet Karbidindustri has been founded recently in Fredrikstad, Norway, with a capital Kr. 1,000,000 and with the purpose of utilizing S. Uthheim's methods of making AcOH and EtOH from  $\text{CaC}_2$ . A plant has been erected for this purpose. From acetylene, acetaldehyde is produced which serves as raw material for manuf. of AcOH, alc., chloroform, artificial rubber, etc. The plant produces 100 kg. acetaldehyde daily but will shortly be extended to a capacity of 3500–4000 kg. daily.  $\text{CaC}_2$  is one of the principal products of Norway's elec. industry and it is produced there at a far lower price than in any other country.

G. HALLBERG.

**Cost of the Muscle Shoals nitrate plant.** BENEDICT CROWELL. *Elec. World* 73, 281(1919).—The estd. cost is \$14,000,000. About 72,000 h. p. continuously will be developed in even the very driest years. The machinery is capable of generating 120,000 h. p.

C. G. F.

**The fixation of atmospheric nitrogen in Germany during the war.** ANON. *J. four électrique* 28, 15–6(1919).—A brief review.

C. G. F.

**Electro-cyanidation of gold and silver ores.** RUSH T. SILL AND HARLEY A. SILL. *Mining and Oil Bull.* 4, 181(1918); *Eng. Mining J.* 106, 988–9(1918).—The old Pelatan and Clerici equipment consisted of a wooden tank with an amalgamated Cu plate on the bottom as cathode, and as anode a rotating cast-Fe shaft carrying 4 arms to keep the pulp in suspension. Mechanical and other difficulties with this app. have been overcome and the process has been made economical and efficient. Compared with standard methods elec. cyanidation has a wider field because it can treat Au and Ag ores in the presence of a larger amt. of base metals, the time of the process is  $1/8$  to  $1/30$  as great, the soln. is in contact with the ore a shorter time, the cyanide is regenerated by the elec. pptn. of the metals, and weaker soln. can be used. A c. d. of 2.75 amp. per sq. ft. (0.29 amp. per sq. dm.) is best. Lime and NaCl are added to the soln. The latter increases the cond. of the soln. and also yields Na, the action of which both aids the amalgamation and increases the protective alkalinity. In a  $2 1/2$ -hr. treatment the pulp travels about 7 mi. over the plate.

A. BUTTS.

**Electrometallurgical treatment of nickel minerals in New Caledonia.** ANON. *J. four élec.* 24, 3(1919).—Hitherto it has been impossible to obtain ferro-Ni in the elec. furnace low in C and Si. In 1912–1913, garnierite was treated in the elec. furnace during 8 months on a production scale. The charge was mineral, finely powdered wood charcoal, and lime to form a basic slag. Products were ferro-Ni with 50 and 75% Ni, C less than  $1/2\%$ , Si about 0.2%, and with losses of Ni less than 5%. The furnace was of 2-electrode type of 400 kw. capacity. Elec. energy consumed per ton of 50% ferro-Ni was 13000 kw. hr., with electrode consumption of 125 kg. per ton.

C. H. ELDRIDGE.

**Electromotive behavior of oxygen and its anodic production at voltages below the reversible oxygen potential. (Platinum oxides.)** G. GRUBE AND B. DULK. *Z. Elektrochem.* 24, 237–48(1918).—The authors assume that the overvoltage of Pt is due to the formation of Pt oxides which are very unstable and decompose readily into metal and free O. In line with this theory it is assumed that the reaction  $2\text{O} \longrightarrow \text{O}_2$  proceeds very slowly compared to the reactions  $\text{Pt} + x\text{O} = \text{PtO}_x = \text{Pt} + x/2\text{O}_2$ . The e. m. f. of the O electrode was calcd. by Nernst (*Z. Elektrochem.* 11, 835(1905)), Lewis (*J. Am. Chem. Soc.* 28, 158(1906)), and others to be 1.23 volts. The authors believe that their present exptl. results strengthen the assumption that 1.23 is the cor-

rect O potential. As a depolarizing agent, the authors use a superimposed a. c. (cf. Bennewitz, *C. A.* 4, 1708). The auxiliary electrode *c* (see fig.) consisted of a 0.9 cm.

R and  $R_1$  = Rheostats  
L = Choke Coil  
T = Transformer

diam. Pt disk suspended directly opposite the Pt anode (*a*), allowing but a few mm. between the faces of the 2 electrodes. The faces of the anode and of the cathode (*c*) were 13.95 sq. cm. each. The electrolyte was 2 *N*  $H_2SO_4$ , and later *N* NaOH. The normal electrodes used for reference were  $Hg | Hg_2SO_4 | H_2SO_4$  ( $\epsilon_h = 0.676$  volts, 18°) and  $Hg | HgCl | KCl$  ( $\epsilon_h = 0.286$  volts). All measurements were made at room temp., using the Poggendorf-Ostwald compensation method with the capillary electrometer. The a. c. density was varied between 0 and 0.4 amp. per sq. cm. while the d. c. density was maintained const. at 0.0072, 0.0145 or 0.0217 amp. per sq. cm. (the last = 20 amp. per sq. ft.). The superposition of a. c. lowers the d. c. potential very markedly. Not only does the a. c. act as a depolarizer, bringing the O potential down to the normal 1.23 volt, but it depresses the potential below this "reversible" value. O was evolved at the anode at potentials of 1.03 and 1.01 in the case of 2 *N*  $H_2SO_4$  electrolyte. In plotting the values, distinct breaks in the curves are discernible at about 1.50 and 1.15 volts. The lowering of the O potential below 1.6 is attributed to the reducing action of the cathodic component of the a. c. upon the  $PtO_2$  produced by the d. c. electrolysis. The Pt oxide which is active between

2.0 and 1.5 volts is a higher oxide than  $PtO_2$  and between 1.5 and 1.23 volts,  $PtO_2$  is the active oxide. Below 1.23 volts it is probable that the reaction  $H_2O_2 + O = H_2O + O_2$  is the cause of the O evolution, the  $H_2O_2$  being produced primarily by the superimposed a. c.

C. G. F.

**Influence of a magnetic field and of mechanical stirring on the electrochemical cell.** T. MASHIMO. *Mem. Coll. Sci. Kyoto Imp. Univ.* 2, 341-7(1917).—A small cell was used containing Pt wire electrodes immersed in 0.5 *M*  $FeCl_3$  soln., and a small enough d. c. current was sent through the cell so that no gas bubbles appeared. Under influence of a magnetic field, a decrease in potential took place, and the effect increased with strength of magnetic field, but finally approached a limit. When each of 2 Fe wire electrodes is separately influenced by a magnetic field, there is a diminution of potential when a strong field is applied or a strong current is sent through the cell. With a weak field or a weak current through the cell, there is a slight increment in which anode is affected. Mechanical stirring of electrolyte near each electrode separately has the same effect as when a magnetic field is applied to that electrode. With a strong current through the cell the drop in potential is most marked when cathode is affected. With a weak cell current there is an increment in potential when stirring is near the anode that is almost equal to drop in potential when cathode is affected. A mere stirring of electrolyte near one electrode gives rise to an e. m. f. between electrodes of the same metal when immersed in its own or other salt solns. as below:

| Electrode. | Solution.             | Potential at disturbed electrode. | Potential at undisturbed electrode. |
|------------|-----------------------|-----------------------------------|-------------------------------------|
| Fe.....    | 0.5 <i>M</i> $FeCl_3$ | +                                 | —                                   |
| Ni.....    | 1 <i>M</i> $FeCl_3$   | +                                 | —                                   |
| Pt.....    | Dil. HCl              | —                                 | +                                   |
| Cu.....    | Dil. HCl              | —                                 | +                                   |

CHAS. H. ELDRIDGE.

**Carbon brushes.** A. T. BARTLETT, *et al.* *Electrician* 82, 97-8(1919).—Discussion of P. Hunter-Brown's paper (*C. A.* 13, 287). Bartlett attributed copper "picking" of the commutator brushes to electrolysis. In an expt. using Cu graphite brushes with high % of Cu it was found after rotating the commutator for 10 hrs. that the surface of the positive brushes was bright coppery whereas that of the neg. brushes was dead black. M. Kahn had found that the voltage drop between collector and brush was comparatively constant over a large range of current density and showed a minimum value below which no current passed, the conditions resembling those in elec. arcs.

C. G. F.

**Some characteristics of transformer oils.** O. H. ESCHHOLZ. *Elec. J.* 16, 74-6 (1919).—A characteristic of hydrocarbons is the formation, on passage of a disruptive charge at or below the oil surface, of gases radically different from the oil vapor. An app. is illustrated for testing the explosibility of oil and gases, and inflammability of the oil vapors. On passing a heavy discharge between the lower pair of electrodes surrounded by hydrocarbon liquid, large quantities of gas evolved at the terminals rise to the surface and diffuse in the air surrounding the upper pair of electrodes. On passing a weak discharge between the upper terminals, a violent explosion results. A heavy short circuit in a transformer will not cause an explosion while a partial short circuit continuing a considerable period at or below the oil surface means accumulation of large quantities of H and consequent liability of explosion. A proper oil level above the terminal boards prevents arcing between exposed conductors and seepage of water over an insulated lead to the oil surface. The hazard in confined oil is due to arcing adjacent the oil surface. The flash and fire points indicate the hazard of spilled oil exposed to a warm temp. A distinction exists between inflammability of gaseous mixts. due to evapn. of oil and explosibility of a mixt. due to disintegration of oil.

W. H. BOYNTON.

**Testing transformer oils.** A. PHILIP. *Electrician* 82, 103(1919).—Minute quantities of  $H_2O$  were detd. in transformer oils by passing a stream of air through the oil in fine bubbles under a pressure of 20-30" of Hg, at the rate of 2-3 bubbles per sec. The air was thus sucked through the oil and passed through U tubes immersed in a mixt. of ice and HCl. The stream of air was passed for 2 hrs., the U tubes were washed, dried, weighed and the wts. of water calcd. The quantities of  $H_2O$  found were 0.006, 0.014, 0.005, 0.017 and 0.0074 g. per 100 cc. of oil. The latter sample was a transformer oil which withstood a test of 22,000 v. before breaking down. After removal of moisture, this oil withstood 28,000 v. Exposure of the oil for 36 hrs. in close proximity to water and subsequent examn. showed no appreciable absorption of water.

W. H. B.

**Notes on the production of continuous electrical oscillations by the three-valve electrode.** E. V. L. APPLETON. *Electrician* 81, 743(1918).—The 3-electrode thermionic valve when functioning as a generator of continuous elec. oscillations may be regarded as a tube having a negative resistance and its action is analogous to the action of the Poulsen arc or the dynatron.

W. E. RUDER.

**The Cottrell processes of electric precipitation, with especial regard to their application to the recovery of potash as a by-product.** J. S. GRASTY. *Manufacturers Record* 74, 70-2(1918); cf. *C. A.* 13, 61.—G. describes the processes, and gives a list of installations with the purposes of each. He points out the need of dust elimination in blast furnace and Portland cement industries as well as the value of the potash recovered therefrom. The cement industry can furnish 100000 tons of  $K_2O$  per annum and the iron industries even more. Statistics are given.

W. H. BOYNTON.

**Humidity correction factor for pentane lamps.** K. TAKATSU AND M. TANAKA. *Elektro-Techn. Laborat. Dept. of Communications Tokyo*, Oct. 1917, Rept. No. 12,

*Sci. Abs.* 21, 106(1918).—A 10 c. p. Harcourt Pentane Lamp certified by the National Physical Laboratories is compared with a 16 c. p. Ediswan-Fleming C-filament standard lamp. An Assmann ventilated hygrometer was used for humidity measure and the observed c. p. of the pentane lamp was corrected for barometric p. From 162 observations, the value of the humidity correction factor was found to be 0.00638. This agrees better with Paterson and Dudding's value of 0.0063 than with Rosa and Crittenden's value of 0.0057. It is suggested that the hood and ventilating duct used by the latter may play a part in causing the difference between the results of the Bureau of Standards and the National Physical Laboratories as the hood affects the c. p. at the same barometric p. and humidity.

RIDGAL, E. K.: *Electrometallurgy: Electrolytic and Electrothermal Processes*. London: Baillière, Tindall and Cox. 247 pp. 7s. 6d. net. For review see *J. Soc. Chem. Ind.* 37, 481R(1918).

**Electrode for galvanic batteries.** W. O. SNELLING. U. S. 1,288,722, Dec. 24. Electrodes for primary batteries are formed of granular C 49.5, granular  $MnO_2$  49.5 and finely divided metallic Ni 0.5 parts. These electrodes are designed for use with cells of the Leclanché type. The Ni increases the efficiency of the depolarizing action, as do also Ni or Fe oxides, Pt or Pd.

**Electric gravity-battery.** D. H. WILSON. U. S. 1,289,030, Dec. 24. The pat. relates to structural features of a battery with Zn and Cu electrodes.

**Galvanic batteries.** CHLORIDE ELEC. STORAGE CO. and B. HEAP. Brit. 121,188, Dec. 6, 1917. Wood separators are treated in a weak alk. soln., washed in  $H_2O$ , and dried in a vacuum chamber heated by steam otherwise. The alk. soln. may consist of a soln. of NaOH of sp. gr. 1.05, the period of immersion being 24 hrs. or less if the soln. is heated and used under pressure. The separators are made of American cypress or other wood of the same genus, such as California red wood.

**Electrolytic production of magnesium.** G. O. SEWARD. Brit. 120,908, Nov. 11, 1918. A fused electrolyte containing  $MgF_2$  carries a quantity of  $MgO$  in considerable excess of that sol. therein, and is of sufficient d. to prevent rapid subsidence of the undissolved oxide. The sp. gr. should exceed 3, and is preferably about 4. The electrolyte may contain fluorides of metals electropositive to Mg and salts which increase the d. and lower the m. p. A suitable mixt. contains 55 parts  $MgF_2$ , 5 parts NaF, and 40 parts  $BaF_2$ . The temp. of electrolysis may be 900–1000°, and the current d. at the cathode 400 amp. per sq. ft. A suitable cell comprizes a cast-Fe container cooled at the base and encrusted with solid electrolyte, the cathode or cathodes, preferably of cast Fe and with edges or points, projecting through the base. C anodes depend into the electrolyte. Above the cathode is a cooling coil which produces a crust sufficient to shield the floating Mg from the air but easily broken when the metal is to be removed. On the electrolyte floats a layer of  $MgO$  or  $MgCO_3$ , part of the oxide becoming suspended and combining with the F. This layer also protects the anodes.

**Electric furnace for ore reduction.** L. G. ROWAND. U. S. 1,289,056, Dec. 24.

**Electric resistance furnace adapted for reducing zinc ores.** L. G. ROWAND. U. S. 1,289,055, Dec. 24.

## 5. PHOTOGRAPHY.

LOUIS DERR.

**Gum dichromate process with a new colloid.** H. S. STARNES. *Phot. J.* 58, 287-93(1918).—Gum senegal is preferable to gum arabic, being softer, less brittle, and more under control. The sensitizing soln. is 50%  $\text{Na}_2\text{Cr}_2\text{O}_7$ , and the exposure about one-eighth that of printing-out paper; an actinometer must be used. For development the print is soaked 1 min. in water, then flooded in a bath made of 6% HCl in satd. alum soln., dild. to 16 times its bulk. The high lights float away in a few sec., and development is completed with a jet of water from a small nozzle. L. DERR.

**Causes of variation in the Watkins factor for different developers.** J. C. KINGDON. *Phot. J.* 58, 270-80(1918).—The rate of diffusion of different developers was studied by expts. on strips of bromide paper in gelatin jelly. As the blackening progressed there was always at its edge a narrow zone of color, usually red, merging into the advancing black area, and suggesting that the reaction forming it is effected by a developer more dil. than that which effects complete reduction; and from this it appears that a certain concn. of developer is required for complete reduction. With amidol this critical concn. is represented by a normal developer dild. more than 100-fold but probably less than 1000-fold. The increased rapidity of development with rise of temp. is claimed not to be due to increased rapidity of chem. action, but to the faster travel of the zone of critical concn. through the gelatin. From this it follows that the time of appearance of the image will be longer for a developer in which relatively high mol. concn. is needed to effect development. Since the difference in rates of diffusion is not large, the total time required for complete development will be nearly the same for all developers—a familiar fact. Hence the critical concn. is in inverse proportion to the Watkins factors. L. DERR.

**Stripping films.** E. G. *Rev. sci.* 56, 244-5(1918).—The manipulation required to detach a photographic film from its support varies according to the necessity of keeping the original dimensions or of enlarging them. In the first case, the plate may be soaked 15-20 min. in a bath containing 5 g.  $\text{Na}_2\text{CO}_3$  and 20 cc. commercial formalin in 100 cc. water, then dried without washing. The film is then cut through with a knife 2-3 mm. from the edges, and a bath of 10% HCl follows. This liberates fine bubbles of  $\text{CO}_2$  which lift the film from its support. The temporary support, a glass plate carefully cleaned with talc and coated with collodion, is slid under the film, and the plate is dried and coated with 3% collodion contg. a little castor oil. The film when dry is easily detached and is thus protected by the collodion on both faces. To obtain a film of enlarged size, it is enough to omit the formalin from the bath given. A single bath of 10% HCl will usually effect the result, but is uncertain; 10%  $\text{NH}_4\text{F}$  is preferable if a single bath must be used, but the film is then very tenuous. L. D.

**Utilization of old bromide paper.** E. C. *Rev. sci.* 56, 528-9(1918).—If the paper has not been fogged by exposure to light, it should be given a preliminary exposure to diffused light for 1-2 sec., then immersed 5-6 min. in 3%  $\text{K}_2\text{Cr}_2\text{O}_7$  or 8%  $\text{CuSO}_4$ , with a thorough 30-min. wash afterwards. If the paper is very old or fogged, the bath should be 3 g. NaCl and 8 g.  $\text{CuSO}_4$  in 100 cc. water. As these baths increase contrast, they afford a method for converting soft-printing papers into contrast-giving ones. L. D.

**Mechanism of Light-Action on photographic plates; new theory of the development of the latent image.** A. M. CHANOS. *Rev. sci.* 56, 557-8(1918).—Three phases of the action of the developing bath are distinguished: (1) penetration, in which the developer reaches the AgBr grains; (2) reduction, corresponding to the principal reactions which give metallic Ag; (3) precipitation, answering to the appearance of Ag

in grains of visible size, and their growth. The developer dissolves and ionizes the AgBr grains only partly altered by the light, and discharges the Ag ions by the electrons of the soln., thus producing metallic Ag which remains in colloidal soln. The fully exposed AgBr grains act as condensation nuclei, ppt. the colloidal Ag upon themselves, and thus give the black Ag aggregates of the image. These aggregates may attain a vol. which is independent of the exposure the plate has received. L. DERR.

## 6. INORGANIC CHEMISTRY.

---

H. I. SCHLESINGER.

**Action of chlorine on alkali iodides.** W. N. RAE. *J. Chem. Soc.* 113, 880-4 (1918); cf. *C. A.* 9, 3182.—A slow stream of dry  $\text{Cl}_2$  was passed over small amts. of the carefully dried salts contained in weighing bottles until const. wt. was reached. In all cases  $\text{MICl}_4$  appeared to be formed; the increase of wt.-time curves showed no break corresponding to formation of the more stable  $\text{MICl}_3$ . The stability of the compds. proved to be the reverse of their rate of formation. An immediate increase in the rate of formation followed introduction of a trace of water. All the compds. are yellow powders, the color showing a marked gradation with at. wt. of the metal; the Cs compd. is mustard-yellow, that of Li a deep orange. A. R. MIDDLETON.

**Preparation of hypophosphates.** R. G. VANNAME AND W. J. HUFF. *Am. J. Sci.* 46, 587-90(1918).—A modification of the method of Salzer (*Ann.* 211, 1(1882)) is described. Sticks of P about  $3.5 \times 0.65$  in., cast upon glass rods, are suspended in  $\text{Na}_2\text{CO}_3$  soln., 250 g. per liter, so that less than 1 cm. emerges. The rods are adjusted as the exposed P oxidizes and dissolves. When the soln. becomes acid to Congo Red, the rods and holder are transferred to another vessel of fresh soln. The yields are 10-16% of the theory. Neutralization of 250 g. carbonate requires usually 7-10 days; complete oxidation of the sticks of P require 8-9 weeks. A. R. MIDDLETON.

**Carbides of rare earths of the cerium group.** A. DAMIENS. *Ann. chim.* 10, 137-83(1918); cf. *C. A.* 7, 3578, 3932.—This article is a very detailed account of the investigations previously reported together with additional matter. In addition to an extended historical résumé, full details are given of the prepn. and analysis of the carbides and their metallographic investigation, and the analysis of the complex gas mixts. resulting from the action of water upon them. For these methods see *C. A.* 7, 1338, 1468. Some of the data obtained are shown in the following table:

| Carbide                                     | CaCe.                    |             |                                  | CaLa.                    | CaNd.                    | CaPr.                    | CaSa.                    |                          |

The speed of decompn. of the carbide increases with the content of graphite; complete decompn. of the CaSa with 0.49% required several days, that with 2.51% only a few minutes. The formation of the hydroxides M(OH)<sub>3</sub> in all cases was rigorously proved. Ce(OH)<sub>3</sub>, which has not previously been described, is white and fixes O in the cold with evolution of heat and formation of Ce(OH)<sub>4</sub>. The O absorbed was always 6-7% greater than the theoretical; this was finally traced to absorption of O by small amts. of liquid unsatd. hydrocarbons retained in the hydroxide. A special app. was devised to permit washing *in vacuo* with EtOH and Et<sub>2</sub>O; the O absorbed was then nearly the theoretical amt. Polished surfaces of the carbides are altered by moisture too quickly to permit microscopical examn. Fragments were imbedded in softened shellac in brass cylinders of 20 mm. diameter so as to leave a portion projecting above the edge of the cylinder. A plane surface was rough ground on emery papers of increasing fineness and polished on felt treated with a pommade of dry vaseline and fine Al powder. The greasy surface remained unaltered for some moments. On a cover glass of the diameter of the cylinder was placed a drop of Canada balsam to which 0.1 its wt. of anhydrous xylene had been added; the greasy surface was quickly rubbed clean on dry felt and fixed in the balsam. Specimens thus prepd. remained unaltered more than a year. The graphitic carbides showed golden yellow polished surfaces. They were homogeneous and perfectly crystd.

A. R. MIDDLETON.

**New complex base of osmium.** L. CHUGAEV. *Bull. soc. chim.* 23, 377-9(1918).

—An aq. soln. of 1 g. Na<sub>2</sub>OsCl<sub>6</sub> and 1.5 g. thiourea acidified with HCl was boiled for some min., filtered while lukewarm, cooled and concd. HCl and solid LiCl in excess were added to increase to the utmost Cl'. A mixt. of two cryst. compds. sepd. differing decidedly in soly. in EtOH. The present paper deals only with the more sol. This was obtained pure by extg. the mixt. with cold 95% EtOH, pptg. by an equal vol. of Et<sub>2</sub>O. The compd. ppts. in sq. tables brownish red with metallic reflection, easily sol. in water forming a fine, intense red soln. Analysis indicated a compn. corresponding to [Os(NH<sub>2</sub>CSNH<sub>2</sub>)<sub>4</sub>]Cl<sub>4</sub>.H<sub>2</sub>O. The water is lost at 125°. Cryoscopic and cond. measurements both indicated 4 ions in aq. soln. A series of red salts is obtained by double decompn., most of which are very sol. in water; much less sol. are the chlorosmate, chlororhodite, chloroiridite, ferro- and ferricyanide. These salts are not described.

A. R. MIDDLETON.

**Hydroxylamine platinum bases.** L. A. CHUGAEV AND I. I. CHERNYAEV. *J. Chem. Soc.* 113, 884-97(1918).—Like NH<sub>3</sub>, NH<sub>2</sub>OH combines with platinum salts to form complex compds. fairly closely analogous to the platinoammines. It can also replace NH<sub>3</sub> to form a series of mixed compds., [Pt(NH<sub>2</sub>OH)<sub>n</sub>(NH<sub>3</sub>)<sub>4-n</sub>]X<sub>2</sub>. Of the six theoretically possible, *vis.*, I, [Pt(NH<sub>2</sub>OH)<sub>4</sub>]X<sub>2</sub>, II, [Pt(NH<sub>2</sub>OH)<sub>3</sub>NH<sub>3</sub>]X<sub>2</sub>, IIIa, *trans*-[Pt(NH<sub>2</sub>OH)<sub>2</sub>(NH<sub>3</sub>)<sub>2</sub>]X<sub>2</sub>, IIIb, *cis*-[Pt(NH<sub>2</sub>OH)<sub>2</sub>(NH<sub>3</sub>)<sub>2</sub>]X<sub>2</sub>, IV, [Pt(NH<sub>2</sub>OH)(NH<sub>3</sub>)<sub>3</sub>]X<sub>2</sub>, V, [Pt(NH<sub>3</sub>)<sub>4</sub>]X<sub>2</sub>, I, IIIa and V have been described. The prepn. and proper-

ties of the remaining three are here described together with the reactions from which their constitution is inferred. *Cis-diamminodihydroxylaminoplatinous chloride*, (IIIa,  $X = Cl$ ), was obtained by heating 1 g. of Peyrone's chloride, *cis*- $[Pt(NH_3)_2Cl_2]Cl_2$  with 0.6 g.  $NH_2OH \cdot HCl$ , 3.5 cc.  $NaOH$  10% soln. and 7 cc. water with frequent shaking to complete soln. On cooling colorless needles sepd. which were recrystd. from dil.  $HCl$ . The salt is readily sol. in water and the  $Cl$  is completely ionized. It forms a very characteristic *chloroplatinite*  $[IIIb]PtCl_4$ , rose-violet needles, sol. in water, which with the chloride of Reiset's Base I,  $[V]Cl_3$ , gave the insol. green Magnus's salt,  $[Pt(NH_3)_4]PtCl_4$ ; also a *chloropalladiite*,  $[IIIb]PdCl_4$ , dirty green, micro-cryst. powder was prepd. The *trans*-isomer was also prepd. in the same manner from the chloride of Reiset's Base II,  $[Pt(NH_3)_2Cl_2]Cl_2$ . The work of Alexander (*Ann.* 246, 239(1893)) was repeated and corrections are noted. A mixed salt (VI) *trans-dichloroamminohydroxylaminoplatinum*,  $[Pt(NH_3)(NH_2OH)Cl_2]$ , was obtained by heating 1 g. of the *cis*-chloride with 25 cc. dil. (1:4)  $HCl$  on the water bath for 1.5 hrs. It forms yellow, dentate crystals, sparingly sol. in cold water, more largely in hot, very sparingly sol. in  $EtOH$ . The  $Cl$  is totally un-ionized upon first soln., but becomes ionic slowly on standing, rapidly on heating. Prolonged action of hot  $HCl$  gives Cossa's acid,  $H[Pt(NH_3)Cl_3]$ , which was identified by pptn. with the chloride of Reiset's Base I, which gave the characteristic orange-yellow scales of Cossa's salt,  $[Pt(NH_3)Cl_3]_2[Pt(NH_3)_4]$ . *Triamminohydroxylaminoplatinous chloride*,  $[IV]Cl_3$ , was obtained by action of anhydrous liquid  $NH_3$  on the mixed salt (VI) in a sealed tube at room temp. as a white cryst. powder; recrystd. from 80%  $EtOH$  in glistening plates, readily sol. in water. Heated with  $HCl$  it gives Cleve's salt,  $[Pt(NH_3)_4]Cl_3$  detected by its characteristic platinochloride. The *chloroplatinite* of  $[IV]$ , obtained by pptg. the chloride with  $K_2PtCl_4$ , is a pale green powder which can be recrystd. from hot water. *Amminotrihydroxylaminoplatinous chloride*,  $[II]Cl_3$ , was prepd. by heating the mixed chloride (VI) with the theoretical quantities of  $NH_2OH \cdot HCl$  and  $NaOH$  in aq. soln. It is very sol. in water but is pptd. by addition of  $EtOH$  or  $HCl$ . Its *chloroplatinite* forms rose-violet needles; the *chloropalladiite*, red-violet needles. *Trans-dichlorodihydroxylaminoplatinum*,  $[Pt(NH_2OH)_2Cl_2]$ , (A), as stated by Alexander, readily obtained by heating  $[Pt(NH_2OH)_4]Cl_3$  with dil.  $HCl$ , was found to form double chlorides with certain chlorides; with the chloride of Reiset's Base I,  $[Pt(NH_3)_4][Pt(NH_2OH)_2Cl_4] \cdot 2H_2O$ , pale yellow prismatic crystals, readily sol. in water; with  $CsCl$ ,  $Cs_2[Pt(NH_2OH)_2Cl_4]$ , having the same appearance and properties. In these compds. an unstable complex anion appears to be formed by union of the non-electrolyte with two  $Cl$  ions. *Trans-dipyridinodihydroxylaminoplatinous chloride* was obtained by dissolving (A) in pyridine; the orange soln. rapidly loses color and a colorless cryst. powder seps. Its *chloroplatinite* forms pale rose prisms. With  $HCl$  the chloride behaves like the corresponding ammino compd. A. R. M.

Action of hydrogen sulfide on mercuric bromide. GIAMBATTISTA FRANCESCHI. Bologna. *Boll. chim. farm.* 57, 221-3(1918).—When several drops of a pure alc. soln. of  $H_2S$  were added to an alc. soln. of  $HgBr_2$  (free from  $Hg_2Br_2$ ) there was at once produced a white turbidity with subsequent pptn. of  $Hg_2Br_2$ . When the alc. soln. of  $H_2S$  was added in greater amt., but not in excess, to an alc. soln. of  $HgBr_2$  there was produced a canary-yellow color with subsequent pptn. of a substance of the same color which proved to have the compn.  $2 HgS \cdot HgBr_2$ ; the formula of the latter may be represented as  $Hg(SHgBr)_2$ . When  $H_2S$  was added in excess a black ppt. of  $HgS$  was produced. The above 3 successive reactions may be represented as follows: (1)  $H_2S + 2HgBr_2 = Hg_2Br_2 + S + 2HBr$ ; (2)  $H_2S + 3Hg_2Br_2 + 3S = 2(2HgS \cdot HgBr_2) + 2HBr$ ; (3)  $H_2S + HgS \cdot HgBr_2 = 2HgS + 2HBr$ . H. S. PAINE.

Influence of some nitrogen derivatives on the conductivity of boric acid (BÖSEKEN, *et al.*) 10. Salts of the complex acid, pyrocatechol-boric acid (BÖSEKEN, *et al.*) 10.

## 7. ANALYTICAL CHEMISTRY.

E. G. R. ARDAUGH.

The rapid determination of nitric acid. L. MAUGÉ. *l'Industrie chimique* 5, 255-6(1918).—In controlling many commercial processes it is desirable to have a rapid and accurate method for detg.  $\text{HNO}_3$ . In estg. the degree of denitration which sulfonitric mixts. have undergone, satisfactory results have been obtained by a method based on the reaction between  $\text{FeSO}_4$  and  $\text{HNO}_3$ . In concd.  $\text{H}_2\text{SO}_4$  soln.  $\text{FeSO}_4$  gives a brown coloration with small amts. of  $\text{HNO}_3$ ; if more  $\text{HNO}_3$  is added, a point is reached at which the brown coloration is suddenly discharged. This phenomenon appears to be const. When cc.  $\text{FeSO}_4$  mixt. are plotted against %  $\text{HNO}_3$ , a hyperbolic curve results. The brown coloration is produced by the formation of  $2\text{FeSO}_4\text{NO}$ . The final discharge of the color is due to oxidation of the  $\text{Fe}^+$  when the  $\text{HNO}_3$  content is sufficiently great.  $6\text{FeSO}_4 + 3\text{H}_2\text{SO}_4 + 2\text{HNO}_3 \rightarrow 3\text{Fe}_2(\text{SO}_4)_3 + 4\text{H}_2\text{O} + 2\text{NO}$ . Hence, 1 g.  $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$  is decolorized by 0.075 g.  $\text{HNO}_3$ . A satisfactory standard soln. contains 66.66 g.  $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$  per l. Into a glass provided with a foot base, measure 10 cc.  $\text{FeSO}_4$  soln., add, with shaking, 50 cc. concd.  $\text{H}_2\text{SO}_4$  (60-66° Bé.). Add from a buret the mixt. to be examined. Shake constantly and add a soln. gradually, at a more or less rapid rate depending on the content of  $\text{HNO}_3$ . The brown coloration may become almost black. Continue the addition until the color is just discharged. To prepare the standard soln., dissolve 67 g. cryst.  $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$  in 1 l.  $\text{H}_2\text{O}$ ; titrate with  $\text{KMnO}_4$  and calc. the diln. necessary to bring to exact concn. 66.66 g.  $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$  per l. Stabilize by adding about 10 cc.  $\text{H}_2\text{SO}_4$  to the  $\text{H}_2\text{O}$ . A layer of paraffin oil will partially protect from nitric fumes, but in spite of these precautions the soln. must be prepared fresh from time to time. Graphs assist in making rapid calcns. from the measurements.

H. M. LANCASTER.

Volumetric estimation of the sulfon. R. HOWDEN. *Chem. News* 117, 383(1918).—To the sulfate soln. (e. g.,  $\text{Na}_2\text{SO}_4$ ), add an excess of  $\text{Na}_2\text{CO}_3$  to ppt. Ca or heavy metals and filter; render the filtrate neutral to Me-orange, and add a few drops of phenolphthalein soln. and an excess of pure pptd.  $\text{BaCO}_3$  shaken up with  $\text{H}_2\text{O}$ . Titrate with 0.1 N  $\text{HCl}$  till the red color just vanishes. This requires somewhat more than half the theoretical amt. of acid, and furnishes a fair approximation to the amt. of  $\text{SO}_4$  present. To obtain a more exact result, filter off the insol. Ba salts and wash the filter, and titrate the filtrate, using Me-orange as indicator. (The mixt. may be made up to vol., mixed, filtered, and an aliquot titrated.) The soln. contains both Ba and  $\text{SO}_4$ , but the 2 sources of error are compensatory.

F. W. SMITHER.

A new general method of determining iodine in inorganic and organic compounds. N. TARUGI. *Pisa. Gazz. chim. ital* 48, I, 1-16(1918).—The work described arose out of the necessity of detg. I in aq. solns. of  $\text{ICl}_3$  proposed and used as a sterilizer of  $\text{H}_2\text{O}$  (T. and Bracci, *Igiene moderna* 8, No. 5). The vague instructions found in the literature were of little use in detg.  $\text{ICl}$  and  $\text{ICl}_3$  accurately in aq. solns.  $\text{ICl}_3$  in aq. solns. above 27% in concn. keeps its titer unchanged in colored glass vessels if protected from dust. The dissociation of  $\text{ICl}_3$  into  $\text{ICl} + \text{Cl}_2$  that takes place in the solid state and completely above 25° is very slight in concd. solns. The  $\text{Cl}$  liberated in the 1st phase stops the dissociation and  $\text{HCl}$  that would be formed by hydrolysis also stops the dissociation of  $\text{ICl}_3$ . Freshly prepd.  $\text{ICl}_3$  contains a small excess of  $\text{Cl}$  and this stabilizes the soln. Pure  $\text{ICl}_3$  showed a diminution of active  $\text{Cl}$  and therefore the formation of some  $\text{ICl} + \text{HCl}$ . The soln. then remained unchanged. In concd. solns. the reaction  $5\text{ICl} + 3\text{H}_2\text{O} \rightleftharpoons \text{HIO}_3 + 5\text{HCl} + 4\text{I}$  apparently proceeds backward. In fact the addition of  $\text{HIO}_3$  to a soln. whose titer has become const. produces an increase in the active halogen content. That  $\text{Cl}$  and  $\text{HCl}$  stabilize  $\text{ICl}_3$  soln. is also shown

thus: if a drop of carbonate or  $\text{Na}_2\text{S}_2\text{O}_3$  soln. is added to a concd. soln. of  $\text{ICl}_3$  containing Cl or HCl the fugitive brown of I appears at once, *i. e.*,  $5\text{ICl}_3 + 3\text{H}_2\text{O} \longrightarrow \text{HIO}_3 + 4\text{I} + 5\text{HCl}$  takes place. The  $\text{ICl}_3$  was prepd. as follows: 26.68 g. pure I suspended in 80 cc. distd.  $\text{H}_2\text{O}$  were treated with Cl as long as this was absorbed (24.2 g.) and the whole was dild. to 100 cc. Expts. on the detn. of the 2 halogens separately by reducing with Al (pieces and powder) and extg. the  $\text{I}_2$  formed with  $\text{CHCl}_3$  were not quant. but are fully described. The following reaction was successful:  $6\text{FeSO}_4 + 3\text{H}_2\text{SO}_4 + 2\text{ICl}_3 \longrightarrow 3\text{Fe}_2(\text{SO}_4)_3 + 2\text{I} + 6\text{HCl}$ . The  $\text{FeSO}_4$  soln. was best prepd. by dissolving 14 g. cryst.  $\text{FeSO}_4$  in 100 cc.  $\text{H}_2\text{O}$  and adding 100 cc. 2 N  $\text{H}_2\text{SO}_4$ . This soln. was titrated with  $\text{KMnO}_4$ . A known vol. of the  $\text{ICl}_3$  soln. was placed in a separatory funnel and 25 cc. of the titrated  $\text{FeSO}_4$  soln. added. The mixt. was agitated and allowed to stand 1.5 hrs. The soln. is extd. repeatedly with  $\text{CHCl}_3$  until it becomes colorless. The  $\text{CHCl}_3$  ext. is collected in another separatory funnel and washed with  $\text{H}_2\text{O}$ . The wash  $\text{H}_2\text{O}$  is extd. with fresh  $\text{CHCl}_3$  until colorless. The entire  $\text{CHCl}_3$  ext. is then mixed with an equal vol. of  $\text{H}_2\text{O}$  and titrated for I with  $\text{Na}_2\text{S}_2\text{O}_3$ . The aq. residue from the extn. was filtered and the  $\text{FeSO}_4$  remaining detd. with  $\text{KMnO}_4$ . This gave data from which the Cl could be calcd. Tabulated results on blank expts. with pure  $\text{ICl}_3$  showed perfect data for both the I and Cl detns. In order to det. the amts. of  $\text{ICl}$  and  $\text{ICl}_3$ , resp., present in a mixt. the I and Cl are detd. as stated and from the numerical ratio I:Cl and a table given in the original the amt. of each present is readily detd. A ratio greater than 1.192 indicates that the soln. is  $\text{ICl}_3$  containing excess Cl. A table of densities of  $\text{ICl}_3$  solns. and the %  $\text{ICl}_3$  present by wt. and by vol. is given. The method being so convenient T. has extended it to the detn. of I in other compds. In order to det. I in inorg. compds. the compd. in question is placed in  $\text{H}_2\text{O}$ , cooled in an ice bath and treated with Cl until the presence of excess Cl is evident. The liquid is then dild. to a definite vol. An aliquot portion of the soln. is now taken and treated as above. The  $\text{Na}_2\text{S}_2\text{O}_3$  titration of the  $\text{CHCl}_3$  soln. gives the data sought. With oxygenated compds. an equal wt. of  $\text{NaHSO}_4$  is added to the sample before treating as described above. In the case of  $\text{HIO}_3$  and its salts the detn. with  $\text{FeSO}_4$  can be made directly.  $\text{EtI}$  and  $\text{CHI}_3$  may be converted into  $\text{ICl}_3$  by treating with Cl in  $\text{H}_2\text{O}$  soln. Most org. compds., however, require the following treatment: The compd. is placed in a tubulated retort arranged so that the elongated tube dips into a receiver packed in ice containing 10 cc.  $\text{H}_2\text{O}$ . Five to ten cc.  $\text{H}_2\text{SO}_4$  is introduced with the sample and gradually heated to boiling while a stream of Cl is passed. Care is taken to minimize the contact of Cl and stoppers and connections. This treatment was satisfactory for 11 org. compds. tried. Expts. on the detn. of I in urine when known amts. of KI were dissolved gave satisfactory results. Gravimetric detns. gave the same data as those obtained with this method in urine of patients taking iodides. E. J. WITZEMANN.

**The analysis of aluminium alloys and metallic aluminium.** J. J. FOX, E. W. SKELTON AND F. R. ENNOS. *J. Soc. Chem. Ind.* 37, 328-33T(1918).—In order to combine speed and accuracy in analytical processes for these alloys, the method selected must be specially adapted for the particular type of alloy under examn. For the purpose of analysis three types are distinguished: *Type 1*: Unalloyed Al. The examn. in this case is for all metallic impurities and for Si. Since any single impurity in metallic Al rarely exceeds 1%, the main impurities should be detd. to within  $\pm 0.05\%$ . The detn. of the lesser impurities should be subject to a much smaller error. *Type 2*: Comprizes alloys containing up to 13% Cu and Zn up to 3%. If Sn is present it is usually less than 3%; Mn, Ni, Mg may occur. All these constituents should be detd. to at least within  $\pm 0.1\%$  and generally more accurately. Impurities and constituents such as Fe, Pb and Si should be detd. to at least 0.05%. *Type 3*: Includes alloys containing up to 20% Zn, Cu up to 5% and all other constituents not exceeding 1%.

The Zn in such cases should certainly be detd. within 0.2% and generally within  $\pm 0.1\%$ . A rapid qual. test should be made in order to det. to which of the three classes the metal belongs. Details are given for the detn. of the following: Pb, Mn, Si, Cu, Sn, Fe, Zn, Mg, Ni. Electrolytic methods for Cu, Fe and Zn are special features. Electrolysis of Cu solns. in presence of  $H_2O_2$  gives results which seldom differ by more than  $\pm 0.03\%$  on a 3% Cu content. Using a Au-plated Pt cathode, Fe and Zn are pptd. together. The working details are too numerous and elaborate to admit of satisfactory abstracting.

H. M. LANCASTER.

**Analysis of hard alloys of aluminium.** A. TRAVERS. *Chimie et industrie*. 1, 708-11 (1918).—The alloys referred to are light alloys composed of an Al base with comparatively small amts. of certain other metals which impart interesting mechanical properties. They commonly show 1-5% Cu, 0.3-1% Mg, 2-8% Zn, traces of Fe and Zn amtg. to about 0.5%. Traces of Si may come from the crucibles. In some alloys the Cu is replaced by Ni and Co. The methods given are essentially works laboratory methods, and are remarkably rapid. In 4-5 hrs. an analyst det. Zn, Mg and Fe. A 2nd operator may meanwhile obtain the figures for Cu and Mn in less than 30 min. An attempt to reproduce working details in an abstract would lead to failure, but the following points are noted as special features: A 2 g. portion of the alloy is attacked with a soln. of 15 g. NaOH containing about 20 cc.  $N Na_2CO_3$ . This treatment dissolves Al and Zn, leaving other metals (except Mn) as a residue. The Zn is then sepd. from Al by  $Na_2S$ , the Al remaining in soln. as  $Al(ONa)_3$ . The Zn is finally pptd. as  $ZnNH_4PO_4$  and titrated with 0.2  $N H_2SO_4$  using Me-orange as indicator. The persulfate method for Mn is applied to a special test portion, Al is detd. in the filtrate from the  $ZnS$  containing the Al as  $Al(ONa)_3$ . After removing  $H_2S$  by boiling, apply Stock's method, using a mixt. of KI +  $KIO_3$ . As the light alloys contain only traces of Fe, there is no interference at this point because of Fe. The little Fe present is found in the original insol. residue and can be detd. by means of  $TiCl_3$ . The Mg is first pptd. as  $MgNH_4PO_4$ , using EtOH to complete the sepn. The ppt. is then titrated with standard  $H_2SO_4$ . The detn. of Cu is carried out preferably on a sep. portion of alloy, using the iodide method, if the Cu content is greater than 1%. It is necessary to remove or correct for Fe. If Cu content is less than 1% the colorimetric method is preferred ( $NH_4OH$ , excluding  $NH_4$  salts). The accuracy claimed for this is 0.100%. If Ni is detd. use dimethylglyoxime in presence of tartaric acid. If Co is present and is to be estd. the nitroso- $\beta$ -naphthol method is recommended. H. M. LANCASTER.

**Analysis of ferromanganese.** L. R. TAYLOR. *Chem. Met. Eng.* 20, 53 (1919).—(1) Dissolve 1 g. in 50 cc.  $HNO_3$  (d. 1.13) by boiling gently in a covered beaker for about 30 min.; transfer to a 1. flask, make up to mark and mix, pipet out 25 cc. and det. Mn by the bismuthate method. (2) Treat 0.5 g. of the sample in a casserole with 50 cc.  $HNO_3$  (d. 1.13), evap. to dryness, and ignite over a free flame. Cool, take up with HCl, evap. to dryness, and bake for a few min. at a low temp.; take up with dil. HCl, boil, and filter. Det. Fe in the filtrate by titration with 0.1  $N KMnO_4$ . Ignite the residue, weigh  $SiO_2$ , and calc. to Si (if Si is over 1%, the  $SiO_2$  is treated with HF and  $H_2SO_4$ ). (3) Treat 1.63 g. of the sample as for Fe and Si. After evapp. to dryness with HCl, add just enough HCl to dissolve the residue. Warm, add 20 cc.  $HNO_3$ , and evap. to a sirupy consistency, and repeat this evapn. with  $HNO_3$ . Then add 20 cc.  $HNO_3$ , evap. to about 12 cc., dil. to about 100 cc. with hot  $H_2O$  and cool to 65-75°, filter into a 250-cc. erlenmeyer, and add 60 cc. of filtered  $MoO_3$  soln. Shake for a few min., let stand in a warm place for about 1 hr., filter on a weighed gooch, wash with 3%  $HNO_3$  soln., dry, and weigh (each mg. = 0.001% P). F. W. SMITHER.

**Sampling brass ashes.** H. W. C. *Metal Ind.* 17, 14 (1919).—While the ashes are being loaded into trucks or carts take a shovelful from each barrow, thoroughly

mix the sample and quarter down until from 2 to 10 cwt. (according to size of the lot) result. Grind in a mortar or on a plate, mix and det.  $H_2O$  on a 1-lb. sample. Dry about 7 lbs., weigh out 5 lbs. of the dried material, and crush until every particle except the metallics passes through a 30-mesh sieve; any pieces of Zn, Pb, or Fe are picked out, weighed, and their exact wt. of pure, dry sand is added to the fines. Mix the fines, and make up 3 packets (about 4 oz. each); inside of each place a small packet made up of chippings from the metallics. The 3 packets are sealed in the presence of the buyer's and seller's representatives, and each takes one for assay, the third being reserved for a referee if necessary. The label states the wt., date, amt. of  $H_2O$ , and % of fines and metallics. All mill sweepings and such like residues are burnt to get rid of waste, paper, oil, etc., then riddled through a  $\frac{1}{2}$  in. riddle to remove pieces of brass, Cu and Fe, and the fine material is sampled.

F. W. SMITHER.

**The determination of cadmium by the hydrogen sulfide method.** EDWARD SCHRAMM. *J. Ind. Eng. Chem.* 11, 110-3(1919).—A method is described for the detn. of Cd in brasses when pptd. by  $H_2S$ . S. states in his summary that "because of the mass of salts present, the pptn. with  $H_2S$  must be made in a somewhat larger vol. than the later pptns.; it may sometimes happen, if the concn. of H ion is too small, that some Zn may come down with the 3rd ppt. of CdS. Finally, it must be remembered that CdS is insol. in a soln. containing 2-3%  $H_2SO_4$ , only when the soln. is satd. with  $H_2S$ ."  $NH_4$  salts tend to prevent CdS from entering the colloidal state. ERLE M. BILLINGS.

**The determination of phosphorus in vanadium steels, ferrovanadium, non-vanadium steels, and pig iron.** CHAS. MORRIS JOHNSON. *J. Ind. Eng. Chem.* 11, 113-6(1919).—A series of methods are described for the detn. of P (1) in steel containing V up to 2.6%, (2) in U. S. standard steels and pig irons to which have been added 28% V and in ferrovanadium containing 56.7% V, (3) in non-V steels and pig Fe. In all of these methods an ammoniacal water soln. of  $(NH_4)_2MoO_4$  is used in place of the acid molybdate. Simplicity of prepn., ease of handling, and const. pptg. power are claimed for the soln. To avoid low results sufficient  $HNO_3$  must be present.

ERLE M. BILLINGS.

**Pregl micro-determination of nitrogen.** HANS FISCHER. *Inst. angew. med. Chem. Innsbruck. Ber.* 51, 1322-5(1918).—Wishing to learn if it might not be possible to substitute for Pregl's method (*Die quantitative organische Mikroanalyse*, Springer, 1917) the ordinary Dumas method on a reduced scale, F., like Dubsky (*Vereinfachte quantitative Mikro-Elementaranalyse organischer Substanzen*, Veit, 1917), attempted to do so, using  $NaHCO_3$  as the source of  $CO_2$  and a Cu spiral at the end of the tube. For a long time satisfactory results were obtained until in a systematic study of substances especially difficult to burn the results began to become uncertain; P.'s method was now followed exactly and at once the trouble stopped. There are 2 sources of error in the first method: (1) Even with  $NaHCO_3$  it is not always possible to keep the bubbles of  $CO_2$  as small as is necessary; (2) as pointed out by P., when a Cu spiral is used at the end of the tube instead of CuO and it is heated a non-absorbable gas is given off. A table of the results obtained with 3-7 mg. samples of various compds. by the 2 methods is given. The P. method is also more sensitive than the Lassaing test for the qual. detection of N in small amts.

CHAS. A. ROULLER.

**The detection and determination of nitroso- $\beta$ -naphthol.** PAUL NICOLARDOT AND LUCIEN VALLI-DOUAU. *Bull. soc. chim.* 23, 455-9(1918).—The extn. by  $Et_2O$  of nitroso- $\beta$ -naphthol (a) from its  $H_2O$  soln. and evapn. to dryness of the  $Et_2O$  ext. is inaccurate since the impurities are also sol. A table shows how substances like AcOH increase the soly. of (a) in  $H_2O$ , thereby modifying the titration of the soln. Titration of an EtOH soln. of (a) with  $CuSO_4$  soln., using  $K_4Fe(CN)_6$  as an indicator is accurate only to about 10%. (a) forms 2 metallic complexes:  $(C_6H_4ONO)_2Co$  and  $(C_6H_4-$

$\text{ONO}_2\text{Fe}$ . Use of the former introduces errors of 5% by the simultaneous formation of another complex,  $(\text{C}_{10}\text{H}_8\text{ONO})_2\text{Co}$ . The following volumetric method is described: Dissolve 1 g. of purified (a) in 50 cc. distd.  $\text{Me}_2\text{CO}$ , add 30 cc.  $\text{H}_2\text{O}$  and titrate with a soln. of Fe alum (15 g. in one l.  $\text{H}_2\text{O}$ ), using 20%  $\text{NH}_4\text{CNS}$  as indicator on a spot plate. With this (a) soln. as a standard, weigh 2 g. of the unknown product (dried at  $35^\circ$ ) into a 200-cc. graduated flask containing 120 cc.  $\text{Me}_2\text{CO}$ . Make up to the mark with distd.  $\text{H}_2\text{O}$ , mix, allow impurities to settle, pipet off 100 cc. and titrate with the Fe alum soln. The error is approx. 1%. For more accurate results, add to the sample of (a) an excess of about 10 cc. of the standard Fe alum soln. and about 50 cc.  $\text{H}_2\text{O}$ . Stir, allow the ppt. to settle and filter through a double tared filter. Wash out Fe salts with cold  $\text{H}_2\text{O}$ , dry at  $70^\circ$  to const. wt. as  $(\text{C}_{10}\text{H}_8\text{ONO})_2\text{Fe}$ . The average error with purified (a) is 0.18%. Two different samples of com. product averaged 97.7 and 75.66% (a), resp.

C. H. KIDWELL.

The freezing points of mixtures of phenols, *o*-cresol, *m*-cresol, and *p*-cresol. HARRY MEDFORTH DAWSON AND CHRISTOPHER ARCHIBALD MOUNTFORD. *J. Chem. Soc.* 113, 923-35(1918).—The isomerides mentioned in the title and their homologs possess very close chemical characteristics and also a close degree of approximation in their physical properties. This greatly narrows the opportunity of providing a satisfactory method for detg. the various components. The PhOH and cresols used were purified by distn. and crystn. The former was obtained from com. carbolic crystals while *m*-cresol and *p*-cresol were of synthetic origin. Some *o*-cresol was obtained from purified com. sample and some was of a synthetic origin. To free them of hygroscopic moisture they were distd. at a sufficient rate for 2-3 hrs to distil over 5-10%. The residual liquid was transferred immediately to a well stoppered bottle. Data given represent the results of observations of the lowest temps. at which complete liquefaction occurs. It was frequently necessary to inoculate supercooled mixts. containing *m*- and *p*-cresols to start crystn. "The f.-p. curves for mixts. of PhOH and *o*-cresol appear to consist of 2 branches corresponding to 2 series of mixed crystals. There is no clear evidence of compd. formation. The curve for mixts. of PhOH and *m*-cresol shows clearly the formation of a compd. containing 1 mol. of PhOH in combination with 2 mols. of *m*-cresol. It is likely to be very considerably dissociated in the liquid state. Its m. p. is  $25.9^\circ$  and the eutectic mixts. which are very characteristic of this binary system correspond with 44.8 and 95.2% by wt. of *m*-cresol, the corresponding temp. being  $20.2^\circ$  and  $7.3^\circ$ . The curve system of PhOH and *p*-cresol would seem to indicate the formation of a compd. which crystallizes at low temps. from a limited range of mixts. containing PhOH in excess. Mixts. of *o*- and *m*-cresol seem to form a compd. in which 2 mols. of *o*-cresol and 1 molecule of *m*-cresol are combined. With *o*- and *p*-cresol a compd. is evidently formed containing 1 mol. of *o*-cresol and 2 mols. of *p*-cresol, m. approx.  $8.7^\circ$ . With *p*- and *m*-cresol a compd. is formed containing 2 mols. of *m*-cresol combined with 1 mol. of *p*-cresol. the f. p. of PhOH, produced by the addition of *m*- and *p*-cresol, falls continuously as the proportion of the *p*-isomeride in the mixed cresol increases. When *o*-, *m*- and *p*-cresol in equal proportions are added to PhOH the change in f. p. is slightly greater than that produced by *o*-cresol in the same quantity. The f. p. of *o*-cresol is lowered most by *p*-cresol, slightly less by *m*- and much less by PhOH. The f. p. of *m*-cresol is probably lowered more by *p*- than by *o*-cresol. The f. p. of *p*-cresol is lowered nearly equally by the other three.

ERLE M. BILLINGS.

The estimation of phenol and the three isomeric cresols in mixtures of these substances. HARRY MEDFORTH DAWSON AND CHRISTOPHER ARCHIBALD MOUNTFORD. *J. Chem. Soc.* 113, 935-44(1918).—I. Analysis of mixts. of phenol and *o*-cresol: "Owing to the marked variations in density assigned by different authors to *o*-cresol the f. p.

method would seem to give best results. If the mixt. contains PhOH or *o*-cresol in considerable excess ( $d_{40}^{25} > 1.061$  or  $< 1.050$ ), the compn. may be deduced directly from the f. p. of *X*, the PhOH branch being used for the mixts. of higher density and the *o*-cresol branch for those falling within the lower range. If the density lies between the above limits, *X* should be mixed with a known proportion of standard PhOH (m. 40.5°), so as to raise the density of the resulting mixt. *Y* above 1.061. The f. p. of *Y* is then measured. Assuming that *a* parts of *X* are mixed with 100-*a* pts. of PhOH, and that this mixt., *Y*, contains, according to the f.-p. measurement, *y* % of PhOH, then the % of PhOH in *X* is given by  $x = (y - 100 + a)100/a$ . II. *Analysis of mixts. of m-cresol and p-cresol*: "D. and M. do not find that the nitration method (Raschig) gives a yield of trinitro-*m*-cresol independent of the proportions of *o*-, *m*-, and *p*-cresol in the mixt. Neither do they find that *m*-cresol has a greater Br-absorbing capacity. It is found that the *p*-cresol curve is adapted for use in the estn. of *p*-cresol in mixts. of *m*- and *p*-cresols. The ratio of the mixt. to pure *p*-cresol as 1 is to 2 is most convenient. Knowing the f. p. the % of *p*-cresol may be read from the curve." III. *Analysis of ternary mixts. containing o-cresol, m-cresol and p-cresol*: "The method depends on the fact that equal wts. of *o*-cresol and *m*-cresol depress the f. p. to the same extent, and on the further fact that equal wts. of *m*- and *p*-cresol depress the f. p. of *o*-cresol to nearly the same extent. In the application of the method, the unknown mixt. *X* is mixed with a known quant. of pure *p*-cresol, giving a mixt. *Y*, the f. p. of which is detd. From this the % of *p*-cresol in *Y*, and hence in *X*, can be obtained from the f. p. curve corresponding with the numbers given in the table:

|                         |        |       |       |       |       |       |       |         |
|-------------------------|--------|-------|-------|-------|-------|-------|-------|---------|
| <i>p</i> -Cresol %..... | 100    | 95    | 90    | 85    | 80    | 75    | 70    | 65      |
| Freezing point.....     | 34.15° | 30.7° | 27.2° | 23.6° | 20.0° | 16.3° | 12.3° | 7.8° C. |

Similarly, *X* is mixed with a known proportion of pure *o*-cresol, giving a mixt. *Z*, the f. p. of which is also measured. From this the % of *o*-cresol in *Z*, and hence in *X*, may be derived from the f. ps. recorded:

|                         |        |        |       |       |       |       |       |       |
|-------------------------|--------|--------|-------|-------|-------|-------|-------|-------|
| <i>o</i> -Cresol %..... | 100    | 95     | 90    | 85    | 80    | 75    | 70    | 65    |
| Freezing point.....     | 30.45° | 28.05° | 25.6° | 23.1° | 20.4° | 17.5° | 14.4° | 11.0° |

These temps. correspond with the f. p. curve which lies between the curves representing the changes produced in the f. p. of *o*-cresol on the addition of *m*- and *p*-cresol, resp."

IV. *Analysis of quaternary mixts. containing phenol, o-cresol, m-cresol and p-cresol*: Bromination and nitration processes are of little use with quaternary mixts. "The quaternary mixt. *X* is mixed with about half its wt. of *o*-cresol, following the device recommended by Fox and Barker (C. A. 11, 3199; 12, 2507) in connection with the estn. of PhOH. This mixt., *X'*, is then submitted to slow fractional distn. with a still-head of the Raschig type, and by this means *X'* is sepd. into 2 fractions, 1 of which (*A*) consists of a mixt. of PhOH and *o*-cresol and the other (*B*) of a mixt. of *o*-, *m*- and *p*-cresol. The fractions *A* and *B* are then analyzed by application of the f. p. methods of I and III."

## 8. MINERALOGICAL AND GEOLOGICAL CHEMISTRY.

EDGAR T. WHERRY AND J. H. BOWER.

**Crystallography of some Canadian minerals; albite, titanite, scapolite, and polycrase.** EUGENE PORTEVIN. *Geol. Survey, Canada. Am. Mineral.* 4, 11-3(1919).—Albite crystals occur at Templeton, Quebec, in cavernous masses of augite, phlogopite, and feldspar, the cavities being lined with fluorite, the secondary albite, calcite and palygorskite, as an alteration product of the augite. Their habit and forms are noted. Titanite from two localities is similarly described. A large crystal of scapolite from Templeton, intergrown with mica and partly incrustured with minute crystals of pyroxene, is described and figured. Polycrase from Cameron, Ontario, is also figured.

E. T. W.

**Contribution to the knowledge of contact metamorphic ore deposits.** TAKHO KATO. *J. Geol. Soc. Tokyo* 24, No. 281, 1-33(1917).—Veinlets of Ca silicate minerals are frequently noted cutting and ramifying through irregularly recrystd. and saccharoidal limestone. This and other evidence indicates that the larger part of the material of these minerals was derived from magmatic emanations. The following general order is observed: deposition of Ca silicates containing little or no Fe; formation of "skarn" minerals, rich in Fe; sulfides and oxides or ore minerals developed contemporaneously with andradite and hedenbergite, or at the closing epoch of deposition; finally veins of chalcopyrite and other sulfides. The skarn formation begins with a pneumatolytic or pneumatolytic-hydrogenetic stage, followed by hydrothermal stages after the solidification of the magma.

S. G. GORDON.

**British iron ore resources.** H. LOUIS. *Nature* 102, 244-5(1918).—A review.

W. H. ROSS.

**The black sand deposits of southern Oregon and northern California.** R. R. HORNOR. *Bureau of Mines, Tech. Paper* 196, 42 pp.(1918).—Black sand deposits in Humboldt and Del Norte counties, Cal., and Josephine, Curry and Coos counties, Ore., were investigated to det. whether any of the deposits were large enough, and contained enough Au, Pt and Fe, for exploitation. The black sands form lenticular deposits interstratified with sands and gravels, and are due to local concn. on beaches by streams which have derived the material from disintegrating basic igneous rocks of the ferromagnesian type. The sands consist of quartz, olivine, garnet, zircon, and other silicates, with magnetite, chromite, ilmenite, hematite, with a little apatite, picotite, rutile, corundum, Au and Pt. The results of the investigation showed that the deposits lack uniformity in occurrence and metallic content, rarely containing enough Au and Pt for exploitation at a profit, while magnetite, chromite, and ilmenite are generally too scattered and too poor to constitute an important source of Fe ore.

S. G. GORDON.

**The barite deposits of Missouri.** WILLIAM A. TARR. *Univ. Missouri Studies* 3, 111 pp.(1918).—The barite deposits occur in a district of dolomitic limestone of Cambrian age, with some shale, chert, sandstone and conglomerate. The barite is usually in crested, divergent groups of tabular, curved crystals. The usual mineral association is barite, quartz, pyrite or marcasite, limonite pseudomorphous after pyrite or marcasite, galena, sphalerite, and sometimes chalcopyrite, calcite, malachite, smithsonite and cerussite. The barite occurs as veins, disseminated deposits, cave deposits, and residual deposits. The veins are not very strong, although apparently very extensive and persistent, occurring in all the formations. Disseminated barite occurs throughout the Potosi, and to a certain extent in the Proctor, formations, either filling numerous small cavities in the rock, or replacing it. Disseminated barite is much more

abundant near the larger veins, and is probably genetically connected with them. Barite further fills the openings between large blocks of dolomite and in soln. cavities. Crystals in these cave deposits weigh several lbs. each and occur in clusters weighing 200 to 300 lbs. The barite is deposited on the bottoms of the cavities, and veins dipping 60° or more may occur along the sides of the cave. The order of deposition in the caves is the same as in the veins: quartz, pyrite, galena, sphalerite, barite. The residual deposits form the most important economic type, masses of 1000 lbs. occurring in these surface deposits. The barite occurs as loose fragments scattered through a deep red clay, more or less mingled with drusy quartz and chert, or as large masses in disaggregated dolomite at the bottom of the clay, in the Central district being confined to the clay immediately above the dolomite. The residual deposits are due to the concn. of the barite of the other types of deposits by the soln. of the dolomite in weathering. The origin of the barite in the underlying rocks is discussed in detail. It is regarded as improbable that the barite was concd. from the surrounding sedimentary rocks by meteoric waters. It is further pointed out that the mineral association is similar to veins of igneous origin, that the igneous rocks afford an adequate source of Ba, and that the ability of rising heated solns. to transport Ba is greater than that of descending solns. Analyses of the Elvins, Potosi, Proctor, and Gasconade dolomites are given. The major part of the barite is found at an average depth of 4 to 5 feet, holes 10 or 12 feet being rare, although 20 feet has been attained. The mining methods, preparation, and treatment of the barite are described, and 39 uses listed.

S. G. GORDON.

**Further work on the igneous rocks associated with the Carboniferous limestone of the Bristol District.** SIDNEY H. REYNOLDS. *Quart. J. Geol. Soc.* 72, 23-42(1917).—Olivine-bearing rocks including olivine-basalts and olivine-orthoclase-basalts occur in the Carboniferous limestones of the Bristol District. The field relations and petrography, with analyses, are described.

S. G. GORDON.

**The Lurgecombe Mill lamprophyre and its inclusions.** HERBERT G. SMITH. *Quart. J. Geol. Soc.* 72, 77-83(1917).—A petrographic description with an analysis. Inclusions of magnetite, corundum, staurolite and spinel are described, their origin being believed due to fragments of the country rock picked up by the magma in its intrusion.

S. G. GORDON.

**The picrite-teschenite sill of Lugar (Ayrshire).** GEORGE W. TYRRELL. *Quart. J. Geol. Soc.* 72, 84-131(1917).—The rock types described include teschenite, theralite, lugarite, picrite, and peridotite, which form a composite sill. Their field relations, contact phenomena, mineralogic and chem. compn., with a number of analyses, mode of intrusion and differentiation, are described in detail.

S. G. GORDON.

**The pseudotachylite of Parijs (Orange free state) and its relation to "trap-shotten gneiss" and "flinty crush-rock."** S. JAMES SHAND. *Quart. J. Geol. Soc.* 72, 198-221(1917).—The rock occurs as dense black glass veins in granite. The occurrence, petrography, origin and compn. are discussed, and 3 analyses given.

S. G. GORDON.

**The Tertiary volcanic rocks of the district of Mozambique.** ARTHUR HOLMES. *Quart. J. Geol. Soc.* 72, 222-79(1917).—A detailed petrographic description of the volcanic rocks of the district, which include solvsbergite, aegirine-trachyte, trachytoid-phonolite, tephritic pumice, basalt, picrite-basalt, hornblende andesite and pyroxene andesite; includes analyses and a discussion of distribution, period and order of eruption, relationships and origin, and radioactivity.

S. G. GORDON.

**Geology of the coast region of Cheh-Kiang-Sheng.** SEIJIRO NODA. *J. Geol. Soc. Tokyo* 23, No. 268, 14-6(1916).—The topography and geology are briefly noted, and an analysis is given of a K-Na granite.

S. G. GORDON.

**The volcanoes of Japan.** BUNDJIRO KOTO. *J. Geol. Soc. Tokyo* 23, No. 268, 1-13; No. 269, 17-28; No. 270, 29-55; No. 272, 77-94; No. 273, 95-127(1916).—There occur in Japan 170 post-Tertiary and 55 active volcanoes. Their geologic history, distribution, and rock types are reviewed, with analyses of pitchstone from Horai-san and Fukugawa; dacitic (?) obsidian, Hime-shima; rhyodacite and mica-andesite, Sanuki; hornblende andesite, Tsuru-shima and Hime-shima; bronzite andesite, Takahama; and orthobasalt, loc. uncertain. S. G. GORDON.

**The characteristics of the eruption of Sakura-Jima in 1914.** BUNDJIRO KOTO. *J. Geol. Soc. Tokyo* 23, No. 278, 181-204; No. 279, 205-26(1916); 24, No. 280, 1-17 (1917).—The phenomena are discussed under the following headings: predisposing causes, premonitory symptoms, phases of eruptions, mass and dimensions of the lava, temp. of lava, the lapilla, ash and sand (with 2 analyses of ash), the subsidence of the Sakura-jima environs, the ventholes, the spatter eruptions and the formation of domes, and the sublimation products: S, gypsum, sal ammoniac, molysite or erythrosiderite, kremersite, kalinite, halite, chloraluminite, and Fe alum. S. G. GORDON.

**Geological observations in Fiji.** WILBUR GARLAND FOYE. *Proc. Am. Acad. Arts Sci.* 54, 1-145(1918).—This paper comprizes a description of the geology and petrography of the Fiji Islands, with special reference to coral reefs. Analyses are given of soapstone, Fiji and Suva; limestone, Lambasa; tonalite, Vunatoto; olivine basalt, Lautoka; basalt, Nathula; gabbro, Lambasa; andesitic basalt, Tota; olivine basalt, Yanu Yanu; andesitic basalt, Thikombia-i-lau; olivine basalt, Ono Levu; olivine basalt, Kambara; and hornblende andesite, Kandavu. S. G. GORDON.

**The sequence of lavas at the north head, Otago Harbor, Dunedin (New Zealand).** PATRICK MARSHALL. *Quart. J. Geol. Soc.* 70, 382-408(1915).—The succession, petrography, compn., and origin of the different rock types are described. Analyses are given of each of the 25 flows, which include trachyte, phonolite, kaivekite, basalt, and trachydolerite, all of which flowed down the same slope, probably having issued from the same volcanic orifice. S. G. GORDON.

**The constitution of the earth's interior.** R. D. OLDHAM. *Nature* 102, 235-6 (1918).—A synopsis of a discussion at a meeting of the British Geophysical Committee. W. H. ROSS.

## 9. METALLURGY AND METALLOGRAPHY.

WILLIAM BRADY, WILLIAM T. HALL.

**Slime treatment on Cornish frames, with particular reference to the effect of surface.** S. J. TRUSCOTT. *Bull. Inst. Mining Met.* 171, 1-4(1918).—Discussion by W. H. Trewartha-James of a paper by T. (cf. C. A. 12, 465, 1036). The author has plotted a curve showing the loss of "Sn" in the process of enrichment. The curve is entirely opposed to Truscott's theory that the last portion of the gang is the most difficult to remove. The following conclusions are drawn from the tests by Truscott: (1) That surface *per se* has no inherent effect in concn. work. (2) That the efficiency of concn. operations depends almost entirely on the inclination of the frame in relation to the pulp consistency (or dila.), for a pulp of a given classification.

F. W. SMITHER.

**The development of galena flotation at the Central mine, Broken Hill.** R. J. HARVEY. *Bull. Inst. Mining Met.* 171, 3-13(1918).—Discussion by H. K. Picard *et al.* of a paper by H. (cf. C. A. 13, 302.) F. W. SMITHER.

**Concentration of lead-zinc-silver ore at the Zinc Corporation's mine.** G. C. KLUG. *Mining Sci. Press* 118, 89-92(1919).—A description with flow sheet of the prac-

tice of an Australian plant. The treatment aims at sepg. the ore into the following products: (1) Pb concentrate assaying 66% Pb, by jigging and tabling. (2) The elimination of as much of the calcitic gang as possible in the form of a sand, which assays 5% Zn, 1.6% Pb, and 0.6 oz. Ag, and which is used for filling underground. (3) Collection of all the slime for preferential flotation treatment (Lyster and Seale-Shellshear methods) in the slime unit. (4) The balance forms a Zn middling, which is treated at the Zn concentrator.

F. W. SMITHER.

**The production of the precious metals during the year 1917.** Annual report of the Director of the U. S. Mint for the year ended June 30, 1918. Pp. 259.

E. J. C.

**Gold, silver, copper and lead in South Dakota and Wyoming in 1917.** CHARLES W. HENDERSON. U. S. Geol. Survey, *Mineral Resources of U. S., 1917*, Part I, 153-65 (preprint No. 11, published Jan. 27, 1919); cf. C. A. 12, 128.

E. H.

**Refining gold bullion with chlorine gas and air.** R. R. KAHAN. *Bull. Inst. Mining Met.* 171, 15-6(1918).—Discussion by T. K. Rose of a paper by K. Cf. C. A. 13, 303.

F. W. SMITHER.

**The application of charcoal to the precipitation of gold from its solution in cyanide.** H. R. EDMANDS. *Bull. Inst. Mining Met.* 171, 5-15(1918); cf. C. A. 12, 1453, 1539.—Discussion by A. W. Allen, who claims that the exptl. work of E. and others proves that the pptn. of Au or a Au compd. by charcoal is an adsorption phenomenon and is not due to occluded CO in the pores of the charcoal.

F. W. SMITHER.

**Tinplate manufacture and detinning.** ANON. *Engineering* 106, 701-2(1918).—A review based on a paper by Bailey (cf. C. A. 12, 1453). The detinning processes are discussed, with a description of the Goldschmidt process.

F. W. SMITHER.

**Widening demand for blast furnace slag.** C. A. WRIGHT. *Iron Age* 103, 241-3 (1919).—An illustrated review and discussion of American activities. Among the uses developed are: a concrete aggregate for reinforced concrete buildings, foundations for buildings and heavy machinery; floors, roofs, retaining walls, bridges, culverts; paving, sidewalks, curbs, and gutters; dams, reservoirs; cement blocks, bricks, lintels and fence posts; cushions under brick and block pavements, top dressing and surfacing rough roads; filter material for chem. processes and sewage disposal plants; filler for commercial fertilizer; railroad roadbeds. It is estd. that approx. 20,000,000 tons of slag were produced last year by the blast furnaces in the U. S.

F. W. SMITHER.

**The inflammability of aluminium dust.** A. LEIGHTON. *Bur. Mines, Tech. Paper* 152, 15 pp.(1918).—The author reviews the literature, discusses the properties affecting explosibility, and describes the exptl. procedure followed (Clement-Frazer app.). *Conclusions:* "Although the expts. do not show the exact conditions under which an ignition of the Al dust is obtained, they do show that it may ignite at temps. even lower than those necessary for the ignition of 200-mesh standard Pittsburgh coal dust; also more heat is needed to ignite Al dust. The dust used was a commercial "Al bonze." *Precautions:* Use a ventilating system that will not raise loose dust into suspension nor keep it in circulation. Use a system supplying dry air at a fairly even temp. and see that the vol. of air supplied is enough to remove quickly any H from the room. Have machinery well grounded, well cared for, and properly oiled. Use tools of soft metal as far as practicable. Have machinery inclosed as far as possible. Use vacuum dust-collecting devices over machinery likely to spread dust. Use no naked lights. Isolate dangerous processes in sep. buildings. Avoid wood construction as far as possible. Avoid use of liquids in putting out fires, except, perhaps, oil, with subsequent use of CCl<sub>4</sub>. Use sand or preferably shale dust for fire extinction (the use of Na<sub>2</sub>CO<sub>3</sub> for this purpose should be investigated)."

F. W. SMITHER.

**Report of Committee A-1 on steel.** ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. 1, 100-41(1918).—Slight changes were adopted in the specifications for forgings, car axles, welded steel and wrought-Fe pipe, boiler and firebox steel and for structural steel used in car manuf. E. E. R.

**Report of Committee A-2 on wrought iron.** ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 142-5(1918).—Changes are proposed in the specifications for boiler tubes, staybolt iron, engine-bolt iron, refined bars, iron plate and iron and steel chain. E. E. R.

**Report of Committee A-3 on cast iron.** ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 156-7(1918).—A hardness test is introduced and the behavior of cast iron when acted upon by superheated steam has been studied. E. E. R.

**Report of Committee A-5 on corrosion of iron and steel.** ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 158-242(1918).—Extensive corrosion tests were started at Pittsburgh, Pa., and at Annapolis, Md., in Dec., 1916, and at Fort Sheridan, Ill., in 1917. The various exposed sheets of metal have been inspected in April and October of each year. The exposure of the sheets at Fort Sheridan and at Annapolis has been too short to develop failure in any of the sheets but at Pittsburgh some failures are reported. The chem. compn. of each of the 715 sheets is given. The detailed reports of the inspectors are tabulated and photographs shown of all sheets that had failed up to April, 1918. In Appendix III of this report the chairman of the committee, HENRY S. RAWDON, describes the *microstructure of 4 types of Zn coatings on Fe and steel* and compares them with the coating obtained when Fe is held for a relatively long period in contact with molten Zn such that conditions approaching equil. are obtained. Hot-dipped and sherardized coatings are shown to be fairly complex in structure and considerable alloying with the Fe takes place. The sprayed and electrolytically deposited coatings have a more simple structure. The alloy layers stand in the same general relation to Fe in their electrolytic solution tension as does Zn itself though not to the same degree; hence they do not accelerate the corrosion of the Fe base though they may cause the outer Zn to disappear at a more rapid rate than if they were not present. The mechanical properties of the hot-dipped coatings are influenced considerably by the degree to which the alloy layers are developed. This appears to depend more upon the time of keeping the sheets in the bath than upon the mere thickness of the coating. The uniformity of thickness in the coatings obtained by spraying or electrolytically together with the av. thickness appear to be the principal factors detg. the efficiency of such coatings. Great variations in thickness of electrolytic deposits were found even on flat surfaces. In Appendix IV, the method of making the salt-spray corrosion test is described. E. E. R.

**Report of Committee A-6 on magnetic properties.** ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 243-5(1918). E. E. R.

**Report of Committee B-2 on non-ferrous metals and alloys.** ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 246-9(1918). E. E. R.

**Report of Committee E-1 on methods of testing.** ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 399-421.—Appendix II of this report contains a valuable discussion of tension tests of steel with specimens of various size and form. E. E. R.

**Report of Committee E-4 on magnification scales for micrographs.** ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 425-7(1919). E. E. R.

**Grain size of iron as affected by temperature.** D. J. McADAM, JR. *Proc. Am. Soc. Testing Materials* 18, Pt. II, 68-86(1918).—The effect of temp. on the grain size of ingot Fe was detd., with other factors, such as strain gradient and temp. gradient, eliminated as much as possible. Curves and tables are given showing the effect of

temp. and time of annealing on the size of the grains. As in a previous paper (*Ibid* 17, Pt. II, 58(1917)), M. concludes that below 785° the coalescence tendency of recrystd. grains is slight. Above 785°, the coalescence tendency grows with increasing rapidity; it reaches a max. at about 870°.

S. G. SIMPSON.

**Changes within the critical range of a given steel: from  $Ac_1$  to  $Ac_{3-2}$ .** J. G. AYERS, JR. *Proc. Am. Soc. Testing Materials* 18, Pt. II, 87-97(1918).—One end of a strip of 0.50% C steel was heated well above its crit. range, the entire specimen was quenched in  $H_2O$ , the surface carefully ground off, and photomicrographs were taken all along the specimen. Reproductions of these at representative points are given and the structure shown in each case is briefly described.

S. G. SIMPSON.

**Season cracking and splitting of condenser tubes and pipes.** WILLIAM CAMPBELL. *Proc. Am. Soc. Testing Materials* 18, Pt. II, 147-52(1918).—Several samples of split brass condenser tubes were examd. Twelve samples from the sound portions of the tubes were immersed in  $HgNO_3$  soln. Only one sample showed internal strain by splitting open. It is concluded that either the longitudinal cracks in the remaining condenser tubes were not due to internal strains revealed by the test or else the strains were localized and were relieved by the splitting. The article is accompanied by several photomicrographs showing the various types of structures examd.

S. G. SIMPSON.

**The causes and prevention of corrosion cracking.** W. H. BASSETT. *Proc. Am. Soc. Testing Materials* 18, Pt. II, 153-62(1918).—Season cracking and fire cracking occur in Cu-Zn alloys only when they contain less than 80% Cu. Cu-Zn-Ni alloys are subject to cracking, but pure Cu-Ni alloys are not. Cu-Sn and Cu-Al alloys when made hard by cold deformation are sensitive to cracking only when low in Cu. With wrought brasses in the  $\alpha$ -phase, the cracks pass between the crystals; in the  $\beta$ -phase the cracks pass across the crystals, and in both  $\alpha$ - and  $\beta$ -phases, the cracks pass through the  $\beta$ . Both internal strain and corrosion are always factors in the cracking of brasses, and atmospheric conditions greatly influence the rate of failing. The presence of Pb, Sn, Fe, etc., apparently has little effect except by increasing resistance to corrosion, although expts. with brasses containing varying amts. of Cd showed that Cd increases the ductility of brass and thereby decreases its liability to crack on account of internal strains. Cracking is prevented by frequent polishing, by annealing, and by regulating the deformation so as to diminish strains.

S. G. SIMPSON.

**Season cracking.** W. RUBEN WEBSTER. *Proc. Am. Soc. Testing Materials* 18, Pt. II, 163-4(1918).—A brief discussion of the phenomenon of season cracking of brass. W. claims the common test for internal strain with  $HgNO_3$  to be too severe and not one to be given general application.

S. G. SIMPSON.

**Initial stress and corrosion cracking.** P. D. MERICA AND R. W. WOODWARD. *Proc. Am. Soc. Testing Materials* 18, Pt. II, 165-78(1918).—Initial stress in a brass is due to the fact that the heating, rolling or working of the brass is not applied uniformly. It may also occur in a material which is not uniform in compn.; thus, when 60-40 brass consisting of the  $\alpha$ - and  $\beta$ -solid soln. is suddenly cooled, the difference in the coeff. of expansion of the 2 phases leaves the  $\alpha$ -particles in tension. Such stresses may amount to 16,000 lbs. per sq. in. Several methods of measuring initial stress are reviewed, and it is concluded that the Hg salt soln. test is a necessary one in the testing and inspection of brasses. 60-40 brasses subject to corrosion cracking only when the surface layers are under an initial stress greater than 25,000 lbs. per sq. in., but M. and W. suggest that a limit of 15,000 lbs. be required. With 60-40 brasses which are to be subjected to tensile stress in service, the sum of the surface layer initial stress and the externally applied stress should not exceed this limit. Initial stress may be sufficiently

eliminated by annealing at 200° or by a mechanical process which introduces a stress at the surface of opposite sign to that already present—the latter method being the more promising for production purposes.

S. G. SIMPSON.

**The prevention of season and corrosion cracking of brass artillery cases by special heat treatment.** W. B. PRICE. *Proc. Am. Soc. Testing Materials* 18, Pt. II, 179-88 (1918).—Sixteen samples of 75 mm. brass cases not heat-treated were subjected to the Government test of immersion for 4 hrs. in a 1.5% soln. of  $\text{HgCl}_2$ . Five of them developed cracks. A number of cases from the same lots was then heated for periods of 1, 2 and 3 hrs. at 500° F. Not one of these failed in the  $\text{HgCl}_2$  test, thereby showing marked diminution in the degree of internal strain. It is also certain that the heat treatment left the cases in a condition to resist corrosion or season cracking on the ballistic test and on long standing; and it is probable that the heat treatment increased the tensile strength several thousand lbs. per sq. in. Photomicrographs show that the heat treatment did not affect the structure except for slight local recrystns. in those cases subjected to the longer heat treatments.

S. G. SIMPSON.

**The use of mercury solutions for predicting season cracking in brass.** HENRY S. RAWDON. *Proc. Am. Soc. Testing Materials* 18, Pt. II, 189-200(1918).—Solns. of the  $\text{Hg}^{\text{I}}$  series of salts are considerably more active than solns. of the  $\text{Hg}^{\text{II}}$  series in promoting the cracking of highly stressed brass of the 60-40 type. In the rods used, the action of the  $\text{Hg}^{\text{I}}$  soln. was, in general, localized in producing one deep crack; the  $\text{Hg}^{\text{II}}$  solns. caused the specimen to crack in several places. The size of the specimen was found to be negligible with material in which the stresses producing the cracks lie in the plane of the cuts made in sampling the piece. In other types of material, the size of the piece must be given consideration. The character of the surface is a factor of considerable importance in detg. the immersion period required to produce cracking. Simple polishing of the surface was sufficient to increase this period in the ratio of 1:6 or 7. Specimens which are required to stand a specified period of immersion should be examd. after they have stood for some time after being removed from the soln. as well as when first removed. The Hg dissolved especially by the  $\beta$  constituent reduces the cohesion between adjacent crystals sufficiently so that intercryst. type of fracture results.

S. G. SIMPSON.

**A simple type of Brinell testing machine for 500 kg. load.** A. V. DE FOREST. *Proc. Am. Soc. Testing Materials* 18, Pt. II, 449-59(1918).—A simple and inexpensive type of Brinell machine for 500 kg. load is described. A series of measurements with 5 diff. machines shows the errors involved in the test on annealed brass, and the simple type of machine is proved to be satisfactory. The hardness of annealed brass in the finished sheet sometimes varies by 2 or 3 Brinell hardness nos. in as many inches. This is shown not to be an error in the machine. It is therefore desirable to make several indentations in each sample. As individual Brinell machines may have considerable systematic error, it is suggested that some standard method of calibration be devised. A method is described by which 2 samples may be tested at once with the machine by placing the Brinell ball in a flexible holder between the 2 specimens. Other suggestions are made as to the possibility of obtaining speed and accuracy with this method of hardness detn.

S. G. SIMPSON.

**A new method of obtaining Brinell hardness.** J. G. AYERS, JR. *Proc. Am. Soc. Testing Materials* 18, Pt. II, 460-77(1918).—Instead of using a dead load hydraulically applied as in the general type of Brinell machine, a definite impact was employed. This impact was obtained by fastening the Brinell ball to the bottom of a given weight and allowing it to drop from a given height upon the test specimen. From the diam. of the impression thus produced, the true Brinell hardness no. may be obtained from a conversion table. The machine is stated to be simple in construction, rapid in action,

and sufficiently accurate for most commercial testing. The discussion following the article brings out the fact that A.'s method is not new, and that it has been found that the harder the metal is, the greater the difference between the hardness nos. detd. by using a gradually applied static load and those detd. by impact. **Iron; furnaces**. P. F. CHARLES, E. F. BRODERICK and E. A. KIRBY. *Brit.* 120,400, Sep. 6, 1916. For making wrought Fe, pig Fe is initially melted, fluxed and boiled in a rotary furnace without manual labor, up to the point of graining the Fe, and the boiling furnace is then moved bodily and tilted so as to transfer the charge to a

stationary balling or puddling furnace in which the metal is further treated and formed into balls by manual labor. Two rotary boiling furnaces are arranged one on either side of a puddling furnace and are adapted to be swung bodily on cranes over the latter and tilted to discharge their contents into it, one after the other, when the door below a charging hopper is opened. The puddling furnace has a vertically sliding door at each side or end, with a puddling or balling opening therein. The rotary boiling furnaces are constructed with a fixed fire chamber and a fixed chimney flue with a charging door. The rotary body rests on rollers and is operated by a rack and pinion. It may be disengaged from the fixed portions to enable it to be lifted and swung by the cranes.

**Malleableizing cast iron.** F. PERRY and INDUSTRIAL INVENTIONS, LTD. Brit. 121,074, Apr. 26, 1918. Fe castings to be malleableized are heated in the presence of Mond, blast-furnace, or like gas contg.  $\text{CO}_2$  and H. Sufficient CO is preferably present to prevent excessive decompn. of the  $\text{CO}_2$  by the H. S and hydrocarbons are preferably removed from the gas before use. The temp. of treatment is  $700\text{--}800^\circ$  for black-heart castings, and  $800\text{--}950^\circ$  for white-heart castings.

**Open-hearth steel.** H. C. RYDING and A. W. ALLEN. U. S. 1,289,057, Dec. 24. Open-hearth steel from all-blown metal is made according to the following procedure: The furnace is first charged with lime and Fe oxide and then with low-C molten blown metal and the materials are heated until the bath and slag are in proper condition, after which high-C blown metal is added and the charge is poured after the finishing operation. As a second operation, the open-hearth furnace is charged first with low-C molten blown metal and then with lime and  $\text{Fe}_2\text{O}_3$ , followed by heating and addition of high-C molten blown metal before finishing and pouring the charge. The first operation serves to build up the furnace bottom and the second to erode it, the 2 procedures in alternation thus serving to maintain the furnace in substantially uniform condition.

**Casting metals.** E. HAMELIUS. Brit. 120,706, July 6, 1918. In order to give greater cohesion and less porosity to cores made of white sand, about 4% of litharge is added to the linseed oil to form the agglomerating material.

**Alloys.** COOPER CO. Brit. 120,565, Oct. 15, 1918. Alloys consisting of Al and Be, the proportion of Be being from 1 to 99% of the whole. The alloys may be prepd. by melting the metals together or by electrolyzing a soln. of the mixed oxides.

**Alloys; torpedoes.** STABILIMENTI BIAK-ING. A. POUCHAIN. Brit. 120,557, Oct. 8, 1918. Making parts of torpedoes, especially guns in the nose thereof, for destroying defense nets, of high resistance alloys of Al with Fe, Ni, Zn, Cu and Mn, *e. g.*, an alloy containing 2% Mn, 1% Fe, and the rest Al; or 5% Cu and the rest Al; or 10% Zn and the rest Al.

## 10. ORGANIC CHEMISTRY.

CHAS. A. ROUILLER.

**Bromination of some derivatives of veratrole.** JOHN L. SIMONSEN AND MADYAR GOPALA RAU. Presidency Coll., Madras. *J. Chem. Soc.* 113, 782-90(1918).—The bromination of 2,3-MeO(AcHN) $\text{C}_6\text{H}_3\text{OMe}$ (A) in  $\text{CHCl}_3$  with a cold  $\text{Br-CHCl}_3$  soln., followed by treatment with  $\text{H}_2\text{O}$ , gave rise to 6-bromo-3-acetylaminoveratrole (B), 2,3,6-MeO(AcHN) $\text{BrC}_6\text{H}_3\text{OMe}$ , prismatic needles from aq. AcOH, m.  $78^\circ$ . When treated with HCl at about  $100^\circ$ , (B) was converted into 6-bromo-3-aminoveratrole (C), needles from dil. MeOH, m.  $66^\circ$ . The benzoyl derivative (C), needles from dil. EtOH, m.  $75^\circ$ . 3-Bromoveratrole (D), 2,3-(MeO) $\text{BrC}_6\text{H}_3\text{OMe}$ , b.  $114^\circ$ , was formed by the diazotization of 2,3-MeO( $\text{H}_2\text{N}$ ) $\text{C}_6\text{H}_3\text{OMe}$ , followed by treatment with  $\text{Cu}_2\text{Br}_2$ . (D) was converted

into 2,4,6-MeO(O<sub>2</sub>N)BrC<sub>6</sub>H<sub>2</sub>OMe, m. 112–3° (cf. Jones and Robinson, *J. Chem. Soc.* 111, 903(1917)), when treated with HNO<sub>3</sub> (d. 1.4) in AcOH. (D) was also formed when (C) was treated with AmNO<sub>2</sub> in EtOH. When 5 g. (A) in 20 cc. cold 50% AcOH was gradually treated with 4.2 g. Br, the mixt. dild. with H<sub>2</sub>O, and the soln. neutralized with NH<sub>4</sub>OH, a mixt. of 5.5 g. (B) and 2 g. 4- or 5-bromo-3-acetaminoveratrole (E), octahedra from Me<sub>2</sub>CO, m. 151°, was obtained. (E) was sepd. from (B) by means of its lower soly. in Me<sub>2</sub>CO. The corresponding free amine (F), needles from aq. MeOH, m. 49°. The benzoyl derivative of (F), needles, m. 146°; chloroplatinate of (F) forms yellowish brown prisms (from aq. HCl). On diazotization, (E) yields 2,4-(MeO)BrC<sub>6</sub>H<sub>2</sub>OMe, m. 123°. Bromination of 2,4-MeO(AcHN)C<sub>6</sub>H<sub>2</sub>OMe in either CHCl<sub>3</sub> or AcOH yielded only 2,4,5-MeO(AcHN)BrC<sub>6</sub>H<sub>2</sub>OMe, needles, m. 127–8°, which on careful treatment with KOH in MeOH, yielded 5-bromo-4-aminoveratrole (G), needles from MeOH, m. 51°. The benzoyl derivative, needles, m. 142°. The constitution of (G) was shown by diazotization and conversion into (the known) 2,4,5-MeOBrC<sub>6</sub>H<sub>2</sub>OMe, m. 92°. 2,3,4-MeO(AcHN)(HO<sub>2</sub>C)C<sub>6</sub>H<sub>2</sub>OMe in AcOH, when treated with Br in AcOH, yielded 5-bromo-2-acetylaminoveratric acid (H), fine needles, m. 188–9°. When the reaction is carried out in CHCl<sub>3</sub> (H) is formed together with (E). On hydrolysis, (H) gave 5-bromo-2-aminoveratric acid, colorless prisms, m. 158–9°, the constitution of which was shown by its conversion into 5-bromoveratric acid, m. 191°. The bromination of 5-acetaminoveratric acid in AcOH gave rise to 2-bromo-5-acetaminoveratric acid, 2,3,4,5-Br(MeO)<sub>2</sub>(AcHN)C<sub>6</sub>HCO<sub>2</sub>H, needles from aq. alc., m. 221°, which on hydrolysis yielded 2-bromo-5-aminoveratric acid, prisms, m. 183°. The latter, on diazotization, gave 2-bromoveratric acid, m. 201–2°. 6-Acetaminoveratric acid, when brominated in CHCl<sub>3</sub> suspension, yielded 2,4,5-MeO(AcHN)BrC<sub>6</sub>H<sub>2</sub>OMe, m. 127–8°. No other product was isolated.

LOUIS E. WISE.

**Relative activity of certain alkyl iodides with sodium  $\alpha$ -naphthoxide.** HENRY E. COX. *J. Chem. Soc.* 113, 821–4(1918); cf. *C. A.* 13, 312.—The interaction of MeI and Na  $\alpha$ -naphthoxide (A) in MeOH at 40° was studied. The reaction is bimol., and the velocity coeff. increases with diln. in accordance with the equation:  $k_p = k_1 + a \log v$ , as far as  $v = 8$ . Thereafter the increase is more rapid. Variations in the concn. of MeI have little effect on the rate of reaction but changes in the initial concn. of (A) affect the velocity coeff. very appreciably. The coeff. is not affected by NaI, but  $\alpha$ -C<sub>10</sub>H<sub>7</sub>OMe (the other product of the interaction of (A) with MeI) greatly retards the reaction. The velocity of the reaction between MeI, EtI and PrI and (A), is about twice as great (in each case) in EtOH as it is in MeOH. The relative activities of the alkyl iodides are as follows: MeI > EtI > PrI.

LOUIS E. WISE.

**Theory of the electrochemical hydrocarbon synthesis of Hermann Kolbe.** F. FICHTER AND E. KRUMMENACHER. *Helvetica Chimica Acta* 1, 146–66(1918); *Arch. sci. phys. nat.* 44, 383–4(1917).—Two theories have been formulated to explain the formation of hydrocarbons by the electrolysis of salts of fatty acids (Kolbe's synthesis). Crum, Brown and Walker (*Ann.* 261, 107(1891)) seek to explain the mechanism of the reaction on the basis of lost charges from the anion, as follows:  $2R.COO^- + 2^+ \longrightarrow 2RCOO \longrightarrow R-R + 2CO_2$ ; whereas Schall (*Z. Elektrochem.* [3] 83 (1896)) states that acid peroxides are first formed (at the anode) which then decomp. to yield CO<sub>2</sub> and the hydrocarbon:  $RCO_2-CO_2R \longrightarrow R-R + 2CO_2$ . Although C., B. and W.'s theory has gained preëminence, F. and K. are inclined towards S.'s peroxide theory, which is apparently supported by their own exptl. work with acyl peroxides. (AcO)<sub>2</sub>, prepd. by Clover and Richmond's method (*J. Am. Chem. Soc.* 29, 179) explodes readily and is hardly suitable for quant. experimentation. It appears to decomp. (in part at least) into CO<sub>2</sub> and C<sub>2</sub>H<sub>6</sub>, and CH<sub>4</sub> is an appreciable by-product in the reaction. (Et-CO<sub>2</sub>)<sub>2</sub> (A), which is a liquid, far more stable than (AcO)<sub>2</sub>, was formed by Clover's

method (Thesis, Univ. Michigan, 1914). (A) explodes at 80°, but decomps. rather gradually when heated at 60°. Products of decompn. were butane, CO<sub>2</sub>, CH<sub>4</sub> and EtCO<sub>2</sub>Et. The principal reaction is probably represented by the following equation:  $2(A) \longrightarrow C_4H_{10} + 2CO_2$ . The formation of CH<sub>4</sub> may perhaps be explained by the hydrolysis of (A):  $(A) + H_2O \longrightarrow CH_4 + CO_2 + MeCOCO_2H$ . EtCO<sub>2</sub>Et is produced in very small amt. *Perpropionic acid* (B), EtCO<sub>2</sub>H, which was formed by the action of pure H<sub>2</sub>O<sub>2</sub> upon (EtCO)<sub>2</sub>O (cf. Ahrle, *J. prakt. Chem.* [2] 79, 129(1909)) is far less explosive than MeCO<sub>2</sub>H. The decompn. of (B), effected by heating in a steel autoclave, gave rise to CO<sub>2</sub>, mixed with smaller amts. of CH<sub>2</sub>:CH<sub>2</sub>, C<sub>2</sub>H<sub>4</sub> and CH<sub>4</sub>. It appears that the decompn. of (B) at moderate temp. gives rise to EtOH and CO<sub>2</sub>, whereas CH<sub>2</sub>:CH<sub>2</sub>, H<sub>2</sub>O and CO<sub>2</sub> are formed when (B) is heated to a higher temp.

LOUIS E. WISE.

**Nitrones and nitrenes.** H. STAUDINGER AND K. MIESCHER. *Arch. sci. phys. nat.* 44, 387-8(1917).—The nitrones and nitrenes prep'd. by S. and M. bear the same relation to PhNO<sub>2</sub> as Ph<sub>2</sub>C:C:O (ketene) and Ph<sub>2</sub>C:C:CPh<sub>2</sub> (allene) bear to CO<sub>2</sub>. The nitrones also resemble the ketenes in intensity of color and in their chem. activity. Phenyl diazomethane reacting with PhNO yields the *nitrone*, PhCH:NPh:O (A), which is identical with the comp'd. obtained by the interaction of BzH and PhNHOH. (A) unites with either 1 or 2 mols. of Ph<sub>2</sub>C:C:O (B) (diphenylketene). The addition product of (A) with 1 mol. (B) loses CO<sub>2</sub> when heated, yielding the *nitrene* (C) Ph<sub>2</sub>C:NPh:CPh<sub>2</sub>. The nitrenes add 1 but not 2 mols. of (B). The addition product derived from (B) and (C) is represented by the formula:  $\text{PhN} \cdot \text{CPh}_2 \cdot \text{CO} \cdot \text{CPh}_2 \cdot \text{CPh}_2$ . Physical

properties of the above compds. are not given.

LOUIS E. WISE.

**Contribution to the study of holocaine.** L. REUTTER DE ROSEMONT. *Arch. sci. phys. nat.* 44, 389-90(1917).—An unsuccessful attempt to synthesize holocaine (A) is described. The interaction at 40° of 32 g. (EtOC<sub>4</sub>H<sub>9</sub>NH)<sub>2</sub>CS and 12 g. KCN in 40 g. H<sub>2</sub>O, in the presence of 75 g. PbCO<sub>3</sub> and 100 g. EtOH, gave rise to the *nitrite*, EtOC<sub>4</sub>H<sub>9</sub>NHC(CN):NC<sub>4</sub>H<sub>9</sub>OEt (B), yellow prisms from Et<sub>2</sub>O, m. 104°. When 40 g. (B) was heated at 30-45° with 150 g. yellow (NH<sub>4</sub>)<sub>2</sub>S, the compound, EtOC<sub>4</sub>H<sub>9</sub>NHC-[C(NH<sub>2</sub>):S]:NC<sub>4</sub>H<sub>9</sub>OEt, yellow prisms, m. 124°, was obtained. The latter when heated on the water bath with HCl gave rise to the compound (C), C<sub>11</sub>H<sub>27</sub>O<sub>2</sub>N<sub>2</sub>Cl (probably EtOC<sub>4</sub>H<sub>9</sub>NH(HCl)C(CONH<sub>2</sub>):NC<sub>4</sub>H<sub>9</sub>OEt), cream-colored crystals, m. 220°. Reduction of (C) by means of Na or NaHSO<sub>3</sub> did not yield (A).

LOUIS E. WISE.

**Steric hindrance.** S. REICH. *Arch. sci. phys. nat.* 44, 403-4(1917).—The reactivity of *o*-disubstituted aldehydes does not decrease with increasing wt. of the substituent group. 2,6-(O<sub>2</sub>N)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>CHO (A) is in fact more reactive than 2,6-Cl<sub>2</sub>C<sub>6</sub>H<sub>3</sub>CHO (B), which in turn is more active than 2,4,6-Me<sub>3</sub>C<sub>6</sub>H<sub>3</sub>CHO (C). (A), when heated with AcONa and Ac<sub>2</sub>O for 2 hrs. at 140-5°, is quant. converted into 2,6-(O<sub>2</sub>N)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>CH:CHCO<sub>2</sub>H. Under similar conditions (B) gives a 30-40% yield of 2,6-Cl<sub>2</sub>C<sub>6</sub>H<sub>3</sub>CH:CHCO<sub>2</sub>H and an 80% yield of this acid when the reaction is carried out at 180°. R. was unable to convert (C) into 2,4,6-Me<sub>3</sub>C<sub>6</sub>H<sub>3</sub>CH:CHCO<sub>2</sub>H. The presence of 2Cl atoms (in positions 2 and 6) reduces the reactivity of a CO<sub>2</sub>Et group towards PhMgBr, but such an effect is not apparent in the case of (B), which reacts very readily with PhMgBr.

LOUIS E. WISE.

**Study of the acid function in methenic and methinic acids.** J. GUINCHANT. *Ann. chim.* (9) 9, 49-143; 10, 30-84(1918).—(From a thesis submitted at the Univ. of Sorbonne in 1897 and not previously published in any scientific journal.) To det. the constitution of methenic and methinic acids expts. were made with a number of acids of each type. In the group of methinic acids the following new cyanoacetic acids were prep'd., using the method of Haller which consists in heating together the acyl chloride

with the Na salt of the cyanoacetic ester: *methyl propionylcyanoacetate*,  $\text{EtCOCH}(\text{CN})\text{CO}_2\text{Me}$ , long silky needles from  $\text{Et}_2\text{O}$ , m.  $30^\circ$ ,  $b_{25} 136^\circ$ , very slightly sol. in  $\text{H}_2\text{O}$  but sol. in  $\text{Et}_2\text{O}$  and  $\text{CHCl}_3$ ; *sodium salt*, needles, containing 1 mol. of  $\text{H}_2\text{O}$  which lost its  $\text{H}_2\text{O}$  when heated at  $100^\circ$  under reduced pressure; *copper salt*, blue-green spangles, insol. in  $\text{H}_2\text{O}$  but sol. in  $\text{CHCl}_3$  and hot  $\text{EtOH}$ ; *methyl butyrylcyanoacetate*,  $b_{25} 148^\circ$ , which crystd. on cooling and melted at  $0-1^\circ$ ; *sodium salt*, fine needles contg. 2 mols. of  $\text{H}_2\text{O}$  which changed to the anhydrous salt on heating in a vacuum; *copper salt*, dark green crystals from  $\text{EtOH}$ ; *methyl isobutyrylcyanoacetate*, m.  $36-7^\circ$ ,  $b_{25} 139-40^\circ$ , slightly sol. in  $\text{H}_2\text{O}$  but sol. in ligroin or  $\text{PhH}$ ; *sodium salt*, with 1 mol. of  $\text{H}_2\text{O}$  which it lost on drying under reduced pressure; *copper salt*, green plates from  $\text{EtOH}$ ; *propyl acetylcyanoacetate*, fine needles from ligroin, m.  $35-6^\circ$ ,  $b_{25} 133^\circ$ ; *sodium salt*, with 2 mols. of  $\text{H}_2\text{O}$  and becoming anhydrous when dried *in vacuo*; *copper salt*, blue-green plates; *isobutyl acetylcyanoacetate*,  $b_{25} 142^\circ$ ; *sodium salt* containing 4 mols. of  $\text{H}_2\text{O}$  which when kept *in vacuo* at  $20^\circ$  lost 2 of the mols. of  $\text{H}_2\text{O}$  and lost the remaining 2 mols. when kept at  $100^\circ$  *in vacuo*; *copper salt*; *amyl acetylcyanoacetate*,  $b_{25} 168^\circ$ ,  $[\alpha]_D^{25} 2.51^\circ$ ; *sodium salt*, a viscous liquid which crystd. on long standing; *copper salt*, blue-green plates from hot  $\text{PhNO}_2$ . The following other methenic and methinic compds. were similarly prepd. (in some cases they were purchased:  $\text{CH}_3(\text{CN})\text{CO}_2\text{CHMe}_2$ ,  $\text{CH}_3(\text{CN})\text{CO}_2\text{C}_6\text{H}_{11}$ ,  $\text{AcCH}(\text{CO}_2\text{Et})_2$ ,  $(\text{Ac})_2\text{CHCO}_2\text{Et}$ ,  $\text{AcCH}(\text{CN})\text{CO}_2\text{Me}$ ,  $\text{AcCH}(\text{CN})\text{CO}_2\text{Et}$ ,  $\text{Me}(\text{CH}_2)_2\text{COCH}(\text{CN})\text{CO}_2\text{Me}$ ,  $\text{BzCH}(\text{CN})\text{CO}_2\text{Et}$ ,  $(\text{CN})_2\text{CHCO}_2\text{Et}$ ,  $\text{CNCH}(\text{CO}_2\text{Me})_2$ ,  $\text{CNCH}(\text{CO}_2\text{Et})_2$ ,  $\text{CH}_3(\text{CN})\text{CO}_2\text{Me}$ ,  $\text{CH}_3(\text{CN})\text{CO}_2\text{Et}$ ,  $\text{AcCH}_2\text{Ac}$ ,  $\text{AcCH}_2\text{CO}_2\text{Me}$ ,  $\text{AcCH}_2\text{CO}_2\text{Et}$ ,  $\text{CH}_2(\text{CO}_2\text{Me})_2$ ,  $\text{BzCH}(\text{CN})\text{Ac}$ ,  $\text{CH}_3(\text{CN})\text{CONH}_2$ ,  $\text{CH}_3(\text{CONH})_2$ ,  $\text{CH}_3(\text{CN})\text{CO}_2\text{H}$ , and  $\text{BzCN}$ . To det. the constitution of the above compds. five methods were used: the lowering of the f. p. in a  $\text{H}_2\text{O}$  soln. of the Na salts; the cond. of the free acids and the Na salts; the heat of neutralization in the formation of the Na salts; mol. wt. in  $\text{PhH}$  (cryoscopic method); and the heat of combustion. The Na salts of both the methenic and methinic acids gave about the same lowering of the f. p. in  $\text{H}_2\text{O}$  as do the salts of the corresponding fatty acids, and they also show about the same cond. The cond. of the free methenic acids were too small to measure with accuracy, while the free methinic acids gave a much greater ionization const. than the corresponding fatty acids. With  $\text{AcCH}_2\text{Ac}$  the cond. changed with time, due probably to the hydrolysis of the acid to form  $\text{AcOH}$ , and moreover when first placed in soln. the cond. was too small to measure with accuracy. The mol. wt. of the methinic acids when measured cryoscopically in  $\text{PhH}$  gave numbers more analogous to neutral compds. than to the corresponding fatty acids. In their heats of combustion both methenic and methinic acids behaved as though they were ketones,  $\text{AcCH}_2\text{Ac}$  alone being an exception and giving a heat of combustion more like an enolic compd.

R. N. HARGER.

**Synthesis of 1,4,7-trihydroxyheptane, a homolog of ordinary glycerol, and various derivatives of propyltetrahydrofurfuran.** J. HAMONET. *Ann. chim.* 10, 5-30(1918). —When the Mg alkyl compd. of 1,3-methoxypropyl iodide (Grignard reagent) was mixed in  $\text{Et}_2\text{O}$  with  $\text{HCO}_2\text{Et}$  a vigorous reaction took place, producing 1,7-dimethoxy-4-hydroxyheptane,  $(\text{MeOCH}_2\text{CH}_2)_2\text{CHOH}$  (A), together with small quantities of  $\text{MeO}(\text{CH}_2)_4\text{OMe}$  and an aldehyde, probably  $\text{MeO}(\text{CH}_2)_3\text{CHO}$ , the three compds. being sep'd. by fractional distn. (A) is a very bitter liquid, b.  $254-6^\circ$ ,  $b_{25} 141-2^\circ$ ,  $d_{18} 0.969$ ,  $n_D^{18} 1.440$ . When  $\text{PBr}_3$  was allowed to react with (A) the result was 1,7-dimethoxy-4-bromoheptane (B),  $b_{25} 137-9^\circ$ . With  $\text{PCl}_5$  there was formed the corresponding compd., 1,7-dimethoxy-4-chloroheptane, a volatile liquid of very disagreeable odor,  $b_{18} 120-2^\circ$ . H. was unable to isolate the corresponding I compd. either by treating (A) with  $\text{PI}_3$  or (C) with  $\text{KI}$  for in both cases there was formed:  $\text{MeO}(\text{CH}_2)_3\text{CHCH}_2\text{CH}_2\text{CH}_2\text{O}$ .

When  $\text{HI}$  gas was allowed to interact with (A) there resulted 1,4,7-triiodoheptane,<sup>2</sup>

viscid liquid,  $d_{18}$  2.343. The corresponding Br compd., 1,4,7-tribromoheptane (*E*),  $b_{10}$  184-7°,  $d_{18}$  1.775, was obtained by satg. (*A*) with HBr, while if the proportion of HBr was limited and the reaction mixt. cooled in ice the resulting product was 1,7-dibromo-4-hydroxyheptane (*F*),  $d_{18}$  1.620. When an attempt was made to dist. (*F*) it lost half of its Br and formed 3-bromopropyl- $\alpha$ -tetrahydrofurfuran,  $\text{BrCH}_2(\text{CH}_2)_2\text{CH}(\text{CH}_2\text{CH}_2\text{CH}_2\text{O})$  (*G*), a colorless liquid, insol. in  $\text{H}_2\text{O}$ ,  $b_{27}$  115-6°,  $d_{10}$  1.331,  $n_D^{20}$

1.485. Treated with HBr (*G*) yielded (*F*). Compds. (*E*), (*F*) and (*G*), when boiled with  $\text{H}_2\text{O}$ , lost all Br in their mols. and all gave 3-hydroxypropyl- $\alpha$ -tetrahydrofurfuran (*H*), colorless liquid,  $b_{100}$  222-3°,  $b_{18}$  119-20°,  $d_{18}$  1.007,  $n_D^{18}$  1.445, while *H*, when boiled with HBr, was converted into (*E*). The acetate of 3-acetoxypentyl- $\alpha$ -tetrahydrofurfuran,  $b_{14}$  118-20°,  $d_{18}$  1.0201,  $n_D^{18}$  1.448, was formed by treating (*H*) with  $\text{Ac}_2\text{O}$  and  $\text{ZnCl}_2$  as a catalyst, below 125°, while if the temp. was kept at 145-50° the resulting product was 1,4,7-triacetoxypentane,  $[\text{AcOCH}_2(\text{CH}_2)_2]_3\text{CHOAc}$  (*I*),  $b_{17}$  200-2°,  $d_{18}$  1.0872,  $n_D^{18}$  1.447. (*I*) was also obtained by treating (*D*) or the corresponding tri-I compd. with  $\text{AgOAc}$ . On sapong. (*I*) with  $\text{Ba}(\text{OH})_2$ , there resulted 1,4,7-trihydroxyheptane (*J*), a viscid liquid with a sweet taste,  $b_{28}$  230-2°,  $d_6$  1.084,  $d_{18}$  1.075,  $n_D^{18}$  1.4378. It was found that (*J*) could be formed much more easily by treating 1 mol. of (*A*) with 2 mols. of gaseous HI. When (*J*) was boiled with  $\text{H}_2\text{SO}_4$  (1-5 or 1-20) water was split off from (*H*). That the ring closes in these cases in the  $\gamma$ -position was further shown by the fact that when 1,4-dibromobutane was boiled with  $\text{H}_2\text{O}$  the resulting product was tetrahydrofurfuran while the same compd. was formed by boiling 1,4-diiodobutane with  $\text{Ag}_2\text{O}$ .

R. N. HARGER.

The nitro derivatives of phenyl-2-naphthylamine. HUGH RYAN AND JAMES J. DRUMM. Univ. College, Dublin. *Proc. Roy. Irish Acad.* 34B, 165-74.—This investigation was undertaken to det. whether the stabilizing properties of phenylacetyl-2-naphthalide (*A*) for nitrocellulose powders are due to its power of combining with  $\text{HNO}_3$  and  $\text{HNO}_2$  to its action as a negative accelerating agent or to its gelatinizing properties.  $\text{NO}_2$ , the nitrating constituent of dry nitrous fumes, prepd. by heating dry  $\text{Pb}(\text{NO}_2)_2$ , has no action on (*A*) in anhydrous  $\text{Et}_2\text{O}$  but in moist  $\text{Et}_2\text{O}$  phenyl-2-naphthylamine (*B*) (white prisms from  $\text{C}_6\text{H}_6$ , m. 107°) occurs by hydrolysis and upon evapn. of the  $\text{Et}_2\text{O}$  soln. colorless cubical crystals, m. 119-20°, were obtained by recrystn. from boiling xylene. This compd. was a mono- $\text{NO}_2$  deriv. of (*B*). The following results indicate that the 119° product is probably 3-nitrophenyl-2-naphthylamine: 1-Nitrophenyl-2-naphthylamine was prepd. by Goldberg's method (*Ber.* 40, 4541(1907)) in which the reaction between the amine and the halogen compd. proceeds in  $\text{PhNO}_2$  soln. in the presence of Cu dust, KI, and  $\text{K}_2\text{CO}_3$ . It crystd. from hot alc. as deep red prisms, m. 105-6°, insol. in dil. alc. HCl, sol. in  $\text{Et}_2\text{O}$ , glacial AcOH, or  $\text{C}_6\text{H}_6$ ; sparingly sol. in cold and easily in hot alc. Its soln. in cold concd.  $\text{H}_2\text{SO}_4$  had a deep red color. 4'-Nitrophenyl-2-naphthylamine was prepd. from  $p\text{-BrC}_6\text{H}_4\text{NO}_2$  with 2- $\text{C}_{10}\text{H}_7\text{NH}_2$  (Goldberg). During the removal of  $\text{PhNO}_2$  by steam distn. in these expts. alkali carbonate was neutralized since it attacks many of these  $\text{NO}_2$  compds. Extn. of the soln. with hot  $\text{C}_6\text{H}_6$  after steam distn. yielded yellow crystals, m. 283-4°, readily sol. in  $\text{C}_6\text{H}_6$ , sparingly sol. in cold alc. or  $\text{Et}_2\text{O}$ , and giving a violet-blue color with concd.  $\text{H}_2\text{SO}_4$ . When (*A*) was treated with  $\text{NO}_2$  in abs. alc. a crusty solid sepd. which recrystd. from glacial AcOH in yellow prisms, m. 242-3°, later found to be 2',4',1-trinitrophenyl-2-naphthylamine. From the parent liquid another tri- $\text{NO}_2$  deriv. of (*B*) was obtained by pptn. with  $\text{H}_2\text{O}$  and recrystn. from AcOH; orange prisms, m. 179-80°. Neither of the above compds. is formed when an alc. soln. of the stabilizer (*A*) is treated with colorless concd.  $\text{HNO}_3$  (1-10 mols.) at room temp. 10 days. When (*A*) was triturated with  $\text{HNO}_3$  (d. 1.43) a red sirup formed, which on pouring into  $\text{H}_2\text{O}$  yielded a ppt. This

product, filtered and washed with  $H_2O$ , recrystd. from xylene in yellow cubes, m.  $119-20^\circ$ , identical with that formed by  $NO_2$  in moist  $Et_2O$ . In  $AcOH$  (A) is not acted on by  $HNO_3$  but upon adding  $AmNO_2$ , the yellow tri- $NO_2$  compd., m.  $242^\circ$ , and the orange one, m.  $179^\circ$ , were formed.  $HNO_3$  was slowly added to (B) in  $Et_2O$ . Upon evapn. of the  $Et_2O$  and recrystn. from glacial  $AcOH$ , trinitrophenyl-2-naphthylamine sepd., prisms, m.  $210^\circ$  (decompn.). Addition of  $HNO_3$  to (B) directly, yielded impure resinous products.  $HNO_3$  reacted with (B) in glacial  $AcOH$ , forming crystals, part of which dissolved in boiling glacial  $AcOH$  to form dinitrophenyl-2-naphthylamine, m.  $192-5^\circ$  (Streiff, *Ann.* 209, 157(1881)). The less sol. portion was the orange tri- $NO_2$  compd., m.  $179-80^\circ$ . For exptl. purposes, phenyl-2-naphthylnitrosoamine (C) was prepd. by heating a mixt. of abs. alc. and iso- $AmNO_2$  under a reflux. The pale gray prisms which sepd. on standing were colorless after treatment with animal charcoal; m.  $98^\circ$ , decomp. when boiled with glacial  $AcOH$  or when treated with dil. acids. In abs. alc. (C) is reacted upon by concd.  $HNO_3$  to form a reddish amorphous solid. This product, filtered and crystd. from glacial  $AcOH$  as brown prisms, m.  $170-80^\circ$  (decompn.), was a di- $NO_2$  deriv. of (B). In  $AcOH$  soln., (C) is transformed by  $HNO_3$  (1-6 mol.) into the yellow tri- $NO_2$  compd. of (B), m.  $242-3^\circ$ . The  $242^\circ$  compd. was 2',4',1-trinitrophenyl-2-naphthylamine, prepd. from 2,4-( $O_2N$ ) $_2$  $C_6H_3Cl$  with 1,2- $C_{10}H_7$ ( $NO_2$ ) $_2NH_2$  by Goldberg's method. 2',4'-Dinitrophenyl-2-naphthylamine was made from 2- $C_{10}H_7NH_2$  and 2,4-( $O_2N$ ) $_2$  $C_6H_3Cl$ , crystd. from glacial  $AcOH$  in red prisms, m.  $170-1^\circ$  (Ernst, *Ber.* 23, 3429(1890), and Heim, *Ber.* 21, 589(1888), who used *m*- $C_6H_4$ ( $NO_2$ ) $_2$ ). 2',4',6'-Trinitrophenyl-2-naphthylamine was obtained by heating  $\beta$ - $C_{10}H_7NH_2$  with picryl chloride or Me picrylnitrosoamine (Bamberger and Mueller, *Ber.* 33, 107(1900)), brick-red prisms from glacial  $AcOH$ , orange-yellow from dil.  $AcOH$ , either variety m.  $230^\circ$  (uncorr.). Picryl chloride did not react with 1,2- $C_{10}H_7$ ( $NO_2$ ) $_2NH_2$  even in boiling  $PhNO_2$ . [To obtain the 1,2- $C_{10}H_7$ ( $NO_2$ ) $_2NH_2$ , the corresponding acetanaphthalide (Kleeman, *Ber.* 19, 338(1886)) was first prepd. by nitration of aceto-2-naphthalide; yellow prisms from abs. alc., m.  $123-4^\circ$ . This compd. was hydrolyzed with alc.  $HCl$  to produce the amine, dark brown prisms from alc., m.  $123-4^\circ$ .] 1-Nitro-, 4'-nitro-, and 2',4',1-trinitro-2-naphthylaniline were successfully prepd. by Goldberg's method, but *o*- $NO_2C_6H_4Br$  would not react with 2- $C_{10}H_7NH_2$ , nor *o*- $NO_2C_6H_4NH_2$  with 2- $C_{10}H_7Cl$  under these conditions. From these results it is seen that (A) in alc. soln. treated with  $NO_2$  is first decompd. into the corresponding amine, which is partly nitrated directly to the orange tri- $NO_2$  deriv., m.  $179^\circ$ ; another part (75%) of the amine is converted into (C), which in turn is transformed by  $HNO_3$  into the yellow tri- $NO_2$  compd., m.  $242^\circ$ . For the formation of the latter  $HNO_3$  seems essential.

C. H. KIDWELL.

**Tartaric amides and imides.** II. LUIGI CASALE. Univ. Naples. *Gazz. chim. ital.* 48, I, 114-20(1918); cf. C. A. 12, 1174.—The easy alterability of  $p$ - $H_2NC_6H_4OH$  in the air and in heat makes the prepn. of its amido and imido derivs. with tartaric acid very difficult. Good results were obtained by heating the tartrate and  $p$ - $H_2NC_6H_4OH$  *in vacuo* with a strong dehydrating agent for a few hrs. at  $200^\circ$ . Only the imido deriv. was obtained. Not a trace of the amido deriv. was obtained as with  $PhNH_2$ . It is thought that this may be due to the fact that at this temp. the amido deriv. is unstable and loses  $H_2O$  to give the imido deriv.; no racemization was observed such as might be expected in such a case. A hot  $EtOH$  soln. of *d*-tartaric acid mixed with a hot  $EtOH$  soln. of  $p$ - $H_2NC_6H_4OH$  seps. *p*-aminophenol tartrate (a),  $HO_2C$ -( $CHOH$ ) $_2$ - $CO_2NH_2C_6H_4OH$ , slightly colored scales, m.  $232^\circ$ . (a) heated in a dry vacuum (special app. described) for a sufficient time at  $200^\circ$  melts, loses  $H_2O$ , and gives *p*-hydroxyphenyltartramide (b),  $(CH(OH)CO)_2NC_6H_4OH$ , colorless silky needles from boiling  $H_2O$ , m.  $299^\circ$  (decompn.); 0.3622 g. in 100 cc.  $MeOH$  gives  $[\alpha]_D^{20} +119.64^\circ$ ,

[M] + 267.0°. Unlike phenyltartramide (b) is not saponif. by boiling  $H_2O$ . (b) dissolved in concd.  $NH_4OH$ , in which it is very sol., and heated to 100°, acidified with dil.  $H_2SO_4$ , and cooled seps. *p*-monohydroxyphenyltartramide (c),  $H_2NCO.(CHOH)_2.CONHC_6H_4OH$ , prismatic needles, m. 227°; 0.8408 g. in 100 cc. MeOH gives  $[\alpha]_D^{18} +154^\circ$  and [M] +370°. It may also be prepd. by dissolving (b) in MeOH and passing dry  $NH_3$  into the soln.: (c) seps. on cooling. (c) heated at 150° with  $PhNH_2$  gives *p*-monohydroxydiphenyltartramide,  $PhNHCO.(CHOH)_2.CONHC_6H_4OH$ , silky needles, m. 253°. (c) heated for a short time with the calcd. amt. of 2 N KOH and acidified with concd. HCl gives *p*-hydroxyphenyltartramic acid (d), slightly colored hexagonal plates from  $H_2O$ , m. 218°; 0.550 g. in 100 cc.  $H_2O$  gives  $[\alpha]_D^{14} +108.3^\circ$  and [M] +261.0°; on heating it is slowly converted into the imide without melting. The esters of (d) were obtained by dissolving it in the alc. in question and passing dry HCl into the soln. The ester was obtained by evapg. the alc. Methyl *p*-hydroxyphenyltartrate was obtained as colorless needles, m. 206° with the loss of MeOH and formation of (b) which m. 296°; 0.3884 g. in 100 cc. MeOH gives  $[\alpha]_D^{15} +109.5^\circ$  and [M] +279°. The ethyl ester of (d) was obtained as white opaque plates, m. 118°; 0.3472 g. in 100 cc. MeOH gives  $[\alpha]_D^{15} +106.1^\circ$  and [M] +285.5°. The propyl ester of (d) appears as colorless rhombic tablets, m. 133°; 0.4016 g. in 100 cc. MeOH soln. gives  $[\alpha]_D^{15} +103.8^\circ$ , [M] +294°.

III. *Ibid* 47, II, 63-8(1917).—The importance of the nature of the acid radical substituted on the  $NH_2$  group of *p*-phenetidine in modifying the physiological properties of the derivs. is well known. The acetyl, propionyl, lactyl, dipropylacetyl, dipropylmalonyl, mandelyl and salicyl derivs. have been studied but have the disadvantage of low soly. in  $H_2O$  among others. Piutti prepared Na ethoxyphenylsuccinamate (sol. pyrrantene) and ethoxyphenylsuccinimide which are antithermic and free from secondary actions on the blood. These compds. are inaccessible on account of the high price of succinic acid and so C. has studied the tartaric acid derivs. chemically in detail. *p*-Phenetidine tartrate (a) was placed in a flat dish and kept in an oven at 150-5° for several hrs. The powder was boiled with  $H_2O$  (1 l. for 30 g.) and filtered hot. On cooling *p*-ethoxyphenyltartramide (b),  $(CH(OH)CO)_2NC_6H_4OEt$ , white microcrystals, m. 260°, is sepd.; is not saponif. on boiling with  $H_2O$ ; 0.581 g. in 100 g. MeOH gave  $[\alpha]_D^{14} 115.7^\circ$ , [M] 284°. The insol. residue obtained in the prepn. of (b) is diethoxyphenyltartramide (c),  $[CH(OH)CONHC_6H_4OEt]_2$ , rhombic plates, m. 282°. (c) becomes the main product when the dehydration of (a) is carried out at the m. p. of (a). (c) is also obtained by heating (b) with an equal amt. of *p*-phenetidine at 150-60° for a few min. and crystg. from AcOH. (c) is quickly purified by boiling with  $Me_2CO$  or MeOH; it is nearly insol. in common organic solvents. (b) in hot concd.  $NH_4OH$  is converted into monoethoxyphenyltartramide,  $H_2NCOCH(OH)CH(OH)CONHC_6H_4OEt$ , colorless tablets, m. 237° (decompn.), which seps. on cooling. It is also obtained on passing  $NH_3$  into the hot MeOH soln. of (b). (b) heated a short time at 100° with the calcd. amt. of 2.0 N KOH and acidified with concd. HCl gives ethoxyphenyltartramic acid,  $HO_2CCH(OH)CH(OH)CONHC_6H_4OEt$ , leaves from AcOH, m. 201°, giving the imide; 0.2451 g. in 100 g.  $H_2O$  gave  $[\alpha]_D^{14} 107.1^\circ$ , [M] 288.2°. 2 g. (b) were treated with 10 g. MeOH satd. with HCl gas on a  $H_2O$  bath. On cooling fine prisms of methyl ethoxyphenyltartrate,  $MeO_2CCH(OH)CH(OH)CONHC_6H_4OEt$ , sepd., m. 191°; 0.3952 g. in 100 g. MeOH gave  $[\alpha]_D^{15} 101.2^\circ$ , [M] 286.5°. Ethyl ethoxyphenyltartrate, colorless prisms, m. 175°; 0.16120 in 100 g. MeOH gave  $[\alpha]_D^{14} 98.72^\circ$ , [M] 293.5°.

E. J. WITZEMANN.

The influence of some hydroxy acids on the electric conductivity of boric acid. J. BÖRSEKIN AND H. KALSHOVEN. Delft. *Rec. trav. chim.* 37, 130-43(1918).—The expts. were made with glycolic,  $\beta$ -phenyl- $\alpha$ -hydroxypropionic,  $\beta$ -phenyl- $\beta$ -hydroxy-

propionic and diglycolic acids. The diglycolic acid (a) was prepd. according to Ehlert (*Thesis*, Königsbergen, 1901). 875 g.  $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$  were dissolved in 1 l. hot water. To the cool soln. 250 g.  $\text{ClCH}_2\text{CO}_2\text{H}$  were added and the mixt. was boiled under a reflux for 1 hr. Much Ba diglycolate seps. The dry salt,  $\text{Ba}(\text{O}_2\text{C})_2\text{C}_2\text{H}_4\text{O} \cdot \text{H}_2\text{O}$ , was decompd. with the calcd. amt. of  $\text{H}_2\text{SO}_4$  and evapd. in order to obtain the free acid (a). The substitution of OH in  $\text{CH}_2(\text{OH})\text{CO}_2\text{H}$  with  $\text{OCH}_2\text{CO}_2\text{H}$  causes the product to have a negative action on the cond. of  $\text{H}_2\text{BO}_3$ . Although the two  $\text{CO}_2\text{H}$  groups are in a favorable position for cyclic anhydride formation this does not occur. (a) thus behaves as do succinic and glutaric acids.  $\beta$ -Phenyl- $\beta$ -hydroxypropionic acid (b),  $\text{PhCH}(\text{OH})\text{CH}_2\text{CO}_2\text{H}$ , was prepd. according to Fittig and Binder (*Ann.* 195, 138(1878)). When aq. solns. of (b) are mixed with  $\text{H}_2\text{BO}_3$  the cond. is only slightly less than the sum of the conductivities of the component solns.  $\beta$ -Phenyl- $\alpha$ -hydroxypropionic acid (c),  $\text{PhCH}_2\text{CH}(\text{OH})\text{CO}_2\text{H}$ , was obtained from cinnamic acid by converting it into  $\text{PhCH}_2\text{CHO}$  by the known method (*Ann.* 147, 79(1867); 219, 105(1883); *J. prakt. Chem.* 84, 443) except that  $\text{NaOCl}$  was used. The 50% yield of  $\text{PhCH}_2\text{CHO}$  was quant. converted into  $\text{PhCH}_2\text{CH}(\text{OH})\text{CN}$  and sapond. with  $\text{HCl}$  to give (c). The influence of (c) on the cond. of  $\text{H}_2\text{BO}_3$  is strongly positive and nearly equal to that of lactic acid (*C. A.* 11, 38). Thus the substitution of Ph for H in  $\text{CH}_2$  is without appreciable effect. Verkade and B. (*C. A.* 11, 2895) found that the lowering of the cond. of any acid in 0.5 M  $\text{H}_2\text{BO}_3$  is normal and that the positive influence found with  $\alpha$ -HO acids increases with the cond. of the acid. Earlier data on  $\alpha$ -HO acids from *C. A.* 10, 1856, etc., are given in corrected form and discussed. The curve for pyruvic acid is more sharply inclined, which is interpreted as being due to more complete dissociation on diln. than for the  $\alpha$ -HO acid- $\text{H}_2\text{BO}_3$  complex.

E. J. WITZEMANN.

The influence of some nitrogen derivatives on the conductivity of boric acid. J. BÖRSEKEN, W. STURM AND G. GOETTSCH. Delft. *Rec. trav. chim.* 37, 144-61(1918).—In continuing expts. on the cond. of mixts. of  $\text{H}_2\text{BO}_3$ , compds. containing  $\text{HN} \cdot \text{CO} \cdot \text{NH}$  and  $\text{C}(\text{NH}_2)\text{CO}_2\text{H}$  were used. The ease with which  $\alpha$ - $\text{H}_2\text{NC}_6\text{H}_4\text{OH}$  and  $\alpha$ - $\text{C}_6\text{H}_4\text{C}(\text{NH}_2)_2$  form cyclic compds. with 5 or 6 atoms suggested that they might form highly conductive boro-complexes. Urea, biuret, alloxan, alloxantine, glycine, glutamic, cyanuric and dialuric acids, dihydroxyquinazoline (quinoxaline) and finally uric acid glycol were used. With the exception of glycine and perhaps uric acid glycol these compds. changed the cond. of  $\text{H}_2\text{BO}_3$  solns. only in the normal negative way. The detns. offered some difficulty because of instability of the aq. solns. during the passage of the current. A series of detns. was made and extrapolated to zero time. The urea solns. were quite stable. The biuret was prepd. by heating the urea for some hrs. at 150-70°. After cooling the residue was extd. with cold  $\text{H}_2\text{O}$  and evapd. to dryness. The residue, a mixt. of biuret and urea, was purified by crystn. Cyanuric acid was obtained by heating a mixt. of 10 g.  $\text{CO}(\text{NH}_2)_2$  + 20 g.  $\text{ZnCl}_2$  (anhydrous) at 230°.  $\text{ZnCl}_2$ ,  $\text{CO}(\text{NH}_2)_2$  and biuret were extd. with  $\text{HCl}$ . The increase in cond. for mixts. of  $\text{H}_2\text{BO}_3$  + glycine, with which a boric acid complex is formed, increases with concn., as for the  $\alpha$ -HO acids, but the power to form complexes is less pronounced. The glutamic acid used was prepd. from casein. Dihydroxyquinazoline (quinoxaline) (a) was obtained by the action of  $(\text{CO}_2\text{H})_2$  on  $\alpha$ - $\text{C}_6\text{H}_4(\text{NH}_2)_2$  at 140-60°. Of the two formulas possible for (a) the ketone form should, it seemed, have a slight negative action on the cond. of  $\text{H}_2\text{BO}_3$ , while the enol form should sharply increase the cond. The results favor the ketone formula. Alloxan was chosen because it combines very firmly with a mol. of  $\text{H}_2\text{O}$ . Cond. measurements were difficult with alloxan because of the rapid increase. From the study made with the free compd. it was concluded that its cond., i. e., its acidity, is quite small, in fact  $K = 5 \times 10^{-9}$  is a high figure. In the presence of 0.5 M  $\text{H}_2\text{BO}_3$  the decompn. is retarded but no increase in the acidity of

alloxan was observed. The results conform with the observations of Matignon (*Ann. chim. pharm.* [6] 28, 323(1893)) on the heats of hydration of alloxan. Thus the presence of 2 OH groups bound to a C atom between 2 CO groups is not sufficient for the formation of a  $H_2BO_3$  complex. Dialuric acid (hydroxybarbituric acid) (b) was chosen because of its resemblance to alloxan. Its structural formula may be written in the ketone or enol forms. The latter should have a marked positive influence on the cond. of  $H_2BO_3$ . (b) was prepd. as follows: 16 g. uric acid in 20 cc. HCl (d. 1.19) + 50 cc.  $H_2O$  were boiled under a reflux condenser while 3 g.  $KClO_3$  were gradually added. The alloxan obtained was poured into a hot soln. of 16 g. Sn in 50 cc. HCl (d. 1.19) to which 80 cc. concd. HCl were then added: (b) sepd. as needles after 24 hrs. but contained some alloxantin. To remove this it was heated with 1:1 HCl to which pieces of Sn were added until all alloxantin disappeared. The soln. was heated to boiling in a Jena flask and while cooling a current of  $H_2$  was passed. The cond. was detd. at 25°. In this way the disturbing influence of O in the soln. was eliminated. No increase in cond. was observed when 0.5 M solns. of  $H_2BO_3$  were added. This corresponds to the relation between carbonic and formic acids. (b) should be represented by the ketone formula. Alloxantin was prepd. by Liebig's method. Careful study of its behavior in aq. soln. showed that it is dissociated into dialuric acid and alloxan. The former is rapidly oxidized. This may be demonstrated electrolytically and verified by a microchem. examn. It has no positive action on the cond. of  $H_2BO_3$  and like (b) therefore does not contain two adjoining OH groups in the same plane. Uric acid glycol raises the cond. of  $H_2BO_3$  slightly. The 2 OH groups appear to be situated favorably in order to influence the  $H_2BO_3$ .

E. J. WITZEMANN.

**Preliminary note concerning the influence of boric acid on the electrical conductivity of diacetyl.** J. BÖRSEKEN with G. v. D. HOEK OSTENDE. Delft. *Rec. trav. chim.* 37, 161-4(1918).—B. (C. A. 11, 38) found that the cond. of pyruvic acid (a) undergoes a characteristic increase in 0.5 M  $H_2BO_3$  soln. Trimethylpyruvic acid behaves similarly (C. A. 12, 2548) so that it is probable that (a) hydrates itself thus,  $CH_3C(OH)_2CO_2H$ , and behaves like an  $\alpha$ -HO acid toward  $H_2BO_3$ . It is of interest to know if  $\alpha$ -diketones behave similarly. Diacetyl (b) obtained from com.  $MeCOEt$  through  $MeCOC(:NOH)Me$  was used because it is quite sol. in  $H_2O$ . The preliminary results show a marked positive effect of (b) on the cond. of  $H_2BO_3$  solns. and therefore that (b) is dihydrated in concd. solns. It will be of interest to exam. the influence of diln. on the absorption spectrum. Camphorquinone, a disubstituted  $\alpha$ -diketone, could be obtained only in  $1/100$  M concn. and at this diln. showed no effect on the cond. of (b). The positive effect of (b) diminished rapidly with diln. E. J. WITZEMANN.

**The influence of some  $\alpha$ -hydroxy acids on the electrical conductivity of boric acid.** J. BÖRSEKEN with MISSES J. WEISFELT, J. v. D. SPEK AND CHR. v. LOON AND G. GORTSCH. Delft. *Rec. trav. chim.* 37, 165-78(1918).—The methods were the same as those used in a previous report (preceding abstr.). The  $\alpha$ -hydroxycaprylic acid (a) was prepd. from enanthaldehyde. 58 g. of the latter were agitated with 180 cc. concd.  $NaHSO_3$  soln. until the mass became a thick paste of bisulfite. After filtering and washing with suction with cold  $H_2O$  the bisulfite was ground with 23 g. KCN in 25 g.  $H_2O$ . The oily cyanohydrin was sepd. and heated on the  $H_2O$  bath with 3 parts HCl (d. 1.19). On cooling the acid sepd. and was recrystd. from  $C_6H_6$ . (a) forms needles with a fatty luster. Incidentally the concd. aq. soln. is opalescent and the Na salt forms when agitated. Relatively concd. aq. solns. form 2 liquid layers at 25° when heated gently. Cond. measurements showed that there is a considerable increase in mixts. with  $H_2BO_3$ . Glyceric acid was obtained by oxidizing glycerol with  $HNO_3$  (Debus, *Ann.* 108, 80, 95). Although considerable efforts were made, pure glyceric acid was not obtained when the Pb salt recrystd. 6 times was decompd. with  $H_2S$ . The acid obtained

showed a very positive effect on the cond. of  $H_3BO_3$  mixed with it, but not greater than that of lactic acid. *Dihydroxymaleic acid* (b) was studied because of its uncertain constitution: it may be considered as an  $\alpha$ -hydroxy- $\alpha$ -ketonic or as a di- $\alpha$ -HO unsatd. acid. In case the latter name represents its constitution it should form a  $H_3BO_3$  complex even at great diln. Certain difficulties were encountered owing to the fact that (b) decomps. into glycolaldehyde and  $CO_2$  at  $25^\circ$ . The soly. of (b) at  $25^\circ$  does not exceed  $1/100$  M. With pyruvic acid the positive effect on  $H_3BO_3$  begins only at  $1/100$  M concns. The results show that the effect of (b) on the cond. of  $H_3BO_3$  is very great and is accentuated by diln., which argues in favor of the di-HO formula. Whether it is truly a maleic or fumaric deriv. could not be detd. Fenton's method (*J. Chem. Soc.* 65, 901(1894)) for preparing dihydroxymaleic acid was modified as follows: 0.004 part of Fe powder was dissolved in a satd. soln. of tartaric acid. The soln. was filtered and cooled with ice. Small portions of 6%  $H_2O_2$  were added from time to time until the color was not perceptibly changed in more than 3 min. after adding  $H_2O_2$ . 10% fuming  $H_2SO_4$  to the extent of 10% of the vol. of the soln. was now added while keeping the temp. below  $10^\circ$ . The mixt. was placed in an ice box and (b) filtered off and washed with cold  $H_2O$  later. The crystals were finely powdered, dissolved in  $H_2O$  previously heated to  $25^\circ$  in a thermostat and the cond. was observed as quickly as possible. The results show that in the presence of  $H_3BO_3$  the increase in cond. is considerable and increases on diln. The velocity of decompn. of (b) at  $25^\circ$  in aq. soln. follows a nearly rectilinear course: in 1 hr. nearly 40% is decompd.  $H_3BO_3$  exercises a positive effect on the cond. of (b), reduces the velocity of decompn. and this in spite of the increase in the  $H^+$  ion concn. In the  $H_3BO_3$  mixt. only 7% (b) is decompd. in the 1st hr. (b) is a stronger acid than oxalic:  $K > 1 \times 10^{-1}$  and the  $H_3BO_3$  complex is one of the strongest organic acids known. Gluconic acid was also examd. to see whether it behaves like the other  $\alpha$ -HO acids. The gradual increase in cond. of aq. solus. of the lactone was followed. The distribution of OH groups in the lactone is not very favorable while with the free acid we have the sum of 2 positive actions: that of the  $\alpha$ -HO acid and of the 4 OH groups. The increase in cond. in the presence of  $H_3BO_3$  is greater than for any  $\alpha$ -HO acid except possibly dihydroxymaleic acid. The velocity of the opening of the lactone ring increases with increasing cond., i. e., with increasing  $H^+$  ion concn. It could not be detd. whether the lactone itself has a positive influence on the cond. of  $H_3BO_3$  or not.

E. J. WITZEMANN.

The influence of boric acid on the conductivity of some optically active  $\alpha$ -hydroxy acids and on their racemates. J. BÖSEKEN AND L. A. VAN DER ENT. Delft. *Rec. trav. chim.* 37, 178-83(1918).—For these expts. *d*- and *dl*-mandelic acid and *d*- and *dl*-tartaric acid were used. The mandelic acid (a) was obtained by the action of KCN on the bisulfite of  $BzH$ . The CN deriv. was hydrolyzed with HCl (*Chem. Ztg.* 90, (1896)). Part of (a) was half neutralized with cinchonine by which the *d*-deriv. was sepd. in some days (*Ber.* 16, 1773(1883); 32, 2388(1899)). The free *d*-acid was liberated in the usual way and purified by crystg. from  $C_6H_6$ . The cond. was detd. as in previous papers (*C. A.* 6, 623; 9, 1766; 10, 1856; 11, 38, 2895). Although the data for *d*- and *dl*-mandelic acid in  $H_3BO_3$  soln. show some difference, it is concluded that the effect on the cond. of  $H_3BO_3$  is equal. The same was found true for *d*- and *dl*-tartaric acid. The effect of (a) is very much greater than that of tartaric acid, which cannot yet be fully explained. It is concluded that the influence of a racemic acid on the elec. cond. of  $H_3BO_3$  is equal to that of its active components.

E. J. WITZEMANN.

The salts of the complex acid, pyrocatechol-boric acid. J. BÖSEKEN with A. OBREIN AND MISS A. VAN HAEFTEN. Delft. *Rec. trav. chim.* 37, 184-94(1918).—B.'s expts. on the influence of various substances on  $H_3BO_3$  have shown that the increase in cond. is caused by an increase in the number of  $H^+$  ions. It is probable

that a complex of these compds. with  $H_2BO_3$  is formed. The behavior of mixts. shows that the complex acids are partly dissociated. Attempts to isolate them in the presence of  $H_2O$  have been fruitless. 2 other ways of obtaining them are available: (1) To allow the  $H_2BO_3$  to react on the poly-HO compd. in non-aq. solns.; (2) to attempt to obtain salts difficultly sol. in  $H_2O$ . In these expts. the 2nd way was used in isolating the  $NH_4$ , K, Rb,  $PhNH_2$ ,  $p\text{-}ClC_6H_4NH_2$  and  $PhNMe_2$  salts of pyrocatechol-boric acid. Analyses show that the compounds are quite complex, ranging with the aluminous and ferripyrocatechol acids (Weinland and Denzel, *C. A.* 8, 1767; Weinland and Binder, *C. A.* 6, 2435). The K,  $NH_4$  and Rb salts are obtained easily when concd. solns. of the 3 compds. are mixed in the proportion of  $H_2BO_3 : C_6H_4(OH)_2 : K((NH_4, Rb)\text{-}OH) = 1:2:1$ . The 3 salts cryst. as white leaves with a silvery luster. The  $NH_4$  complex sublimes without decompn. The complex salts of the organic bases were obtained by mixing concd. solns. of  $H_2BO_3$  (1 part) +  $C_6H_4(OH)_2$  (2 parts) with 1 part of liquid amine. The amines dissolve slowly and the salts later sep. as needles. Only B was difficult to det. analytically. The salt was destroyed in sealed Carius tubes with fuming  $HNO_3$ , the contents were neutralized with a known amt., in excess, of  $CaO$ , the soln. was evapd. and the residue heated to red heat in the electric furnace. The data are given in detail. The results for the  $NH_4$  salt agree with the empirical formula  $(C_6H_4O_2)_2B_2O_4(NH_4)_4$ . For the K salt the result is  $(C_6H_4O_2)_2B_2O_4K_2$  or  $(C_6H_4O_2)_2BO_4H_2K_2$ . For the Rb salt the analytical data point to  $(C_6H_4O_2)_2B_2O_4Rb_2$ . With  $PhNH_2$  the results were not quite certain but appear to conform with  $(C_6H_4O_2)_2B_2O_4(PhNH_2)_2$ . With  $PhNMe_2$  the results conform with  $(C_6H_4O_2)_2BH_2(C_6H_4NMe_2)_2 \cdot 5H_2O$ . With  $p\text{-}ClC_6H_4NH_2$  the formula  $(C_6H_4O_2)_2B_2O_4(ClC_6H_4NH_2)_4 \cdot 4H_2O$  conforms with the analytical results.

E. J. WITZMANN.

The three trichlorobenzenes and their reaction with sodium methylate. A. F. HOLLEMAN. Univ. Amsterdam. *Rec. trav. chim.* 37, 195-204 (1918).—In his study of the action of  $MeONa$  on the nitrodichlorobenzenes de Mooy also studied its action on dichlorobenzenes. He found that  $m\text{-}C_6H_4Cl_2$  is attacked most easily and gives, as do both the others,  $ClC_6H_4OH$ . These expts. have now been extended to the trichlorobenzenes. 1,2,3- $C_6H_3Cl_3$  (a) was prepd. from  $p\text{-}O_2NC_6H_4NH_2$ . 138 g. of the latter were chlorinated (*Rec. trav. chim.* 23, 366 (1904)) by dissolving in 2 l. com.  $HCl$  and adding 82 g.  $KClO_3$ . This soln. was treated at once with  $NaNO_2$ . A mixt. of 170.6 g.  $CuCl_2 \cdot 2H_2O$  in  $H_2O$  with 100 cc.  $HCl$  and 40 g.  $Cu$  powder was boiled until decolorized and added to the diazotized soln. The mixt. was steam distd. and gave considerable (about 136 g.) 1,2,3,5- $C_6H_2Cl_3NO_2$  (b). (b) was reduced as usual with  $Fe$  powder and  $HCl$ ; for 136 g. batches a granite boiler with mechanical stirrer was used. Several hrs. were required after which the soln. was alkalized and distd., giving the corresponding aniline (c). Two ways of converting (c) into (a) were tried. (c) was converted into its corresponding hydrazine and this compd. decompd. with Fehling soln. 98 g. (c) in 250 cc.  $HCl$  were treated with 43 g.  $NaNO_2$  and then with 250 g.  $SnCl_2 \cdot 2H_2O$  in 1 l.  $H_2O$ . The  $PhNHNH_2 \cdot HCl$  formed sepd. in part. The whole mass was then poured into 7.5 l. Fehling soln. and enough alkali added to keep the liquid alk. By steam distn. a poor yield of (a) was obtained. After 2 distns. under reduced pressure the product was white and m.  $52^\circ$ , but turned brown on standing. A stable product was obtained by agitating the ligroin soln. with concd.  $H_2SO_4$ . 1,3,4- $C_6H_3Cl_3$  (d) was obtained according to v. d. Linden (*Rec. trav. chim.* 23, 366 (1904)). In prepg. 1,3,5- $C_6H_3Cl_3$  (e) in order to convert 2,6,4- $Cl_3(O_2N)C_6H_2NH_2$  into 2,6,4- $C_6H_3Cl_3NO_2$  (f) the de Witt diazotization in concd.  $HNO_3$  was used (*Rec. trav. chim.* 23, 366 (1904)). The reduction of (f) was done more easily and the product diazotized gave (e). 100 g. of the aniline in 600 cc. com.  $HCl$  were treated slowly with a concd. soln. of 50 g.  $NaNO_2$ . 110 g.  $CuCl_2$  in 600 cc.  $HCl$  + 54 g. powdered  $Cu$  were heated

until decolorized and added to the cold diazo soln. 65 g. (e) (m.  $63^{\circ}$ ) were sepd. by steam distn. 5.44 g. (a) were heated 7 hrs. at  $180^{\circ}$  with 36 cc. of 0.85 *N* NaOMe. In a 2nd expt. 2 cc.  $H_2O$  were added. On opening the tubes there was no pressure and the contents were still alk. On distg., besides MeOH, a colorless oil was obtained which was dissolved in petr. ether and washed carefully with dil. KOH. The oil was then distd. *in vacuo* and gave white crystals. The residue was treated with steam, acidified and again treated with steam. From the aq. distillate a mixt. of much  $HOC_6H_4Cl_2$  (g) and some dichloroanisole was obtained by extg. Further work on this reaction will be published later by de Lange. On cooling (g), m.  $34-37^{\circ}$ , seps. 2,3- and 2,6- $Cl_2C_6H_3OH$  could be formed from (a). The latter was prepd. according to Chandon (Ber. 16, 1752(1883)) and m.  $65^{\circ}$ . The former, previously unknown, was prepd. by diazotizing 2,3- $Cl_2C_6H_3NH_2$  (C. A. 12, 1542) and m.  $37^{\circ}$ . The product obtained above was a mixt. of these 2 phenols as was shown by sepg. them. Of the 2 the 2,6-deriv. was most acid and was sepd. by partial extn. with a  $Na_2CO_3$  soln. The identification and sepn. of the 2 isomeric anisoles is also described. 5.44 g. (d) were heated 8 hrs. at  $180^{\circ}$  with 30 cc. *N* MeONa. In this case mainly 2,5- $Cl_2C_6H_3OH$ , m.  $57^{\circ}$ , was formed, and only a very small amt. of the anisole. 5 g. (e) heated with 36 cc. 0.85 *N* MeONa for 7 hrs. at  $180^{\circ}$  gave 3.7 g. *sym*- $Cl_2C_6H_3OMe$  as the main product, as well as some phenol. The anisole was identified by hydrolyzing in concd. HCl and sepg. the *sym*- $HOC_6H_3Cl_2$ , m.  $65^{\circ}$ . In order to measure the velocity of reaction of (a), (d) and (e) with NaOMe, 0.9075 g. was heated with 10 cc. 0.5 *N* NaOMe. Similar expts. with  $C_6H_4Cl_2$  isomers required 0.7350 g. for the same amt. of NaOMe. The tubes were heated at  $173-5^{\circ}$  for 3 hrs. Titrations of the Cl showed the following: With *o*- $C_6H_4Cl_2$  0.64% Cl; with the *m*-deriv. 1.66%; with the *p*-deriv. 0.04%; with (a) 27.6%; with (d) 27.7%; with (e) 57.4%. The velocity of reaction of the  $C_6H_4Cl_2$  isomers with NaOMe is many times greater than that of the  $C_6H_3Cl_2$  isomers, or, in other words, the introduction of a 3rd Cl atom causes a great increase in mobility of the atoms

E. J. WITZEMANN.

**The mechanism of the formation of benzophenone according to Friedel and Crafts.** S. C. J. OLIVIER. Wageningen. *Rec. trav. chim.* 37, 205-40(1918).—In previous papers O. (C. A. 8, 3013; 9, 442; 10, 1635, 1854) has made dynamic studies of the formation of various aromatic sulfones in  $C_6H_6$  soln. In the last study referred to abnormalities were found. O. has now studied an analogous reaction in order to extend information on the subject. The following reactions were studied: (1) action of  $BzCl$  on  $C_6H_6$  in presence of  $AlCl_3$  in  $C_6H_6$  soln.; (2) action of  $BzBr$  on  $C_6H_6$  under the influence of  $AlBr_3$  in  $C_6H_6$  soln.; (3) reaction (2) in  $CS_2$  soln. **Reaction 1:** The similar reaction of  $BzCl$  on  $PhMe$  in the presence of  $AlCl_3$  was studied by Steele (*J. Chem. Soc.* 83, 1470) but O. states that the analytical methods used were inexact and the conclusions are to be taken with caution. A careful study of the action of  $BzCl$  on  $C_6H_6$  in presence of  $AlCl_3$  in  $C_6H_6$  soln. seemed justified. The  $AlCl_3$  was prepd. as usual (C. A. 8, 3013). The  $C_6H_6$  used was Merck's thiophene-free product which was dried with  $CaCl_2$ , then Na and fractionated. The  $BzCl$  was specially purified by fractional crystn. All these materials were kept in glass-stoppered bottles in a  $H_2SO_4$  desiccator. The progress of the reaction was measured by detg. the unchanged  $BzCl$  as follows: a known portion of the  $C_6H_6$  soln. containing the reaction products was pipetted off and dropped into 50 cc. dil. alkali containing 3 g. KOH and enough KOH to convert the  $AlCl_3$  present into  $Al(OK)_3$ . This was boiled 1 hr. under a condenser. The  $C_6H_6$  was then removed by heating the acidified soln. The soln. was then extd. with  $Et_2O$  and each ext. washed carefully with  $H_2O$ . The wash  $H_2O$  was returned and extn. continued. The  $Et_2O$  layers were united, evapd., dissolved in 50 cc. 95%  $EtOH$  and the  $BzOH$  was titrated, using phenolphthalein as indicator. Blank expts. showed the results to be satisfac-

tory. The velocity of reaction was detd. as follows: a weighed amt. of powdered  $\text{AlCl}_3$  was placed in a small flask with the  $\text{BzCl}$ . The mol. complex  $\text{BzCl} \cdot \text{AlCl}_3$  (Böese-ken, *Rec. trav. chim.* 19, 19) is formed with the evolution of heat. The requisite amt. of  $\text{C}_6\text{H}_6$  was then added and brought into soln. by agitation in a closed flask. A stopper containing a tube connected with a  $\text{H}_2\text{SO}_4$  wash bottle was fitted to the flask and the latter placed in a thermostat at  $30^\circ$ . After about 10 mins. the 1st sample was taken from the flask and this was used as the beginning of the run. In order to avoid weighing exact amts. of 2 hygroscopic compds. a small excess of  $\text{BzCl}$  was used but the velocity const. was calcd. on the basis of the  $\text{AlCl}_3 \cdot \text{BzCl}$  complex formed, because  $\text{BzPh} \cdot \text{AlCl}_3$  does not give up  $\text{AlCl}_3$  to  $\text{BzCl}$  as was shown by the results. The results show that the reaction is monomol. although there is a slight regular fall in the values. The data for different concns. of  $\text{AlCl}_3$  (0.1 and 0.2 mol.) show that  $K_{0.2}/K_{0.1} = \approx 1.30$ . When excess  $\text{BzCl}$  was used const. for the velocity could be obtained only on the basis of  $\text{AlCl}_3$  present. The excess of  $\text{BzCl}$  was without influence. A  $\text{C}_6\text{H}_6$  soln. of  $\text{BzPh} \cdot \text{AlCl}_3$  (0.2 mol.) was satd. with dry  $\text{HCl}$  gas and kept at  $30^\circ$  for 5 days. On analysis no trace of  $\text{BzCl}$  was found, showing that the reaction  $\text{BzCl} \cdot \text{AlCl}_3 + \text{C}_6\text{H}_6 \rightleftharpoons \text{BzPh} \cdot \text{AlCl}_3 + \text{HCl}$  is not sensibly reversible. The results agree with what was previously found with the aromatic sulfones except in the ratio of  $K_{0.2}/K_{0.1}$ . This might be due to the following dissociation:  $\text{BzCl} \cdot \text{AlCl}_3 \rightleftharpoons \text{BzCl} + \text{AlCl}_3$ . Special expts. in which 1 mol.  $\text{AlCl}_3 + 1$  mol.  $m\text{-O}_2\text{NC}_6\text{H}_4\text{SO}_2\text{Cl} + 1$  mol.  $\text{BzCl}$  were dissolved in  $\text{C}_6\text{H}_6$  and treated as above showed about the same velocity const. as though the  $m\text{-O}_2\text{N} \cdot \text{C}_6\text{H}_4\text{SO}_2\text{Cl}$  were not present. Since  $m\text{-O}_2\text{NC}_6\text{H}_4\text{SO}_2\text{Cl}$  would diminish the concn. of dissociated  $\text{AlCl}_3$ , the const. should be smaller if this dissociation really exists. The reaction products showed much  $\text{BzPh}$  and traces of *m*-nitrodiphenylsulfone. This relation confirms a former observation (C. A. 10, 1635) that  $\text{AlCl}_3$  combines most easily with the acid chloride, which as the addition complex reacts most rapidly with  $\text{C}_6\text{H}_6$  (at  $30^\circ$  for  $\text{BzCl}$   $K_{0.1} = 0.00230$ ; for  $m\text{-O}_2\text{NC}_6\text{H}_4\text{SO}_2\text{Cl}$   $K_{0.1} = 0.000136$ ). In order to study this further the influence of concn. of an excess of the catalyst was studied. For this purpose  $\text{AlBr}_3$  was better suited because of its greater soly. in  $\text{C}_6\text{H}_6$ .

**Reaction II: Action of  $\text{BzBr}$  on  $\text{C}_6\text{H}_6$  in presence of  $\text{AlBr}_3$  in  $\text{C}_6\text{H}_6$  soln.**  $\text{BzBr} \cdot \text{AlBr}_3$  is obtained with the liberation of heat on mixing the components. It is obtained in the pure form as yellow hygroscopic crystals from  $\text{CS}_2$  soln. The velocity of reaction in these expts. was detd. as above since the unchanged  $\text{BzBr}$  could be detd. as  $\text{BzCl}$  was. In a 1st series of expts. it was shown that the velocity of reaction of prepd.  $\text{BzBr} \cdot \text{AlBr}_3$  and mixts. of  $\text{BzBr}$  and  $\text{AlBr}_3$  in  $\text{C}_6\text{H}_6$  is the same. As with  $\text{BzCl}$  the reaction is monomol., showing a slight steady fall in the const. Likewise the ratio  $K_{0.2}/K_{0.1}$  is 1.31 instead of 2 as was found for the sulfone. The velocity of reaction with  $\text{BzBr}$  is considerably greater than with  $\text{BzCl}$ . A series on the effect of temp. showed the ratio  $K_{0.2}/K_{0.1}$  practically unchanged. The temp. coeff. at 0.1 mol.  $\text{AlBr}_3$  was 2.51 for  $40\text{--}30^\circ$ , 2.80 for  $30\text{--}20^\circ$ , 2.91 for  $20\text{--}10^\circ$ , and at 0.2 mol.  $\text{AlBr}_3$  were 2.32, 2.62 and 3.12, resp. These values are normal. Diffuse sunlight was without influence on the velocity of reaction. Excess  $\text{BzBr}$  was without perceptible influence on the velocity of the reaction. The  $\text{AlBr}_3$  mol. transforms but 1 mol.  $\text{BzBr}$  into  $\text{BzPh}$ . The velocity of reaction increases with the concn. of  $\text{BzBr} \cdot \text{AlBr}_3$  but the increase in  $K$  does not keep pace with the concn. proportionally. An excess of  $\text{AlBr}_3$  gives rise to an enormous increase in the velocity of reaction and the excess then acts proportionally to its concn. This might make it appear that of the combined and free  $\text{AlBr}_3$ , the latter is most active. Expts. from which the ratio  $K_{0.2} + K'/K_{0.1} + K'$  was detd., in which  $K'$  was a definite excess of  $\text{AlBr}_3$ , gave the same ratio 1.34 as usual, thus showing that the excess  $\text{AlBr}_3$  has no additional catalytic effect. It appears that the increased velocity of reaction of more concd. solns. of  $\text{BzBr} \cdot \text{AlBr}_3$  may be due to a different degree of association of  $\text{BzBr} \cdot \text{AlBr}_3$ . Cryoscopic measurements on  $\text{BzPh} \cdot \text{AlBr}_3$  in  $\text{C}_6\text{H}_6$  soln. show that it

forms associated mols. easily in which often more than 2 mols. of  $\text{AlBr}_3$  are present.  $\text{BzBr} \cdot \text{AlBr}_3$  probably acts similarly (cf. below). Excess  $\text{AlBr}_3$  combines easily with  $\text{BzPh} \cdot \text{AlBr}_3$  when there is no free  $\text{BzBr}$ . O. suggests that the associated mols.  $(\text{BzBr} \cdot \text{AlBr}_3)_n$  are more active as reacting mols. than less associated or unassociated ones. From this point of view it is not the  $\text{AlBr}_3$  combined with  $\text{C}_6\text{H}_6$  that causes the larger velocity const. in the more concd. solns. This interpretation also explains the gradual diminution in the const. during the course of the reaction. Excess  $\text{BzBr}$  does not combine easily with the  $\text{AlBr}_3$  addition products and so does not influence the reaction. The same interpretation may be used for the chlorides. *Reaction III: The action of  $\text{BaBr}$  on  $\text{C}_6\text{H}_6$  in the presence of  $\text{AlBr}_3$  in  $\text{CS}_2$  soln.:* These expts. were carried out as nearly as possible as before except that the flasks were closed with corks covered with collodion. The  $\text{CS}_2$  used was agitated for some hrs. with  $\text{Hg}$ ,  $\text{HgCl}_2$ ,  $\text{KMnO}_4$  and  $\text{CaCl}_2$  and fractionated. Owing to the  $\text{CS}_2$  the unchanged  $\text{BzBr}$  was detd. by heating 3 hrs. with 40 cc. 12%  $\text{H}_2\text{SO}_4$ , the  $\text{CS}_2$  was evapd., the mixt. was then boiled again for 1 hr. and titrated. The data show that the reaction under these condition ought to be considered to be bimol. In  $\text{CS}_2$  soln. the velocity const. increases with increasing concn. of  $\text{BzBr} \cdot \text{AlBr}_3$ . Moreover, as in  $\text{C}_6\text{H}_6$  soln., an excess of  $\text{AlBr}_3$  causes an enormous increase in the velocity const. Ebullioscopic detns. in  $\text{CS}_2$  soln. showed that  $\text{AlBr}_3$  forms associated mols. but the association does not increase rapidly with the concn. O. suggests that this may be due to the fact that the  $\text{CS}_2$  combines with the  $\text{AlBr}_3$  to give unstable compds. In increasing the concn. the lowering of the b. p. caused by increased association ought to be compensated then by an elevation of the b. p. following the combination of the solvent with the solute. From this point of view the mechanism of the reaction in  $\text{CS}_2$  becomes very complicated. Additional expts. are described from which it is concluded that the amt. of free  $\text{AlBr}_3$  does not det. the velocity of the reaction although excess  $\text{AlBr}_3$  does enormously influence it. O. found that the presence of  $\text{C}_6\text{H}_6$  causes an increase in the association of the  $\text{AlBr}_3$  complex in  $\text{CS}_2$  soln.

E. J. WITZEMANN.

**A reaction of nitrated aromatic compounds.** S. C. J. OLIVIER. Wageningen. *Rec. trav. chim.* 37, 241-4 (1918).—In a preceding paper O. stated that  $m\text{-O}_2\text{NC}_6\text{H}_4\text{SO}_2\text{Cl} \cdot \text{AlCl}_3$ , although a colorless compd., gives an intense orange-red color in  $\text{C}_6\text{H}_6$  soln. (C. A. 10, 1635). On adding  $\text{H}_2\text{O}$  the addition compd. is decompd. and the color disappears. It seemed that nitrated aromatic compds. in general showed this red color when made as follows: The compd. is dissolved in  $\text{C}_6\text{H}_6$  and anhydrous  $\text{AlBr}_3$  is added. That the test is not due to free Br is indicated by the disappearance of the red color on adding  $\text{H}_2\text{O}$ . Further tests showed that all of the following gave the reaction:  $\text{PhNO}_2$ ,  $p\text{-O}_2\text{NC}_6\text{H}_4\text{CONH}_2$ ,  $p\text{-O}_2\text{NC}_6\text{H}_4\text{NH}_2$ ,  $o$ - and  $m\text{-O}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ , as well as the Ba salts,  $m$ -nitrodiphenylsulfone,  $o\text{-O}_2\text{NC}_6\text{H}_4\text{OH}$ ,  $m\text{-C}_6\text{H}_4(\text{NO}_2)_2$  and picric acid: With  $m\text{-O}_2\text{NC}_6\text{H}_4\text{SO}_2\text{Cl}$  it was necessary to use  $\text{AlCl}_3$  instead of  $\text{AlBr}_3$  because of the liberation of Br. After a time nearly colorless crystals sep. and this is accompanied by partial decolorization. In certain cases it is necessary to add excess  $\text{AlBr}_3$  to get the test. The 1st mol.  $\text{AlBr}_3$  combines with the  $\text{SO}_2$  group of the sulfones and the 2nd mol. only is available for the  $\text{NO}_2$  group. This would give rise to 2 products thus:  $m\text{-O}_2\text{NC}_6\text{H}_4\text{SO}_2\text{Ph}$  (colorless) and  $m\text{-O}_2\text{NC}_6\text{H}_4\text{SO}_2\text{Cl}$  (colored). For all the  $o$ -mono-

$\text{AlCl}_3$

$\text{AlCl}_3$

$\text{NO}_2$  compds. examd. it is necessary to use a small amt. of  $\text{AlBr}_3$  in order to obtain the orange-red color. If more is used, e. g., with  $o\text{-C}_6\text{H}_4(\text{NO}_2)_2$ , the soln. becomes brown or black and colored products are obtained on adding  $\text{H}_2\text{O}$ . The reaction is not obtained so characteristically with nitroaliphatic compds. (nitroguanidine). The  $\text{C}_6\text{H}_6$  plays an essential role in the reaction.  $\text{CS}_2$  could not be used for  $\text{C}_6\text{H}_6$  in most cases.

E. J. WITZEMANN.

**The formation and the decomposition of some halogenated organic compounds.**

EINAR BRILMANN. Univ. Copenhagen. *Rec. trav. chim.* 37, 245-50(1918).—In a preceding paper (*C. A.* 11, 3037) it was demonstrated that the reduction of dibromopropionic acid into acrylic acid by the action of KI in H<sub>2</sub>O takes place as follows:  $\text{CH}_2\text{BrCHBrCO}_2\text{H} + 3\text{KI} \longrightarrow \text{CH}_2\text{:CHCO}_2\text{H} + 2\text{KBr} + \text{KI}_2$ . The KI<sub>2</sub> does not react with the acrylic acid. The reaction gave good consts. for a bimol. reaction, when the free I<sub>2</sub> at various stages was titrated with Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>. 0.1 mol. dibromopropionic acid + 0.3 mol. KI per l. were dissolved in 1.0 N H<sub>2</sub>SO<sub>4</sub> and the rate of formation of I at 53° detd. The results calcd. on the bimol. formula gave  $K_{25} = 0.0711$ . The const. previously detd. at 25° was  $K_{25} = 0.0220$ . The temp. coeff. for this reaction 0.0711/0.0220 is therefore 3.23. Expts were made with dibromosuccinic acid (a) on the supposition that the reaction would be  $(\text{CHBr.CO}_2\text{H})_2 + 3\text{KI} \longrightarrow (\text{:CHCO}_2\text{H})_2 + 2\text{KBr} + \text{KI}_2$ . A more dil. soln. of (a) was used because of its smaller soly. The velocity const. by the bimol. formula ( $1/40$  mol. (a) +  $1/40$  mol. KI per l. in 1.0 N H<sub>2</sub>SO<sub>4</sub>) at 25° is  $K_{25} = 0.0143$ . At 35°  $K = 0.0388$ . The temp. coeff. of this reaction is accordingly 2.69. A comparison of the behavior of (a) and isodibromosuccinic acid (b) was of interest. B. found that the reaction of (b) with KI is slow while the hydrolysis with the formation of HBr is fast so that const. values for K could not be obtained as with (a). These results coincide with those of Holmberg (*C. A.* 6, 74) with K xanthogenate. The product with both (a) and (b) is fumaric acid. Benzylbromomalononic acid reacts thus:  $\text{PhCH}_2\text{CBr}(\text{CO}_2\text{H})_2 + 3\text{KI} + \text{H}_2\text{O} \longrightarrow \text{PhCH}_2\text{CH}(\text{CO}_2\text{H})_2 + \text{KI}_2 + \text{KBr} + \text{KOH}$ , and may be followed by titrating I or KOH. The velocity const. could not be detd.

E. J. WITZEMANN.

**The nonformation of an *o*-tolylhydrazone of lactose, an affirmation of its molecular structure and its indirect identification.** A. W. VAN DER HAAR. Utrecht. *Rec. trav. chim.* 37, 251-3(1918).—In a preceding paper *o*-tolylhydrazine (*C. A.* 12, 1543) was described as a specific reagent for *d*-galactose. Only *d*-galactose gives a cryst. colorless hydrazone, while *l*-arabinose, xylose, rhamnose, fucose, *d*-glucose, *d*-mannose and *d*-fructose do not do so. It therefore seemed important to study the behavior of *o*-tolylhydrazine with di- and trisaccharides. Non-reducing disaccharides like sucrose and trehalose which lack the partial configuration of *d*-galactose as well as the free CO group do not give *o*-tolylhydrazones. Raffinose, although it contains the partial configuration has no free CO group and does not give an *o*-tolylhydrazone. Maltose, although a reducing sugar having a free CO group but not the partial configuration of galactose, does not form the *o*-tolylhydrazone. Lactose containing the galactose configuration and the free CO group of a reducing sugar also fails to give an *o*-tolylhydrazone. From this v. d. H. concludes that the free CO group of the *d*-galactose configuration is fixed while only that with *d*-glucose configuration functions in lactose. This confirms the mol. structure assigned to lactose by Fischer (*Ber.* 26, 2400(1893)). *d*-Galactose mixed with lactose was easily detected with *o*-tolylhydrazine. 0.400 g. lactose were hydrolyzed in 10 cc. 2% H<sub>2</sub>SO<sub>4</sub>. The soln. was neutralized with excess BaCO<sub>3</sub>, the liquid filtered, evapd. to a sirup and mixed with an equal amt. of H<sub>2</sub>O and 5 cc. 95% EtOH. After heating 0.5 hr. on the water bath with 0.400 g. *o*-tolylhydrazine 0.030 g. of the *d*-galactose *o*-tolylhydrazone sepd. after 48 hrs. In this indirect way lactose may be distinguished from the other polysaccharides that do not contain the *d*-galactose group.

E. J. WITZEMANN.

**Direct rupture of the benzene ring without degradation.** II. H. PAULY AND G. WILL. *Ann.* 416, 1-20(1918); *J. Chem. Soc.* 114, I, 525-6; cf. Pauly, Gilmore and Will (*C. A.* 8, 1736).—P. and W. have already shown that when 3-nitro-*p*-cresol is warmed with concd. H<sub>2</sub>SO<sub>4</sub>, NH<sub>2</sub>OH and β-methyl-γ-crotonolactone-γ-acetic acid (a),

$\text{O.CO.CH:CMc.CHCH}_2\text{CO}_2\text{H}$ , are formed, and they have suggested the immediate precursor of the lactonic acid is  $\beta$ -methylmuconic acid (*b*),  $\text{HO}_2\text{CCH:CHCMc:CHCO}_2\text{H}$ . It is now shown that the latter acid can be prepd. from the lactone and easily reconverted into it. The optimum temp. for the above hydrolytic rupture is  $111-3^\circ$ . The nitrogenous acid by-product reacts very slowly with  $\text{MeOH-HCl}$  compared with the lactonic acid and a sepn. of the acids is best effected by taking advantage of this fact. The Me ester of the lactonic acid (now called *isoprenelactonic* or  $\beta$ -methylmuconolactonic acid), *b*,  $310^\circ$ , and is hydrolyzed by treatment with  $\text{MeONa}$  to methyl hydrogen  $\beta$ -methylmuconate (*isoprenedicarboxylate*), which forms needles, *m.*  $125^\circ$ . This is converted into the free acid (*b*), *m.*  $171^\circ$ , by hydrolysis with  $\text{NaOH}$ , and into the di-Me ester, long, glistening needles, *b*,  $142-143^\circ$ , *m.*  $38.5^\circ$ , by means of  $\text{Me}_2\text{SO}_4$ . The acid resembles muconic acid in forming very sparingly soluble barium, silver and lead salts, and the methyl ester, like isoprene, changes in the course of time into a pale, elastic polymeride. The corresponding diamide, *m.*  $213-4^\circ$ , and becomes deep bluish green when kept molten for a few minutes; methyl  $\beta$ -methyl muconamate forms stout prisms, *m.*  $161-2^\circ$ , and the vapors obtained by heating it with  $\text{Zn}$  dust give the pyrrole reactions. The reconversion of the di- $\text{CO}_2\text{H}$  acid into the lactonic acid can be effected by means of warm  $\text{H}_2\text{SO}_4$ , glacial  $\text{AcOH}$  solns. of  $\text{HCl}$  or  $\text{HBr}$ , or by melting. Similarly, the above Me H ester yields the Me ester of the lactonic acid when heated at  $210^\circ$ . The di- $\text{CO}_2\text{H}$  acid is most readily reduced by  $\text{Na-Hg}$ , the product being  $\beta$ -methyl- $\Delta^{\beta}$ -butene- $\alpha,\delta$ -dicarboxylic acid,  $\text{HO}_2\text{C.CH}_2\text{CMc:CHCH}_2\text{CO}_2\text{H}$ . This was prepd. previously from the lactonic acid and designated  $\beta$ -methylidihydromuconic acid, but the position of the ethylene linking remained to be proved. The acid, *m.*  $140-1^\circ$ , couples with diazonium salts, which, from analogy to glutamic acid, shows that the double bond is in the middle of the chain. The methyl ester is a limpid liquid with the odor of melons, *b*,  $245^\circ$ ,  $d_{20}^{20}$  1.0824, and yields  $\text{AcCH}_2\text{CO}_2\text{Me}$  when its ozonide is boiled with  $\text{H}_2\text{O}$ , this fact also attesting to the position of the ethylene linking. The free (*b*) reacts vigorously with  $\text{Br}$ ,  $\text{HBr}$  being evolved, but its Me ester absorbs 4 atoms of  $\text{Br}$  fairly readily. The above butenedicarboxylic acid also absorbs  $\text{Br}$  at  $40-50^\circ$ , giving  $\beta,\gamma$ -dibromo- $\beta$ -methyladipic acid,  $\text{HO}_2\text{C.CH}_2\text{CMcBrCHBrCH}_2\text{CO}_2\text{H}$ , *m.*  $166^\circ$ , which is decompd. by boiling  $\text{EtOH-KOH}$ , the products including isoprene and (*b*).

C. J. WEGST

**Naphthasultam.** III. Nitro and amino derivatives of naphthasultam and hydrolytic products of tetrachloroketotetrahydronaphthasultam (2,2,3,3-tetrachloro-1,8-naphthasultam-4-quinone). TH. ZINCKE AND GRETE SCHÜRMANN. *Ann.* 416, 65-85 (1918); *J. Chem. Soc.* 114, I, 550-1; cf. *C. A.* 11, 1403. The analogy between 1,8-naphthasultam and  $\alpha$ - $\text{C}_{10}\text{H}_7\text{OH}$  is also exhibited by their  $\text{O}_2\text{N-}$  and  $\text{H}_2\text{N-}$ derivs. When 1,8-naphthasultam is ground with  $\text{HNO}_3$  (d. 1.2; 10 parts) it yields 2,4-dinitro-1,8-naphthasultam,  $\text{C}_{10}\text{H}_5\text{O}_4\text{N}_2\text{S}$ , in brownish yellow tablets and prisms, *m.*  $258^\circ$  (decompn.) and forms deep yellow cryst. ammonium, potassium and sodium salts. Dannerth (*J. Am. Chem. Soc.* 29, 1319) regarded the product as a mono- $\text{NO}_2$  deriv. On reduction with  $\text{Sn}$  and  $\text{HCl}$  the compd. gives 2,4-diamino-1,8-naphthasultam, slender, yellow needles, which soon become dark on exposure to the air; monohydrochloride, yellow needles; dihydrochloride, pale yellow needles; triacetate, needles, *m.* above  $270^\circ$ , which changes into 2,4-diacylamino-1,8-naphthasultam,  $\text{C}_{14}\text{H}_{15}\text{O}_4\text{N}_2\text{S}$ , when shaken with dil. alkali hydroxides. The  $\text{HCl}$  salts are oxidized by  $\text{FeCl}_3$  to 2-amino-1,8-naphthasultam-4-quinoneimide (I), a reddish brown powder, which darkens at  $230-5^\circ$ , and forms a hydrochloride, dark red needles. The imide reacts with  $\text{PhNH}_2$  in hot alc.  $\text{AcOH}$  to give 2-anilino-1,8-naphthasultamquinoneanil,  $\text{C}_{22}\text{H}_{19}\text{O}_4\text{N}_3\text{S}$ , which crystals in bronzy red needles, *m.*  $235-6^\circ$  and forms an almost black hydrochloride and nitrate. 2,2,3,3-Tetrachloronaphthaquinone and 2,3,2,3-tetrachloro-1,8-naphthasultam-4-quinone re-

$\text{H}_2\text{S}$ )<sub>2</sub>O in its reactions. Esters of the sulfinous acid,  $\text{O}_2\text{NC}_6\text{H}_4\text{ClSOR}$ , are obtained by the action of alc. or  $\text{Et}_2\text{O}$  solns. of the Na alkyl or aryl oxides; *methyl ester*, golden leaflets, m.  $111-2^\circ$ ; *ethyl ester*, yellow needles, m.  $73-4^\circ$ ; *phenyl ester*, nodules of stout, yellow needles, m.  $75^\circ$ . *4-Chloro-2-nitrobenzenesulfinic acid*,  $\text{O}_2\text{NC}_6\text{H}_4\text{ClSO}_2\text{H}$ , slender, glistening leaflets, m.  $127^\circ$  (decompn.), is prepd. by shaking the chlorothiols with 2 N NaOH and acidifying the filtrate. Its Ag salt reacts with MeI to form the *methyl ester*, m.  $143^\circ$ , and with the chlorothiol, to give *4,4'-dichloro-2,2'-dinitrodiphenyl disulfide*,  $\text{S}_2\text{O}_2(\text{C}_6\text{H}_3\text{ClNO}_2)_2$ , needles, m.  $145^\circ$ . The chlorothiol reacts with  $\text{NH}_3$  in  $\text{CHCl}_3$  soln. to give *4-chloro-2-nitrophenylthiolamine*,  $\text{O}_2\text{NC}_6\text{H}_4\text{ClSNH}_2$ , glistening, yellow leaflets, m.  $126-7^\circ$ , and resembles the corresponding *o*-compd. It forms a *benzylidene compound*, long, yellow needles, m.  $161^\circ$ , and when boiled with 50% AcOH, changes into *4,4'-dichloro-2,2'-dinitrodiphenyldithiolamine*,  $\text{NH}(\text{SC}_6\text{H}_3\text{ClNO}_2)_2$ , slender, pale yellow needles, m.  $210^\circ$  (decompn.). Towards phenols the chlorothiol behaves like a diazonium chloride; PhOH gives *4-chloro-2-nitro-4'-hydroxydiphenyl sulfide*, yellow needles, m.  $130^\circ$ ;  $\alpha\text{-C}_{10}\text{H}_7\text{OH}$  forms *4-chloro-2-nitrophenyl-2'- $\alpha$ -hydroxynaphthyl sulfide*,  $\text{O}_2\text{NC}_6\text{H}_4\text{ClSC}_{10}\text{H}_6\text{OH}$ , small, yellow tablets, m.  $154-5^\circ$ ;  $\beta\text{-C}_{10}\text{H}_7\text{OH}$  yields a *sulfide*, which crysts. in orange-yellow needles, m.  $185^\circ$ . The thiol also condenses with ketones. AcMe yields *4-chloro-2-nitrophenylthioacetone*,  $\text{O}_2\text{NC}_6\text{H}_4\text{ClSCH}_2\text{COMe}$ , yellow leaflets or broad needles, m.  $114-5^\circ$ ; BzMe gives *phenyl 4-chloro-2-nitrophenylthio-methyl ketone*, pale yellow needles, m.  $155^\circ$ , which is oxidized by  $\text{HNO}_3$  to BzH and  $\text{S}_2\text{O}_2(\text{C}_6\text{H}_3\text{ClNO}_2)_2$ .  $\text{AcCH}_3\text{CO}_2\text{Et}$  or its Cu compd. forms *ethyl 4-chloro-2-nitrophenylthioacetate*,  $\text{O}_2\text{NC}_6\text{H}_4\text{ClSCHAcCO}_2\text{Et}$ , pale yellow tablets, m.  $129-30^\circ$ , decomp.  $170^\circ$ .  $\text{Ac}_2\text{CH}_2$  yields *diacetyl-4-chloro-2-nitrophenyldithiolmethane*,  $\text{O}_2\text{NC}_6\text{H}_4\text{ClSCHAc}_2$ , brilliant yellow, large needles, m.  $116-7^\circ$ . Upon oxidation these compds. yield sulf-oxides; the compound  $\text{O}_2\text{NC}_6\text{H}_4\text{ClSOCH}_2\text{Bz}$  forms pale yellow needles, m.  $144^\circ$ , and the compound,  $\text{O}_2\text{NC}_6\text{H}_4\text{ClSOCHAcCO}_2\text{Et}$ , stout, yellow tablets, m.  $111^\circ$ . They may also be reduced by  $\text{SnCl}_2$ , but the products are thiazine derivs., and not amines. They sep. as chlorostannates. *6-Chloro-3-phenyl-1,4-benzothiazine*, crysts. in pale yellow,

glistening tablets, m.  $64^\circ$ , and forms orange or red salts with mineral acids, these being decompd. by  $\text{H}_2\text{O}$ . The thiazine changes in a few days into a mixt. of 2 compds., m.  $178^\circ$  and  $214^\circ$ ; the change also proceeds in soln., AcOH favoring the compd. with the higher m. p., and  $\text{CHCl}_3$  the other. The constitution is elucidated by the fact that the thiazine may be synthesized by the action of  $\text{C}_6\text{H}_5\text{COCH}_2\text{Br}$  on *4,2*-Cl( $\text{H}_2\text{N}$ )- $\text{C}_6\text{H}_3\text{SH}$ . *Ethyl 6-chloro-3-methyl-1,4-benzothiazine-2-carboxylate* crysts. in glistening, orange-red tablets or stout needles, m.  $177-8^\circ$ .

**Behavior of thymic acid to phenylhydrazine.** R. FEULGEN AND G. LANDMANN. *Z. physiol. Chem.* 102, 262-5 (1918); *J. Chem. Soc.* 114, I, 554-5.—Further evidence of the existence of 2 free CHO groups in thymic acid is furnished by the prepn. of a diphenylhydrazone of the acid, which is isolated in the form of its Ba salt. Ba thymate is dissolved in  $\text{H}_2\text{O}$  and treated at  $60^\circ$  with  $\text{PhNHNH}_2$  in AcOH. The temp. is then raised to  $100^\circ$ , and the heating continued for 20 min.  $\text{Ba}(\text{AcO})_2$  is added and then 3 vol. of boiling alc. After cooling, the pptd. phenylhydrazone is purified by repptn. by alc. from dil. AcOH. *Barium phenylhydrazinotymate*,  $\text{C}_{40}\text{O}_{38}\text{O}_{24}\text{N}_4\text{P}_2\text{Ba}_2$ , is a yellow, amorphous substance which readily decomp. when heated or treated with strong acids. Cryst. derivs. have not been obtained.  
C. J. WEST.

The hydrate and alcoholate of calcium benzoate. FREDRICK STANBRIDGE. *J. Chem. Soc.* 113, 808-16(1918).— $\text{Ca}(\text{OBz})_2 \cdot 3\text{H}_2\text{O}$  when completely dehydrated and then treated with alc., forms a *dialcoholate* of the formula  $\text{Ca}(\text{OBz})_2 \cdot 2\text{EtOH}$ . This salt is unstable. On the other hand, the trihydrate when treated with an excess of strong alc. is partially dehydrated and a *monohydrate*,  $\text{Ca}(\text{OBz})_2 \cdot \text{H}_2\text{O}$ , is formed. Soly. measurements of the trihydrate at a temp. range of  $0.2-85^\circ$  were made and these also point to the existence of a lower hydrate, probably the monohydrate. The transition temp. was found to be  $84.7^\circ$ , and the soly. 7.62 g. of  $\text{Ca}(\text{OBz})_2$  per 100 g. of  $\text{H}_2\text{O}$ . A study of the f. ps. of solns. of  $\text{Ca}(\text{OBz})_2$  showed that the cryohydric point is  $-0.37$  when the soln. contains 2.22 g. of  $\text{Ca}(\text{OBz})_2$  per 100 g. of  $\text{H}_2\text{O}$ . MAX PHILLIPS.

Hydrogenation of aromatic compounds with the aid of platinum. III. Hydrogenation with platinum containing oxygen. RICHARD WILLSTÄTTER AND DANIEL JAQUET. *Akad. Wiss. München. Ber.* 51, 767-79(1918); cf. *C. A.* 7, 1508.—Certain reductions, like that of phthalic anhydride (*a*), which cannot be effected catalytically with Pt free from O, can be initiated by loading the Pt with O and brought to completion by again treating the Pt with O as the catalyst gradually loses its O by the formation of  $\text{H}_2\text{O}$ . Oxygen-free Pt and that containing O behave like 2 different contact substances in reduction processes. Thus, 20.3 g. (*a*) in 75 cc. glacial AcOH with 5 g. Pt absorbed only 400 cc. H; if, however, the H gasometer was shut off and the reaction bulb evacuated, then allowed to fill with air, shaken 1 min. (whereupon O was rapidly absorbed—about 5 cc. per g. Pt) and the air was driven out with H, about 500 cc. of H was again absorbed after each such activation until the 20th and 21st times, when the absorption of H was 1230 and 5600 cc., resp. The total absorption was 17040 cc. ( $20^\circ$ , 760 mm.) or, deducting about 1150 cc. used up by the O introduced in the activations, 15890 cc. or 4.8 mols. Of the 2 rings in (*a*) the 5-membered one is reduced before the  $\text{C}_6\text{H}_4$  ring; the first product is phthalide (*b*) which is partially reduced to hexahydrophthalide (*c*) and partially to *o*- $\text{MeC}_6\text{H}_4\text{CO}_2\text{H}$  (*d*) which is then reduced to the hexahydrotoluic acid (*e*). If the process is interrupted when only a little H has been absorbed there is obtained, besides some  $\text{C}_6\text{H}_5(\text{CO}_2\text{H})_2$ , a mixt. of (*b*) and (*c*), and while (*b*) is easily reduced further to (*d*), (*c*) cannot be reduced to (*e*). If in the process of isolation alkali is employed the (*c*) is in part obtained as methylolhexahydrobenzoic acid. Among the reduction products is also *cis*-hexahydrophthalic acid (*f*). In the reduction described above were obtained 7 g. (*c*) (partially hydrolyzed), 7 g. (*e*) and 4 g. (*f*). In a similar reduction of (*b*) 3.4 mols. H were absorbed and there were obtained about equal parts of (*e*) and (*c*). Phthalimide behaves quite differently from (*a*) on reduction, the aromatic nucleus and not the CO groups taking up the O. The activation of the Pt with O is not necessary but the reduction is successful only with the best Pt sponge preps.; many which were active towards  $\text{C}_6\text{H}_6$  were inactive towards the imide. Nor can MeOH, EtOH or cyclohexane be used as a solvent; in glacial AcOH the reduction proceeds smoothly. *cis*-Hexahydrophthalimide seps. from  $\text{H}_2\text{O}$ , alc. and AcOH in monoclinic prisms, m.  $132^\circ$ . Naphthalic acid purified by crystn. from alc. cannot be reduced because it always contains some anhydride (*g*) but the acid freshly pptd. from alk. soln. can be reduced; contrary to  $\text{C}_{10}\text{H}_8$ , it takes up only 4 atoms of H; the tetrahydronaphthalic acid (*h*) seps. in cube-like prisms, m.  $196^\circ$  with loss of  $\text{H}_2\text{O}$  and conversion into the anhydride, m.  $119^\circ$ . (*g*), like (*a*), can be reduced only with Pt activated with O; after about 4 mols.  $\text{H}_2$  have been absorbed the reaction slows up. As far as the (*g*) itself is reduced, the anhydride ring is attacked, but as some of the (*g*) is hydrolyzed by the  $\text{H}_2\text{O}$  formed, some (*h*) is obtained. Among the reduction products are tetrahydro-1-methylnaphthalene-8-carboxylic acid (*i*), tetra- and decahydronaphthalides and a small amt. of decahydroacenaphthene. The 2 naphthalides could not be isolated pure. The (*i*) seps. from  $\text{Et}_2\text{O}$ -petr. ether in

needles, m.  $150^{\circ}$ .  $o$ - $C_6H_4(CO_2H)_2$  is easily reduced in AcOH when entirely free from the anhydride, yielding exclusively the *cis*-hexahydro acid, m.  $191-2^{\circ}$ . The *p*-acid in AcOH suspension is reduced much more rapidly on gentle warming, giving about equal parts of the *cis*- and *cis-trans*-hexahydro acids, m.  $162-3^{\circ}$  and about  $300^{\circ}$ , resp. The *m*-acid, if pure, is likewise easily reduced in AcOH suspension, forming chiefly the *cis*- and some *cis-trans*-hexahydro acid. *p*-Toluylic acid very quickly gives exclusively or almost exclusively the liquid hexahydro acid whose amide m.  $175-6^{\circ}$ . Indole in AcOH smoothly absorbs 8 atoms H with formation of *perhydroindole*, b<sub>m</sub>  $182-3^{\circ}$ , b<sub>11</sub>  $65^{\circ}$ , a basic oil of medium consistency and unpleasant, penetrating, onion-like odor,  $d_4^{20}$  0.9947; *chloroplatinate*, reddish yellow monoclinic tablets from alc., m.  $172-3^{\circ}$  (not sharply); *picrate*, fine needles from alc., m.  $137-8^{\circ}$  (not sharply). If the reduction is interrupted before it is complete (e. g., when 2 atoms of H have been absorbed), the product contains unchanged indole, dihydroindole and perhydroindole, the last being removed by shaking the Et<sub>2</sub>O soln. with 0.1 *N* HCl until the alk. reaction just disappears, and the first two being sepd. by fractional pptn. from Et<sub>2</sub>O with picric acid.

CHAS. A. ROUILLER.

**Isolation of dyes with picric acid and dichloropicric acid.** RICHARD WILLSTÄTTER AND GUSTAV SCHUDEL. Akad. Wiss. München. Ber. 51, 782-8 (1918).—The method of isolation of dyes occurring in nature based on the partition of the oxonium dyes between H<sub>2</sub>O and AmOH (C. A. 12, 1404) is not applicable to glucosidal dyes, but the use of the picrates of these dyes makes possible a methodical advance in this field. These dyes, which are easily sol. in H<sub>2</sub>O but insol. in Et<sub>2</sub>O and other solvents immiscible with H<sub>2</sub>O, can be transformed by means of picric acid from their aq. solns. into organic solvents. The method is applicable to the isolation of anthocyanins and other basic dyes of different classes. Thus fuchsin and parafuchsin can be quant. transferred from H<sub>2</sub>O to Et<sub>2</sub>O. Of the anthocyan dyes, when picric acid is added to solns. of their chlorides, anthocyanidines go over quant. into Et<sub>2</sub>O while monoglucosides (like chrysanthemin) and diglucosides (like cyanin) do not pass at all into alc.-free Et<sub>2</sub>O, but with suitable solvents the picrates of the glucosidal dyes can also be removed from aq. solns. Below are the partition nos. (% of dyes removed from H<sub>2</sub>O by the given solvent) of the picrates of mono- and diglucosides, resp.: Et<sub>2</sub>CO, about 50, 0; AmOH, 80-90, about 30; 2 parts AmOH + 1 part BzMe, 100, 70-80. Et<sub>2</sub>CO thus affords a good means of sepg. mono- and diglucosides, and carvone, in which the picrates are more sol., is even better for work with large amts., while with AmOH + BzMe dyes like cyanin can be extd. from aq. solns. such as fruit juices. For practical purposes, however, the picrates are in general not sol. enough in these solvents, and in this respect the dichloropicrates are more suitable. The partition nos. of the mono- and diglucoside dichloropicrates, resp., are as follows: Et<sub>2</sub>O, 40, about 3; Et<sub>2</sub>CO, almost 100, about 60; AmOH, 100, about 90; 2 parts AmOH + 1 part BzMe, 100, 100. By this means, fuchsin, parafuchsin and methylene blue can be completely transferred to Et<sub>2</sub>O, safranin to Et<sub>2</sub>CO. The prepn. of the reagent is described:  $p\text{-O}_2\text{NC}_6\text{H}_4\text{NH}_2 + \text{Cl}$  (Flürscheim, C. A. 3, 885)  $\rightarrow$  2,6,4-Cl(O<sub>2</sub>N)<sub>3</sub>C<sub>6</sub>H<sub>2</sub>NH<sub>2</sub> (yield, almost quant.) + HNO<sub>2</sub> (Holleman, Rec. trav. chim. 23, 366 (1904))  $\rightarrow$  3,5-Cl<sub>2</sub>C<sub>6</sub>H<sub>2</sub>NO<sub>2</sub> (yield, 82-3%) + Fe + HCl (Holleman, Rec. trav. chim. 25, 186 (1906))  $\rightarrow$  Cl<sub>2</sub>C<sub>6</sub>H<sub>2</sub>NH<sub>2</sub>. Blankensma's method for the conversion of the last into Cl<sub>2</sub>C<sub>6</sub>H<sub>2</sub>OH (C. A. 2, 1133) gives unsatisfactory yields. The product contains large amts. of 4-[3',5'-dichlorobenzeneazo]-3,5-dichlorophenol (a), the 2,4-diazo compound (b) and 4-nitroso-3,5-dichlorophenol (c). The mixt., after being boiled, is dissolved in Et<sub>2</sub>O, which leaves behind a part of the (b), the Et<sub>2</sub>O evapd., the residue dissolved in C<sub>6</sub>H<sub>6</sub> and the C<sub>6</sub>H<sub>6</sub> soln. shaken with very dil. NaOH, (b) remaining quant. in the C<sub>6</sub>H<sub>6</sub> as the Na salt. The aq. alk. soln. yields the (a) as the Na salt to Et<sub>2</sub>O while in the H<sub>2</sub>O there remain the phenol and

(c), sepd. by crystn. from petr. ether. (a), prepd. from its components in soda soln., sepa. from dil. alc. in silky, flat, brown-red prisms, m.  $191-2^{\circ}$ ; sodium salt, yellow prisms from NaOH, quant. extd. from 20% NaOH by  $\text{Et}_2\text{O}$ . (b) forms long orange needles, m.  $260-1^{\circ}$ . (c), from  $\text{C}_6\text{H}_5\text{ONa} + \text{NaNO}_2 + \text{H}_2\text{SO}_4$ , fine, very faintly greenish yellow prisms from  $\text{H}_2\text{O}$ , m.  $150-1^{\circ}$ .  $3,5\text{-Cl}_2\text{C}_6\text{H}_3\text{OH}$ , m.  $68^{\circ}$ , is obtained in 39.6 g. yield by stirring 54 g.  $\text{Cl}_2\text{C}_6\text{H}_3\text{NH}_2$  with 150 cc.  $\text{H}_2\text{SO}_4$  and 660 cc.  $\text{H}_2\text{O}$  to a paste, treating with stirring with 23 g. powdered  $\text{NaNO}_2$ , filtering when the reaction is complete and dropping into a vigorously boiling mixt. of 900 g.  $\text{H}_2\text{SO}_4$ , 500 g.  $\text{H}_2\text{O}$  and 600 g. anhydrous  $\text{Na}_2\text{SO}_4$  connected with a condenser, the distg. temp. being  $145-55^{\circ}$  and the addition of the soln. so regulated that the vol. of the liquid remains about constant. The phenol is isolated from the distillate by salting out and extg. with  $\text{Et}_2\text{O}$ ; 81.5 g. in 4 parts glacial AcOH is slowly added to 326 g. red fuming  $\text{HNO}_3$ , warmed 45 min. to  $70^{\circ}$ , moderately dild., made alk. with KOH, filtered, washed, decompd. with 2 N  $\text{H}_2\text{SO}_4$ , extd. with  $\text{Et}_2\text{O}$  and repeatedly washed with  $\text{H}_2\text{SO}_4$  until free from K; there is thus obtained about 90 g. of dichloropicric acid,  $3,5,2,4,6\text{-Cl}_2(\text{O}_2\text{N})_2\text{-C}_6\text{OH}$ , pale yellow prisms from AcOH, m.  $139-40^{\circ}$ ; 10 cc. of the satd. aq. soln. at  $19.7^{\circ}$  contains 0.74 g. acid, 0.74 g. Na salt, 0.055 g. K salt. The salts are lemon-yellow, the K salt forming fine needles, the Na salt 4-sided prisms. C. A. ROUILLER.

Degradation of starch by formaldehyde. H. MAGGI AND G. WOKER. Univ. Bern. *Ber.* 51, 790-3(1918); cf. C. A. 12, 1192.—The ppts. which, as described in earlier papers, M. and W. obtained by adding 96% alc. to the concd. dialyzates of their starch-HCHO mixts. and which they then considered to be dextrin, were redissolved in  $\text{H}_2\text{O}$  and allowed to stand about 2 months; there was an abundant growth of some as yet unidentified mold, and the strongly reducing filtrate from this yielded glucosazone. This same mold was found, by expt., to be able to convert dextrin into glucose, and the view expressed in the earlier papers that the dialyzable product formed in the starch-HCHO mixts. in dextrin is confirmed. A control expt. with  $\text{HCO}_2\text{H}$  showed that it is not the  $\text{HCO}_2\text{H}$  in the HCHO which breaks down the starch. C. A. R.

Nitrate and nitrite assimilation. XIII. Iron and oxygen as necessary agents for the reduction of alkali nitrites with autooxidizable compounds. OSKAR BAUDISCH. Beiersdorf & Co., and Eppendorfer Krankenhaus, Hamburg. *Ber.* 51, 793-805(1918); cf. C. A. 11, 2906.—The formation of hyponitrous acid (*Stickstoffsäure*),  $\text{HNO}$ , as a labile intermediate product in nitrate and nitrite reduction had thus far been definitely shown only in photochem. reactions (C. A. 5, 2826). It has now been found, however, that if 5 g. dextrose, 0.5 g.  $\text{FeSO}_4$  and 5 g.  $\text{NaHCO}_3$  in 150 cc. boiling distd.  $\text{H}_2\text{O}$  in a  $\text{CO}_2$  atm. are treated with 5 g.  $\text{KNO}_3$  the clear distillate gives no color with  $\text{FeCl}_3$  but if HCHO is added to the distg. flask the intense hydroxamic acid-Fe reaction can soon be obtained in the distillate. This reaction is not obtained in the first distillate on addition of HCHO; the exceedingly unstable  $\text{HNO}$  can be identified only if HCHO is added to the reaction mixt.  $\text{HCHO} + \text{HNO} = \text{HC}(\text{:NOH})\text{OH}$ . Like aldo- and keto-hexoses, so also pentoses, trioses and glycolaldehyde in the presence of  $\text{Fe}'$  and  $\text{Fe}''$  salts reduce only alkali nitrites and not the nitrates. Thus,  $\text{CO}(\text{CH}_2\text{OH})_2$  or acetol in soda boiled with a little  $\text{FeCl}_3$  forms brown-red soln. with violet tinge which reduces  $\text{KNO}_3$  intensely to  $\text{NH}_3$  but does not attack  $\text{KNO}_3$ . With the trioses it was again found that only aldoses and ketoses possess reducing power, the formation of  $\text{PhNH}_2$  from  $\text{PhNO}_2$  being used in this case as the indicator of reducing power; the Fe was supplied in complex combination—a few cc. of the violet-red soln. of 1 g. pyrocatechol-*o*-carboxylic acid (a) and 5 g. soda in 250 cc.  $\text{H}_2\text{O}$  and 10 drops of  $\text{FeCl}_3$ . Glycerol, glyceric acid, mannitol and HCHO in the presence of this soln. do not attack  $\text{PhNO}_2$ , while  $\text{CO}(\text{CH}_2\text{OH})_2$ , fructose and maltose immediately reduce it to  $\text{PhNH}_2$ . The foregoing expts. show that it is the configuration  $\text{RC}:\text{CH}_2\text{OH}$  or  $\text{RC}(\text{OH})\text{:CHOH}$  which is re-

sponsible for this peculiar reducing power, and it has been found that there is an extraordinarily large number of aromatic substances which behave like the sugars towards alkali nitrites, viz., those compds. found widely distributed in the vegetable kingdom which contain 2 or more HO groups in the  $C_6H_4$  ring, like pyrocatechol, quinol, pyrogallol, gallic acid, also phloroglucinol, quercetin, and the anthranols (chrysarobin), etc. All these, from dextrose to chrysarobin, are autooxidizable in alk. soln., forming active O and therefore having a strong oxidizing action, but in the presence of minute amts. of Fe in a masked form they at the same time reduce alkali nitrites; this reduction does not take place in the absence of O, except in the case of sugars which supply the necessary O from their own mols. Thus, if a soda soln. of 1,8-dihydroxyanthranol containing a few drops of  $FeCl_3$  is distd. with  $NaNO_2$  in a flask provided with an open tube reaching to the bottom of the liquid and through which air enters, NO soon begins to pass over with the distillate which gives the usual reactions for  $HNO_2$ , but contains no  $NH_3$ ; if, instead of air, N free from O is passed into the boiling soln., the evolution of NO soon ceases but if O is now substituted for the N the formation of NO again begins; this alternating process can be repeated many times. With dextrose in soda the admission of O is not necessary for the formation of NO. Nor is there any evolution of NO in the absence of Fe; in the case of 1,8-dihydroxyanthranol and other substances which form Fe complexes the addition of a little  $Fe(OH)_3$  is sufficient to start the evolution of NO, but with compds. like phloroglucinol the Fe must be added in the form of some such complex as  $K_4Fe(CN)_6$  or  $K_3Fe(CN)_6$ . Mn or Cu cannot be substituted for Fe. As to the role of the O in these reductions B. offers the explanation that the autooxidizable substances contain easily removed H atoms which under ordinary conditions are oxidized away by the coordinately bound  $O_2$  mol. while in the simultaneous presence of alkali nitrite and masked Fe it is probably a loose combination of the latter 2 which reacts with the labile H atoms. The part played by the masked Fe is not yet clear. It has been found, however, that these Fe complexes can exercise an oxidizing action on peroxides, with reduction and evolution of O. Thus, the deep violet-red (a)-Fe'' soln. in soda is decolorized by warming with  $H_2O_2$ , and after acidifying with dil. HCl and adding  $K_3Fe(CN)_6$  forms no Prussian blue, whereas the original soln. gives Prussian blue abundantly. (a)-Fe' solns. are colorless but are immediately colored intensely by the air. The possibility of a catalase action of the masked Fe atom in the above reductions of nitrites is not excluded. Possibly the autooxidizable phenols are plant hormones which play an important part in respiration.

C. A. ROUILLER.

**Direct transformation of nitriles into esters.** PAUL PFEIFFER. *Ber.* 51, 805 (1918).—With reference to the paper of Spiegel and Szydowski (*C. A.* 12, 2558), P. points out that he and Matton had already described the direct esterification of nitriles (*C. A.* 5, 2834).

C. A. ROUILLER.

**Synthesis of N-methyltetrahydropyridinecarboxylic acids. I. A new method of formation of arecaine and of arecoline.** Clearing up of the constitution of guvacine and of arecaine. KURT HESS and FRIEDRICH LEIBBRANDT. Univ. Freiburg i.B. *Ber.* 51, 806-20(1918); cf. *C. A.* 11, 2801; Jahn, *Arch. Pharm.* 229, 669(1891).—Nipecotinic acid, from nicotinic acid, Pd and  $H_2$ , was isolated as its *acetate*,  $C_8H_{11}O_5N$ . AcOH, needles from AcOH, m. 289-90° (decompn.), which does not decomp. as easily as the HCl salt in  $H_2O$ ; with  $HCHO \cdot HCO_2H$  it was converted into N-methylhexahydronicotinic acid (a), whose *methyl ester hydrochloride*, needles from  $MeOH \cdot AcOEt$ , m. 193° (decompn.); Me ester methiodide, prismatic, often striated plates from alc., m. 192° (Willstätter, *Ber.* 30, 730(1897), gives 155-6°); chloromethylate Au salt, m. 123° (W., 111-2°). *Ethyl ester* of (a), obtained in 10-2 g. yield by passing HCl for 24 hrs. into the methylation product of 25 g. hexahydronicotinic acid in 150 cc. boiling

alc.,  $b_{24-1}$  101-2°, strongly refractive basic oil producing coughing, hydrolyzed by boiling 4 hrs. with 25 parts *N* HCl, the hydrolyzed soln. yielding with  $\text{Cu}(\text{OH})_2$  a greenish copper salt,  $\text{C}_{14}\text{H}_{24}\text{O}_4\text{N}_2\text{Cu}$ . When 6.5 g. of the Me ester of (a) in 30 cc. MeOH is boiled 2 hrs. with 6.5 g. Br in 20 cc. MeOH, then 0.5 hr. with 1.8 g. Na in 25 cc. MeOH, filtered from the NaBr and esterified, it gives 3-3.5 g. Me *N*-methyl- $\Delta^2$ -tetrahydronicotinate (arecoline),  $b_{17}$  94°, hydrolyzed by boiling 3 hrs. with 50 parts *N* HCl to the acid (arecaine), whose ruby-red Au salt m. 196° (J., 197-8°). In the above bromination HBr is partially split off even without addition of NaOMe with formation of arecoline and *arecaine hydrobromides*; the latter can be isolated by evapg. the bromination reaction mixt. *in vacuo* to a sirup, letting stand *in vacuo* over  $\text{P}_2\text{O}_5$ , treating the partly crystd. mixt. with  $\text{Me}_2\text{CO}$ , filtering and adding  $\text{C}_6\text{H}_6$  to the concd. alc. son. of the crystals; it seps. in needles, m. 197° (decompn.). Methyl *N*-methyl-hexahydronicotinate,  $b_{21}$  92-5°, was obtained in 1 g. yield by methylating 4 g. pipercolinic acid acetate in the usual way, evapg. the  $\text{Et}_2\text{O}$  soln. of the reaction product, dissolving in  $\text{CHCl}_3$ , treating with somewhat more than the calcd. amt. of  $\text{PCl}_5$ , decanting the soln. from the resulting tar, treating it with MeOH, evapg. *in vacuo*, decompg. with soda and extg. with  $\text{Et}_2\text{O}$ . Ethyl ester hydrochloride, obtained by passing HCl gas over the ester, table-like crystals, m. 204° (decompn.). From 18 g. of the Et ester in 50 cc. alc. boiled with 16.8 g. Br in 50 cc. alc. and then with 5 g. Na in 100 cc. alc. and esterified with HCl in boiling alc. is obtained 12-3 g. of ethyl *N*-methyl- $\Delta^2$ -tetrahydronicotinate, refractive, strongly basic oil of somewhat sweetish, pleasant odor,  $b_{17}$  96°. Methyl ester, obtained in 1.7-2.0 g. yield from 3 g. of the hexahydro Et ester, possesses the same properties as the Et ester, reduces faintly alk.  $\text{KMnO}_4$  and Br  $\text{H}_2\text{O}$  in the cold, does not react with dil.  $\text{HNO}_3$ . Free acid obtained in 7-7.5 g. yield by shaking 8 g. of the Et ester with 8 g.  $\text{Ba}(\text{OH})_2$  in 80 cc.  $\text{H}_2\text{O}$  48 hrs. at 16°, crystals with 0.5  $\text{H}_2\text{O}$  from alc.- $\text{Et}_2\text{O}$ , sublimes somewhat at 110° and still more at 140°, m. 213-4°, sol. in 2 parts warm alc., forms a tasteless, neutral aq. soln., gives no color with  $\text{FeCl}_3$ ; hydrochloride, m. 210°; chloroplatinate, prisms from  $\text{H}_2\text{O}$ , m. 220° (decompn.); chloroaurate, short prisms, m. 200°. The acid and its derivs. resemble so closely the description given by Jahn of his arecaine that the 2 substances were believed to be identical until the latter was prepd. from the natural guvacine, when some errors in J.'s description were discovered. Three g. Merck's guvacine, which became only slightly yellow when heated to 270° and showed no tendency to melt (J.'s product darkened 265° and m. 271° (decompn.)), heated in 10 cc.  $\text{H}_2\text{O}$  with 1.8 g. 40%  $\text{HCHO}$  and 2.4 g.  $\text{HCO}_2\text{H}$  8 hrs. at 155-60°, gave 2.5 g. arecaine, m. 231° (decompn.) (J., 213-4°), seps. from 50% alc. with 1  $\text{H}_2\text{O}$ ; hydrochloride, seps. from abs. alc. in well defined crystals, m. 250° (decompn.); chloroplatinate, octahedrons, m. 220° (decompn.); chloroaurate, short prisms, m. 200° (foaming). From 2.6 g. of the HCl salt esterified with HCl and  $\text{EtOH}$  is obtained 2.3 g. of guvacine ethyl ester, strongly alkaline oil of faintly basic, not unpleasant odor,  $b_{17}$  116°, at once decolorizes alk.  $\text{KMnO}_4$  and Br  $\text{H}_2\text{O}$ , gives with more Br an oily insol. substance, probably the dibromide. With colloidal Pt and H, guvacine gives isonipecotinic acid. Guvacine and arecaine are therefore tetrahydro- and *N*-methyltetra- $\gamma$ -picolinic acids, resp., the position of the double bond still being undetd., but from analogy with arecaine, H. and L. consider the  $\Delta^2$ -structure,  $\text{CH}_2\text{CH}_2\text{NHCH}_2\text{CH}(\text{CO}_2\text{H})$ , most probable.

C. A. R.

**Anthocyanins: color-variation in anthocyanins.** KEITA SHIBATA, YUJI SHIBATA AND ITIZO KASIWAGI. *J. Am. Chem. Soc.* 41, 208-20(1919).—Former investigators have invariably used metallic Zn or Mg and excess of inorganic acid to reduce the yellow plant pigments of the flavonol series and obtained red anthocyanin pigments, the oxonium salts of Willstätter, but S., S. and K. have used organic acids. With mono-

basic acids they obtained, for the most part, deep green to bluish green pigments, depending on the reagent used, and have been able to isolate some of the pigments. Myricetin (I) with glacial AcOH and Mg gives compds. of the compn.  $C_{14}H_{11}O_8MgOAc \cdot nMg(OAc)_2$  ( $n = 2$  or  $4$ ). They represent the reaction as consisting in the formation, by reduction, of a phenopyrylium compd. (II) which, by loss of AcOH, yields the organo-metallic compd. (III) and this adds 2 or 4 mols. of  $Mg(OAc)_2$  according to Werner's coördination theory. Similarly myricitrin gives a deep blue product coördinated with  $4Mg(OAc)_2$ . These blue or green pigments are sol. in  $H_2O$  and alc. with the same color and form neutral solns., but with dil. acids the color changes to red with formation of the oxonium salt. Even with inorganic acids under certain conditions green or blue pigments are formed, myricetin with alc. HCl forming a deep green pigment (III, with  $MgCl_2$  instead of  $MgOAc$ ); in this case  $MgCl_2$  does not add coördinately. On the basis of their work, S., S. and K. conclude that organo-metallic or complex compds. of reduced flavonol glucosides are the most important factor in the production of flower colors; that the "blue" anthocyanins are the complex compds. of reduced flavonol glucosides containing several HO groups of the flavonol nucleus besides those of sugar mols. and the metal with which they are coördinated is probably Ca or Mg; and that the "violet," "violet-red" and "red pigments" are either the analogous metallic complex compds. of flavonol glucosides containing fewer auxochrome HO groups or are a mixt. of the blue pigments and their products of decompn. by excess of acids, *i. e.*, Willstätter's red oxonium salts. The theory proposed is confirmed by the fact that in alc. exts. of various flowers treated with salts of the alk. earths and heavy metals the color change is always bathochromatic, *e. g.*, from red or violet-red to beautiful blue or violet. The reversible color change of the exts. of some petals produced by temp. changes is interpreted as due to the formation and decompn. of the complex compds. Tables are given, showing the color of the pigment produced by reduction of myricetin in alc.,  $Me_2CO$  and  $Et_2O$  with Mg and formic, acetic, propionic, butyric, valeric, lactic, oxalic, citric, benzoic, *m*-nitrobenzoic, cinnamic, chloroacetic, trichloroacetic and camphoric acid, the colors produced by adding 1 drop of  $H_2O$  or dil. HCl to the reduced  $Me_2CO$  solns., the colors obtained by reduction of quercitin, quercitrin, rutin, kempferol, chrysin and toringin in alc., the colors obtained by reduction of myricetin with AcOH,  $ClCH_2CO_2H$  and  $CCl_3CO_2H$  and Zn in alc. and  $Et_2O$  and with Al-Hg in alc., and finally with Mg, Fe and Zn and HCl, HBr,  $HNO_3$ ,  $H_2SO_4$ ,  $H_3PO_4$  and  $H_2PO_3$ ; and finally the colors produced by adding salts of Ca, Sr, Ba, Mg, Zn, Al, Sn, Pb, Cr,  $NH_4$ , Mn, Fe, Ni, Co, Cu and Hg and AcOH, HCl, NaOH and  $K_2CO_3$  to alc. exts. of 24 flowers.

CHAS. A. ROUILLER.

2-Phenylcoumarins. ADOLF SONN. Univ. Königsberg i. Pr. *Ber.* 51, 821-7 (1918); cf. v. Meyer, *J. prakt. Chem.* 67, 342(1903).—The product of the action of HCl gas on  $PhC(:NH)CH_2CN$  (a) and *m*- $C_6H_4(OH)_2$  in glacial AcOH, purified through the Ac deriv. (silky needles from alc., m.  $121-2^\circ$ ), is identical with 7-hydroxy- $\beta$ -phenylcoumarin, tablets, m.  $245-6^\circ$  (v. Pechmann and Hanke, *Ber.* 34, 356(1901)), and not 7-hydroxyflavone, as believed by v. M. The reaction therefore does not follow the course he suggests; the first product is  $BzCH_2CN$  which then condenses with the  $C_6H_4$ -

(OH)<sub>2</sub>. Likewise with phloroglucinol (a) gives 5,7-dihydroxy- $\beta$ -phenylcoumarin, identical with the product obtained from  $\text{BzCH}_2\text{CO}_2\text{Et}$ , phloroglucinol and  $\text{ZnCl}_2$  (v. Kostanecki, *Ber.* 26, 2907(1893)).  $p\text{-MeOC}_6\text{H}_4\text{COCH}_2\text{CN}$  (b) (Bargellini and Forli-Forli, *C. A.* 5, 3805), prisms from alc., m.  $129\text{--}30^\circ$  (B. and F.-F.,  $128^\circ$ ), is obtained in 7.2 g. yield by gradually warming 10 g. KCN in 30 cc.  $\text{H}_2\text{O}$  and 30 cc. alc. with 8 g.  $\text{MeOC}_6\text{H}_4\text{COCH}_2\text{Cl}$  up to  $80^\circ$ , dilg. with considerable  $\text{H}_2\text{O}$ , filtering and acidifying; 4 g. of this and 3 g. anhydrous phloroglucinol suspended in 30 cc. AcOH and satd. with HCl give 4.7 g. crystals which, boiled 15 min. in 30 parts  $\text{H}_2\text{O}$ , yield 5,7-dihydroxy-4'-methoxy- $\beta$ -phenylcoumarin (c), flat prisms from 60% alc., sol. in concd.  $\text{H}_2\text{SO}_4$  with faint yellow color, gives only a faint and not characteristic color with  $\text{FeCl}_3$  in alc.; it is purified through the diacetate, flat prisms or elongated tables from alc., m.  $189\text{--}90^\circ$ .  $p\text{-Methoxybenzimidazoacetoniirile}$ ,  $\text{MeOC}_6\text{H}_4\text{C}(\text{NH})\text{CH}_2\text{CN}$ , obtained in 10.5 g. yield from 4.6 g. Na, 13 g.  $\text{MeOC}_6\text{H}_4\text{CN}$  and 8 g. MeCN in 50 cc.  $\text{Et}_2\text{O}$  warmed some hrs. on the  $\text{H}_2\text{O}$  bath and then decompd. with  $\text{H}_2\text{O}$ , prisms from AcOEt, m.  $119^\circ$ , yields (b) with dil. acids. When 10.5 g. (b) and 7.6 g. phloroglucinol suspended in  $\text{Et}_2\text{O}$  are satd. with HCl and allowed to stand overnight there are obtained 4.5 g. unchanged (b) and 3 g. 5,7-dihydroxy-4'-methoxy- $\beta$ -phenylcoumarin imino ether,  $(\text{HO})_2\text{-C}_6\text{H}_2\text{O.C}(\text{NH})\text{CH}:\text{CC}_6\text{H}_4\text{OMe}$ , crystals from 80% AcOH, decomp. above  $300^\circ$ , gives (c) on warming with  $\text{H}_2\text{O}$  or dil. acids.

CHAS. A. ROULLER.

**Isomerization of furaldiacetyl mono-oxime.** OTTO DIELS AND HERMANN ROEHLING. Univ. Kiel. *Ber.* 51, 828-36(1918).—Furaldiacetyl mono-oxime (a) is obtained in 50 g. yield from 50 g. furfural and 50 g.  $\text{AcC}(\text{:NOH})\text{Me}$  by D. and Sharkoff's modified method (*C. A.* 7, 2940); gently warmed with  $\text{Ac}_2\text{O}$  it yields almost quant. the acetate, prisms from MeOH, m.  $141^\circ$ , stable towards weak bases ( $\text{C}_6\text{H}_5\text{N}$ , carbonate), evolves a peculiar pleasant odor when warmed with bicarbonate in the presence of a little alc.; 1.6 g. gently warmed with 3 cc. of 33% KOH suddenly reacts violently with formation of a liquid of ethereal odor (which was not further investigated); on addition to the reaction mixt. of 13 cc. of  $\text{H}_2\text{O}$  and acidification there is obtained 0.8 g. of furfuracrylic acid. Unlike  $\text{PhCH}:\text{CHC}(\text{:NOH})\text{Ac}$ , which with concd. HCl gives an isoxazole deriv., when 5 g. finely powdered (a) is covered with 10 cc. concd. HCl it dissolves with evolution of heat and production of an intense olive-green color changing to brown and there soon seps. 4.3 g. of the cryst. salt,  $\text{C}_8\text{H}_7\text{O}_2\text{N.HCl}$ , leaflets from concd. HCl, turns brown about  $118^\circ$ , decomp.  $128\text{--}9^\circ$ , dissolves at once, with elimination of HCl, when rubbed with  $\text{H}_2\text{O}$  or with bicarbonate, gives a deep blue-red color with  $\text{FeCl}_3$  in alc. The free base (b), obtained by alternately bringing together small portions of the above salt and a few drops of bicarbonate soln., avoiding a great excess of alkali at any time and leaving the mixt. slightly acid at the end, is a greenish yellow powder sepg. from a little MeOH in needles, m.  $145^\circ$ , instantly dissolved by concd. HCl with characteristic olive-green color, sol. with orange-yellow color in dil. alkalies, carbonates and  $\text{NH}_4\text{OH}$ , instantly reduces Fehling soln. and  $\text{NH}_3\text{-AgNO}_3$ , gives in alc. with  $\text{FeCl}_3$  a deep violet-red color which disappears after a few moments, but is brought out again by more  $\text{FeCl}_3$ ; with excess of  $\text{FeCl}_3$  is obtained a deep  $\text{KMnO}_4$ -red color changing to light brown on long standing; with  $\text{PhN}_2\text{Cl}$  it couples instantly to a deep red compound sepg. from  $\text{Me}_2\text{CO}$  in thick hexagonal prisms; with  $\text{NH}_2\text{CONHNH}_2$  it gives a compound m.  $228\text{--}9^\circ$ ; with  $\text{ClCO}_2\text{Me}$  in  $N$  NaOH it yields the carbomethoxy derivative,  $\text{C}_{11}\text{H}_{11}\text{O}_4\text{N}$ , needles from  $\text{C}_6\text{H}_6$ , m.  $128\text{--}9^\circ$ , slowly sol. in dil. alkalies with yellow color;  $p\text{-nitrophenylhydrazones}$ , brown-red needles from MeOH, decomp.  $136\text{--}7^\circ$ . When 4.6 g. (b) is covered with 10 cc. of 50% aq.  $\text{NH}_2\text{Me}$  and allowed to stand there is pptd. about 1 g. of a substance sepg. from MeOH in thick  $\text{K}_2\text{CrO}_4$ -red rhombohedrons, m.  $183^\circ$ , while on still longer standing there seps. a compound  $\text{C}_{10}\text{H}_{12}\text{O}_2\text{N}_2$ , light yellow needles

from MeOH, m. 175°. D. and R. believe that the first step in the action of HCl on (a) consists in the opening of the furan ring and addition of H<sub>2</sub>O, with formation of HOCH:CHCH:C(OH)CH:CHC(:NOH)Ac, and that this, by loss of H<sub>2</sub>O, yields (b) which has the structure (I) or (II) (in soln. probably both forms exist simultaneously).

This structure is confirmed by the fact that (b) boiled in Me<sub>2</sub>CO with dil. H<sub>2</sub>SO<sub>4</sub> or heated in MeI at 100° is converted into the isomeric  $\alpha$ -furyl- $\gamma$ -acetyl- $\alpha,\beta$ -dihydroisoxazole (III), also obtained directly by boiling (a) in at least 50 parts H<sub>2</sub>O for 1 hr.; (III) seps. from MeOH in soft needles, m. 103-4°, indifferent towards CH<sub>2</sub>N<sub>2</sub>. C. A. ROUILLER.

The course of the reaction between diacetyl mono-oxime and aldehydes in the presence of ammonia: formation of dihydroxy[dihydroglyoxalines]. OTTO DIELS. Univ. Kiel. *Ber.* 51, 965-76(1918).—AcC(:NOH)Me (a) in the presence of NH<sub>3</sub> reacts with aldehydes with the greatest ease but the products are of a different type from those obtained in the presence of concd. HCl (*C. A.* 9, 2250) or concd. KOH (*C. A.* 7, 2940), being trialkyldihydroxy[dihydroglyoxalines] (I), probably formed by interaction of the (a), aldehyde and NH<sub>3</sub> with elimination of 2 mols. of H<sub>2</sub>O and production of the intermediate compd. (II), which then adds H<sub>2</sub>O to give (I). Thus, when 150 g. (a), 150 g. BzH, 120 g. of 25% NH<sub>4</sub>OH and 150 cc. alc. are brought together the temp. first falls and a clear brown soln. results; the temp. then rises and is kept at about 65°; the reaction is soon complete and on cooling and rubbing crystn. soon begins; after standing 20 hrs. there is obtained 280 g. of the compound C<sub>11</sub>H<sub>14</sub>O<sub>2</sub>N<sub>2</sub> (I, R = Ph), m. 120-1° (decomp.), becomes superficially yellow in bright light, sol. in cold. dil. NaOH and in hot soda, more concd. NaOH pptg. the Na salt as a very finely cryst. mass; it is also instantly sol. in dil. H<sub>2</sub>SO<sub>4</sub>, the cryst. sulfate soon sepg.; the nitrate seps. in prisms; heated above its m. p. it loses H<sub>2</sub>O and resolidifies, owing to the formation of the compound (II), m. 180°. When 75 g. (I) in 1800 cc. dil. H<sub>2</sub>SO<sub>4</sub> are treated with 280 g. K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> in 1500 cc. hot H<sub>2</sub>O and distd. there first passes over an oil with the odor of o-HOC<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>Me and crystals soon appear; the receiver is changed and about 750 cc. more of liquid are distd. over and on cooling 22 g. BzOH are obtained in the distg. flask and from the 2nd distillate. The first distillate is made alk., extd. with Et<sub>2</sub>O, dried with MgSO<sub>4</sub>, and fractionally distd.; it yields a little AcOH and 8-10 g. 5-methyl-3-phenyl-1,2,4-oxdiazole (Tiemann and Krüger, *Ber.* 17, 1696(1884)), b<sub>763</sub> 252-3°, m. 41°. From 50 g. (a), 50 g. furfural, 40 g. of 25% NH<sub>4</sub>OH and 50 cc. of 95% alc. is obtained 42 g. (in H<sub>2</sub>O without alc. the yield from 25 g. each of (a) and furfural and 20 g. NH<sub>4</sub>OH is 35 g.) of the compound C<sub>9</sub>H<sub>12</sub>O<sub>2</sub>N<sub>2</sub>, brownish leaves from H<sub>2</sub>O, sinters 105°, m. 112-3° (foaming) solidifies and m. again 170-1°, sol. in cold dil. HCl, the hydrochloride sepg. from the soln. in prisms; the compd. is sol. in concd. H<sub>2</sub>SO<sub>4</sub> with faint amethyst color changing to an emerald-green on addition of a very little HNO<sub>3</sub>; it is also sol. in cold dil. alkalies and 25% NH<sub>4</sub>OH and becomes intensely yellow in bright light. Heated at its m. p. or crystd. from boiling Me<sub>2</sub>CO, it loses H<sub>2</sub>O and forms the compound C<sub>9</sub>H<sub>10</sub>O<sub>2</sub>N<sub>2</sub>, m. 170-1°, converted back into the original compd. in contact with H<sub>2</sub>O and forms the same salts as the latter on treatment with acids and alkalies. If the reaction between (a), furfural, and NH<sub>4</sub>OH in alc. is carried out at 0°, the product is hydrofurfuramide, m. 117° (30 g. from 50 g. (a)). The compound C<sub>13</sub>H<sub>16</sub>O<sub>2</sub>N<sub>2</sub>, obtained in 13 g. yield from 20 g. (a) and 26 g. PhCH:CHCHO, faintly yellowish prisms from MeOH, sinters 131°, m. 138-9°, easily sol. in dil. alkalies, gives the Na salt (needles) with more concd. NaOH, forms a difficultly sol. hydrochloride, sulfate (hexagonal tables), and nitrate, yields BzH with K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> in boiling dil. H<sub>2</sub>SO<sub>4</sub>.

(I) ( $R = Ph$ ) is reduced by Zn dust in boiling 50% AcOH to a compound  $C_{11}H_{14}N_2$ , needles from  $C_6H_6$ , m.  $242^\circ$ , has a very marked power of subliming, insol. in hot or cold alkalis, sol. in very dil. HCl at room temp., in 20% HCl only on warming, forms a cryst. hydrochloride, sulfate and nitrate. AcH and (a) do not give directly a compd. of type (I); from 150 g. (a), in 1200 cc.  $H_2O$  treated with 45 g. AcH- $NH_3$  is obtained 129 g. of a compound  $C_{10}H_{17}O_2N_2$ , corresponding to (I) + (a) -  $H_2O$ , crystals from MeOH, m.  $129-30^\circ$ , converted into (a) and (I) ( $R = Me$ ) under the most varied conditions; e. g., by dil. alkalis or acids, even in  $H_2O$ , or by treatment with  $PhNHNH_2$  in dil. AcOH. The compound (I,  $R = Me$ ), best obtained (in 17 g. yield, together with 8 g. (a)) by dissolving 25 g. of the preceding compd. in 120 cc. hot  $H_2O$ , quickly cooling to room temp., extg. twice with  $Et_2O$  and evapg. the aq. soln., crystals from  $Me_2CO$ , has an intensely bitter-sweet taste, m.  $80-1^\circ$ , evolves gas energetically when heated on Pt, then becomes viscous and finally deflagrates suddenly, loses 1 mol.  $H_2O$  on gentle heating, forming a compound m.  $134^\circ$ .

CHAS. A. ROUILLER.

**New derivatives of antipyrine containing selenium.** FRITZ VON KONEK AND OSKAR SCHLEIFER. Univ. Budapest. *Ber.* 51, 842-55(1918); cf. *Chem. Ztg.* 1913, 1036, 1168; *C. A.* 8, 2320; Ger. pat. 299,510.—To 2 mols. pure dry antipyrine (a) in 50 much abs., alc.-free  $CHCl_3$  that no crystals sep. on cooling below  $0^\circ$  is slowly added 1 mol.  $Se_2Cl_2$  in  $CCl_4$ , best in a  $CO_2$  atm.; a yellowish ppt. quickly changing to red at once begins to sep. and towards the end converts the  $CHCl_3$  soln. into a thick paste. After short standing this is quickly drained, spread on clay, dried *in vacuo* over paraffin, powdered, macerated 2-3 hrs. with  $H_2O$ , again dried *in vacuo*, dissolved in hot 96% alc. and treated with hot  $H_2O$  to incipient turbidity; on cooling *diantipyril diselenide* (b),  $(C_{11}H_{11}ON_2)_2Se_2$ , seps. in yellow needles (which are freed from the small amt. of accompanying monoselenide by shaking with a little  $CHCl_3$ ), m.  $215-6^\circ$ . Its salts with even the strongest acids are instantly decompd. by  $H_2O$ . Shaking in  $CHCl_3$  with Hg serves only to purify it by removing traces of adherent metallic Se; no addition product similar to that obtained with the S analog is formed. Repeated crystn. from boiling  $C_6H_6$  or treatment with concd. HCl results in the sepn. of 1 atom of Se, whence it is concluded that, as is also generally accepted for  $Se_2Cl_2$ , (b) has the asym. structure  $R_2Se:Se$ . *Diantipyril monoselenide* (c) from (b) treated with HCl as long as Se seps., pearly iridescent scales from  $C_6H_6$ , m.  $240^\circ$  (decompn.), probably identical with the product obtained by the patented process ((a) treated with Se or  $SeO_2$  and concd.  $H_2SO_4$ ); its salts are immediately hydrolyzed in  $H_2O$ . HCl in  $CHCl_3$  yields the *dihydrochloride* as a light yellow amorphous ppt. assuming a reddish shade in the desiccator. *Mercuric chloride compound*, needles from alc. *Diantipyril selenium dichloride*,  $(C_{11}H_{11}ON_2)_2SeCl_2$ , from (a) and  $SeCl_4$  in  $CHCl_3$ , pearly scales from  $C_6H_6$ , m.  $225^\circ$ ; boiled with HCl (1:3) or with KOH, it gives (c); side reactions also take place, a small amt. of a substance free from Se but rich in Cl, m.  $85-7^\circ$ , being isolated. Neither  $TeCl_2$  nor  $TeCl_4$  could be made to react with (a). In the combustion of Se compds. good results were obtained by filling half of the long combustion tubes with  $PbCrO_4$ , half with  $CuO$  and having a 12-5 cm. layer of  $PbO_2$  at  $180-200^\circ$  at the front end of the tube. For detg. the Se good results were obtained by heating 0.2-0.3 g. substance with 10-2 cc.  $H_2SO_4$  until the soln. assumes a brownish green color or a chocolate-brown emulsion begins to appear (before the appearance of  $H_2SO_4$  fumes), cooling, pouring into 200 cc.  $H_2O$ , satg. with  $SO_2$ , boiling, adding 100 cc. more  $H_2O$ , letting stand overnight, filtering on a weighed paper and washing with hot  $H_2O$  and alc. The objectionable

feature of the method is that neither the length nor temp. of the heating with  $\text{H}_2\text{SO}_4$  can be detd. with absolute certainty; too long heating leads to partial oxidation to  $\text{H}_2\text{SeO}_4$ , the subsequent reduction of which in the presence of excess of  $\text{H}_2\text{SO}_4$  presents difficulties. The Frerich method (decompn. with  $\text{HNO}_3$  in the presence of  $\text{AgNO}_3$  and titration of the resulting  $\text{Ag}_2\text{SeO}_3$  with  $\text{NH}_4\text{CNS}$ ) also gave good results. The other methods tried (evapn. with  $\text{HNO}_3$ , oxidation with  $\text{HNO}_3\text{-KClO}_4$  or  $\text{Na}_2\text{O}_2$  and combustion in the calorimetric bomb with O under pressure) were not satisfactory.

CHAS. A. ROUILLER.

Some new derivatives of *p*-coumaric and vanillic acid. FRITZ VON KONEK AND EUGEN PACSU. Univ. Budapest. *Ber.* 51, 855-65(1918); cf. *Chem. Ztg.* 1914, 1195.—*p*- $\text{HOC}_6\text{H}_4\text{CH:CHCO}_2\text{H}$ , needles, m.  $206^\circ$  (decompn.), is obtained in 28 g. yield by heating an intimate mixt. of 40 g. *p*- $\text{HOC}_6\text{H}_4\text{CHO}$  and 64 g. anhydrous  $\text{NaOAc}$  with 100 g.  $\text{Ac}_2\text{O}$  8 hrs. at  $140\text{--}50^\circ$ , cooling to  $100^\circ$ , adding 1 l. boiling  $\text{H}_2\text{O}$ , filtering, washing well with  $\text{H}_2\text{O}$ , boiling a short time with 1.5 l. dil.  $\text{NaOH}$ , pptg. with excess of dil.  $\text{HCl}$ , boiling with 2-2.5 l.  $\text{H}_2\text{O}$ , filtering, satg. with  $\text{CaCO}_3$ , decolorizing with charcoal, filtering, pptg. with  $\text{HCl}$  and crystg. twice more from much  $\text{H}_2\text{O}$ . Me ester, obtained in 80% yield from the acid in  $\text{MeOH}$  satd. with  $\text{HCl}$  and allowed to stand 12 hrs., refractive, table-like crystals from alc., m.  $136\text{--}7^\circ$ , long needles from petr. ether; 2 g. of the ester with 0.5 g.  $\text{NaOH}$  in 50 cc.  $\text{H}_2\text{O}$  shaken 0.5 hr. with 2.2 g. *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{COCl}$  in 50 cc.  $\text{Et}_2\text{O}$  yields 3.3 g. *methyl-p-nitrobenzoyl-p-coumarate*,  $\text{O}_2\text{NC}_6\text{H}_4\text{CO}_2\text{C}_6\text{H}_4\text{CH:CHCO}_2\text{Me}$ , silky microneedles from  $\text{Ac}_2\text{O}$ , m.  $203^\circ$ , unchanged by short boiling with acids but quickly hydrolyzed by alkalis with formation of an intense red color. From 1 g. of the  $\text{NO}_2$  ester in 30 cc. alc. satd. with  $\text{HCl}$  treated slowly with the calcd. amt. of finely granulated  $\text{Sn}$  is obtained 0.7 g. of the *amino ester hydrochloride*, long needles from aq.  $\text{HCl}$ , becomes reddish  $205^\circ$ , decomp.  $215^\circ$ , sol. only in 1800 parts boiling  $\text{H}_2\text{O}$  containing  $\text{HCl}$ ; the *sulfate*, short needles, is still less sol. Free *amino ester*, obtained by dropping concd.  $\text{NH}_4\text{OH}$  into the boiling soln. of the salt and pptd. from alc. by  $\text{H}_2\text{O}$ , m.  $168\text{--}9^\circ$ . *p*- and *o*- $\text{O}_2\text{NC}_6\text{H}_4\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$  are obtained in 19.3 and 8.8 g. yield, resp., by warming 30 g.  $\text{PhCH}_2\text{CH}_2\text{CO}_2\text{H}$  with 300 g.  $\text{HNO}_3$  (d. 1.5) and 30 g. fuming  $\text{HNO}_3$  to  $85^\circ$ , pouring the purple soln. into 2 l. ice  $\text{H}_2\text{O}$ , filtering after 2 hrs., washing until the wash  $\text{H}_2\text{O}$  is free from acid, dissolving in 1.5 l. boiling  $\text{H}_2\text{O}$  and cooling to  $65^\circ$ , whereupon the *p*-acid seps. almost completely; the soln. is rapidly filtered and on further cooling the *o*-acid begins to sep. *p*-Nitrohydrocinnamyl chloride, from the acid and  $\text{SOCl}_2$  heated 1.5 hrs. on the  $\text{H}_2\text{O}$  bath, m.  $34\text{--}5^\circ$ , b<sub>16</sub>  $189\text{--}92^\circ$ . *Methyl p-nitrocinnamyl-p-coumarate*, needles from alc., m.  $131\text{--}2^\circ$ , unchanged by short boiling with acids, hydrolyzed by alkalis. *p*-Amino ester hydrochloride, obtained in 0.5 g. yield from 1 g. of the  $\text{NO}_2$  ester, decomp. about  $250^\circ$ , softening and reddening at a much lower temp., sol. in about 600 parts boiling  $\text{H}_2\text{O}$  containing  $\text{HCl}$ . *Sulfate*, microneedles. Free *amino ester*, long needles from alc., m.  $153\text{--}4^\circ$ . 5-Nitrovanillic acid, obtained in 62% yield from vanillin by Vogl's method (*Monatsh.* 20, 391), when heated 1 hr. on the  $\text{H}_2\text{O}$  bath with 5 parts  $\text{SOCl}_2$  gives the *chloride*, yellow, m.  $93\text{--}4^\circ$ ; short warming with  $\text{MeOH}$  converts it into the *methyl ester (methyl 3-methoxy-4-hydroxy-5-nitrobenzoate)*, light yellow needles from alc., m.  $148\text{--}9^\circ$ . This cannot be benzoylated by the usual methods (heating with  $\text{BzCl}$  or by the Schotten-Baumann process) but when 4.2 g. in 20 g.  $\text{C}_6\text{H}_5\text{N}$  is gently warmed 2 hrs. with 2.6 g.  $\text{BzCl}$  and allowed to stand 12 hrs. there is obtained 4.2 g. of *methyl 3-methoxy-4-benzoyloxy-5-nitrobenzoate*, light yellow-brown needles from alc., m.  $124\text{--}5^\circ$ , gives  $\text{BzOH}$  on long heating with acids, decompd. in hot alc. by  $\text{NaOH}$  with formation of an intense red color and production of the characteristic odor of  $\text{BzOEt}$ ; 1 g. reduced as above gives 0.5 g. of the *amino ester*, needles from alc., m.  $188\text{--}90^\circ$ ; *hydrochloride*, needles from aq.  $\text{HCl}$ , reddens  $200^\circ$ , decomp.  $236\text{--}40^\circ$ . *Sulfate*, short microneedles. The above  $\text{NH}_2$  ester hydrochlorides

have no action on the uninjured epidermis and do not show the specific anesthetic action of cocaine on the tongue.

CHAS. A. ROUILLER.

**Synthesis of some new naphthylpyrazolones.** FRITZ VON KONEK AND RICHARD MITTERHAUSER. Univ. Budapest. *Ber.* 51, 865-71 (1918); cf. *Chem. Ztg.* 1914, 1195.—*1-β-Naphthyl-3-methyl-4-benzyl-5-pyrazolone*,  $C_{16}H_{11}N.N:CHMe.CH(CH_2Ph)CO$ , faintly

pink needles from alc., m.  $153^\circ$ , is prepd. by stirring together 22 g.  $AcCH(CH_2Ph)CO_2Et$ , and 16 g.  $C_{10}H_7NHNH_2$ , whereby the temp. rises to  $35^\circ$ , and after 15 min. heating to  $90^\circ$ , then, after the vigorous foaming has ceased, to  $130-5^\circ$ ; after 0.5 hr. the product is poured into 100 cc. warm  $Et_2O$  and the ppt. is dissolved in excess of dil.  $NaOH$ , filtered and pptd. with 10%  $HNO_3$ ; it is insol. in acids; *picrate*, canary-yellow felted needles from very dil. soln. in alc. *4-Isopropyl analog*, yellowish needles from alc., m.  $160^\circ$ ; the  $NaOH$  soln., after exact neutralization of the excess of  $NaOH$  with  $HNO_3$ , gives colored caseous ppts. with  $Co$ ,  $Cu$  and  $Ag$  salts; *picrate*, yellow felted needles from alc. *1-α-Naphthyl-3-methyl-4-benzyl-5-pyrazolone*, obtained with much greater difficulty than the  $\beta$ -isomer and only when the purest reagents are employed (yield 50 g. from 28 g.  $\alpha-C_{10}H_7NHNH_2$  and 38 g.  $AcCH(CH_2Ph)CO_2Et$ ), faintly yellow rosetts from alc., m.  $168^\circ$ ; *picrate*, canary-yellow needles. *4-Isopropyl analog*, could not be obtained pure, even as a *picrate*. *1-β-Naphthyl-3-methyl-4-benzyl-5-benzoyloxypyrazole*, from 3 g. of the pyrazolone and 1.5 g.  $NaOH$  in 100 cc. warm  $H_2O$  treated with 4 g.  $BzCl$ , yellow needles from alc., m.  $138^\circ$ . No cryst.  $Bz$  derivs. of the  $\alpha-C_{10}H_7$  compds. could be obtained. The  $\alpha$ -naphthylpyrazolone (2 g.) in 50 cc. alc. treated with 3 g. powdered  $NaNO_2$  and concd.  $HCl$  yields the *dipyrazolone*,  $C_{22}H_{14}O_2N_4$ , crystals from alc., m.  $215^\circ$ . *1-β-Naphthyl-3-methyl-5-pyrazolidone*,  $C_{16}H_{11}N.NH.CHMe.CH_2CO$ ,

from 25 g.  $C_{10}H_7NHNH_2$  and 14 g. solid crotonic acid cautiously heated to  $135^\circ$ , crystals from alc., m.  $107^\circ$ , insol. in alkalis, sol. with difficulty but completely in hot concd.  $HCl$ , only partially oxidized by  $FeCl_3$  in alc. to the pyrazolone. *1-β-Naphthyl-4-benzyl-5-methyl-3-pyrazolone*, from 10 g.  $C_{10}H_7NHNHAc$ , 11 g.  $AcCH(CH_2Ph)CO_2Et$  and 7 g.  $PCl_5$ , yellow needles from xylene, m.  $208^\circ$ . *4,4'-Diphenylenebis[3-methyl-4-benzyl-5-pyrazolone]*, from  $(p-NH_2NHC_6H_4)_2$  and  $AcCH(CH_2Ph)CO_2Et$ , yellowish powder.

**A new group of cyclopropane derivatives. II. Action of some analogs of the phenacyl halides on 3-acylcoumarins.** OSKAR WIDMAN. Univ. Upsala. *Ber.* 51, 907-11 (1918);

(1. *C. A.* 12, 2567.—*3-Acetyl-3,4-anisacylidenecoumarin*,  $\begin{array}{c} C_6H_4.CH \\ | \\ O.CO.CAc \end{array} \rangle CHCO_2C_6H_4OMe$ ,

from  $p-MeOC_6H_4COCH_2Cl$ , 3-acetylcoumarin and  $NaOEt$ , long needles, m.  $163^\circ$ , gives no  $FeCl_3$  reaction and does not reduce  $KMnO_4$  in  $Me_2CO$ . The alc. mother liquors from the coumarin on evapn. yield *ethyl α-acetyl-α,β-anisacylidenecoumarinate*,  $HOC_6H_4-CH.CH(COC_6H_4OMe).CAcCO_2Et$ , long 4-sided, flat prisms with 1 mol. solvent from

$C_6H_4$ , m. about  $70^\circ$ , resolidifies and m. again around  $90-116^\circ$ , loses its  $C_6H_4$  after several hrs. at  $75^\circ$  and then m.  $119-20^\circ$ , gives no  $FeCl_3$  reaction, gives a hard oil with boiling  $Ac_2O$ . *3-Benzoyl-3,4-anisacylidenecoumarin*, long prisms from  $AcOH$ , m.  $190^\circ$ . *Ethyl 3,4-anisacylidenecoumarin-3-carboxylate (a)*, prepd. in the usual way, prisms from alc., m.  $165-6^\circ$ , does not reduce  $KMnO_4$ . *β-Hydroxyphenyl-β-hydroxy-α-anisacylthane-α,α-dicarboxylic acid*,  $HOC_6H_4CH(OH)C(CO_2H)_2CH_2COC_6H_4OMe$ , obtained by shaking and gently warming the above ester with 4%  $NaOH$ , short prisms from  $AcOH$ , m.  $119-20^\circ$  (decompn.); the filtrate from this yields after some days *anisacylmalic acid*, needles, m.  $162^\circ$  (decompn.), gives no color with  $FeCl_3$ , also obtained from  $Na$  in alc.,  $CH_2(CO_2Et)_2$  and  $p-ClCH_2COC_6H_4OMe$  and long shaking of the resulting oil with 6%

KOH. Diethyl  $\alpha, \beta$ -anisacylidenesalicylidene-malonate,  $\text{HO} \cdot \text{C}_6\text{H}_4 \cdot \text{CH}(\text{CO} \cdot \text{C}_6\text{H}_4 \cdot \text{OMe}) \cdot \text{C}$ -

$(\text{CO}_2\text{Et})_2$ , crystals from MeOH, m.  $99-100^\circ$ , seps. from the alc. mother liquors obtained in the prepn. of (a); it does not reduce  $\text{KMnO}_4$  and gives no color with  $\text{FeCl}_3$ . 3-Acetyl-3,4-*o*-methoxyphenacylidene-coumarin, from 3-acetylcoumarin and *o*- $\text{ClCH}_2\text{CO} \cdot \text{C}_6\text{H}_4 \cdot \text{OMe}$ , prisms from alc., m.  $144-5^\circ$ , does not reduce  $\text{KMnO}_4$ . Ethyl 3,4-*m*-nitrophenacylidene-coumarin-3-carboxylate, from *m*- $\text{O}_2\text{NC}_6\text{H}_4\text{COCH}_2\text{Br}$  and Et coumarin-3-carboxylate, prisms from AcOH, m.  $162-3^\circ$ , does not decolorize  $\text{KMnO}_4$ ; the mother liquors yield diethyl  $\alpha, \beta$ -*m*-nitrophenacylidenesalicylidene-malonate, crystals from alc., m.  $132-3^\circ$ . 3-Acetyl-3,4-naphthacylidene-coumarin, from 6.5 g.  $\alpha\text{-C}_{10}\text{H}_7\text{COCH}_2\text{Cl}$  (b<sub>18</sub>  $204-5^\circ$ , prepd. from  $\text{ClCH}_2\text{COCl}$  and  $\text{C}_{10}\text{H}_8$  in the presence of  $\text{AlCl}_3$  in  $\text{CS}_2$ ), 6 g. 3-acetylcoumarin and 0.734 g. Na in alc., prisms from AcOH, m.  $133-4^\circ$ , does not reduce  $\text{KMnO}_4$ ; yield, 4.2 g. III. Range and mechanism of the reaction of formation. Behavior of 3-acetylcoumarin towards alkali. *Ibid* 1210-4.—As shown in the earlier

papers, in the reaction  $\text{RCOCH}_2\text{Cl} + \text{C}_6\text{H}_4 \cdot \text{CH} : \text{CR}' \cdot \text{CO} \cdot \text{O} = \begin{array}{c} \text{C}_6\text{H}_4 \cdot \text{CH} \\ | \\ \text{O} \cdot \text{CO} \cdot \text{CR}' \end{array} \rangle \text{CHCOR} \text{ (a)}$

+HCl, R may be Ph, *p*- and *o*- $\text{MeOC}_6\text{H}_4$ ,  $\text{O}_2\text{NC}_6\text{H}_4$  and  $\text{C}_{10}\text{H}_7$  and R' may be Ac, EtCO, Bz,  $\text{CO}_2\text{Et}$ ,  $\text{CO}_2\text{Me}$  and CN. It has now been found that the reaction does not take place if R is Me and R' is Ph or H, moreover, that the coumarin ring is essential and that there must be an acyl,  $\text{CO}_2\text{R}$  or CN group in position 3 (R' in the above formula); neither di-Et fumarate,  $[(\text{EtO}_2)\text{CC}]_2$ ,  $\text{PhCH} : \text{CAcCO}_2\text{Et}$ ,  $\text{PhCH} : \text{C}(\text{CO}_2\text{Et})_2$ , *p*- $\text{MeOC}_6\text{H}_4\text{CH} : \text{CAcCO}_2\text{Et}$ , *o*- $\text{EtOC}_6\text{H}_4\text{CH} : \text{CAcCO}_2\text{Et}$  nor Et coumarin-4-carboxylate condenses with phenacyl halides in the presence of Na alcoholates. It has also been found that trimethylacetyl- and 3-benzoylcoumarin react towards alkalies just like 3-acetylcoumarin, i. e., if the yellow alk. soln. is neutralized the color disappears and the clear soln. deposits the original coumarin very slowly in the cold, quickly on warming or adding a mineral acid, but if the alk. soln. is warmed the color disappears and acids at once ppt. an acid stronger than the original coumarin. W. believes that cold NaOH forms at first an *o*-quinoid salt,  $\text{O} : \text{C}_6\text{H}_4 : \text{CHCAc} : \text{C}(\text{ONa})\text{OH}$ , which on acidification gives the colorless,  $\text{H}_2\text{O}$ -sol.  $\alpha$ -acetylcoumarinic acid (I), which is spontaneously transformed into acetylcoumarin, slowly in the cold but rapidly on warming or in the presence of strong acids, whereas if the alk. soln. is heated there is a steric rearrangement into  $\alpha$ -acetylcoumaric acid (II), which, as a  $\beta$ -ketonic acid, easily loses  $\text{CO}_2$  but cannot be converted into an anhydride. In alc. a similar *o*-quinoid addition product,  $\text{O} : \text{C}_6\text{H}_4 : \text{CHCAc} : \text{C}(\text{ONa})\text{OEt}$ , is formed. These, with reactive halogen compds., like the phenacyl halides, form compds. of the type  $\text{O} : \text{C}_6\text{H}_4 : \text{CHAc}(\text{CH}_2\text{Bz})\text{CO}_2\text{R}$  (R = H or Et) which rearrange into the cyclopropane deriv.  $\text{HO} \cdot \text{C}_6\text{H}_4 \cdot \text{CH} \cdot \text{CHBz} \cdot \text{CAcCO}_2\text{R}$  and finally (a).

CHAS. A. ROUILLER.

Simplified preparation of triaryltin halides. ERICH KRAUSE. Techn. Hochschule, Berlin. *Ber.* 51, 912-4 (1918).—In attempting to prep. triaryltin bromides by direct bromination of Sn tetraaryls it was found that even under the mildest conditions of bromination, such as in suspensions in indifferent solvents with the calcd. amt. of Br at the lowest possible temp. at which any reaction at all takes place, the chief product was always the dibromide with only a little monobromide while almost half of the the original material remained unchanged. These difficulties can be overcome, how-

ever, by brominating in  $C_6H_5N$ , 90-5% yields of monohalides being obtained in this way. The sepn. of the diaryl dibromide formed in small amt. can be easily effected by taking advantage of the fact that the triaryl hydroxide, unlike the diaryl dihydroxide, is easily sol. in  $Et_2O$ . Thus, 85.4 g.  $SnPh_4$  is dissolved in 700 cc. hot  $C_6H_5N$ , quickly cooled in ice with stirring, treated with 32 g. Br in 150 g.  $C_6H_5N$  at  $-48^\circ$  (cooled by addition of solid  $CO_2$ ) in 6 portions in the course of 2.5 hrs., distd. up to  $175^\circ$  (bath temp.), then for a short time *in vacuo* to remove  $PhBr$ , dissolved in  $Et_2O$ , shaken with dil. HCl, filtered, shaken twice with 30% NaOH, filtered, converted into the halide by treatment with HCl, HBr or HI and crystd. from  $Et_2O$ .  $Ph_3SnCl$  seps. in partly octahedral, partly prismatic crystals, m.  $106^\circ$ ,  $b_{111}$   $240^\circ$ . *Triphenyltin bromide*, columns or octahedrons, m.  $120.5^\circ$ ,  $b_{111}$   $249^\circ$ . *Iodide*, 4-sided monoclinic prisms, m.  $121^\circ$ ,  $b_{111}$   $253^\circ$ .

CHAS. A. ROUILLER.

**Quinoneimide dyes. X. Absorption spectra of the simplest triphenylmethane dyes.** F. KEHRMANN AND M. SANDOZ. Univ. Lausanne. *Ber.* 51, 915-22 (1918); cf. *C. A.* 12, 2565.—A table is given showing the absorption in the visible spectrum and the color tone of the different colored series of salts of  $Ph_3COH$ ,  $p\text{-}H_2NC_6H_4CPh_2OH$ ,  $(p\text{-}H_2NC_6H_4)_2CPhOH$  and  $(p\text{-}H_2NC_6H_4)_3COH$  on the one hand and of their *N*-dimethyl derivs. on the other. The yellow, most highly acid salts of all the dyes studied show practically the same absorption as that of  $Ph_3COH$  in concd.  $H_2SO_4$ , a one-sided extinction of the visible violet. In the Me derivs., as the result of the weak auxochromic action of the Me groups, the left limit is shifted somewhat towards the longer wave lengths and lies generally in the region  $\lambda_{480-490\mu}$ . Therefore all these salts must have a similar constitution, and especially the same chromophore, as the yellow  $Ph_3COH$  salts. The *p*-quinoneimide grouping,  $R_3C:C_6H_4:NH_2X$ , characteristic of the deeply colored salts can no longer be present in these cases; the auxochromic influence of the  $NH_2$  groups is almost entirely destroyed by their neutralization by the acid, and the structure  $R_3C(HX):C_6H_4:(NH_2)X$  is provisionally suggested. The methylated dyes give an ideal picture of the differing optical effect of salt formation on the chromophore, on the one hand, and on the auxochrome on the other; triacid crystal violet, diacid malachite green and monoacid dimethylaminofuchsimonium have almost identical orange-red colors with only a very slight shifting of the max. towards longer wave lengths with increasing Me content. The auxochrome influence of  $Me_2N$  groups seems to be almost destroyed by salt formation but not the influence of the chromophore. Similarly diacid crystal violet and monoacid malachite green are green-blue and only monoacid crystal violet is blue-violet. In the series of non-methylated dyes there are some irregularities which can, however, without exception, be explained by the fact that dil. solns. of these dyes generally represent equilibria markedly conditioned by temp., concn. and acid content. Thus, when a dil. aq. soln. of pararufuchsin is treated with a little HCl there appears first a red with much more bluish tinge, which may be called red-violet, resulting from the formation of the diacid salt, corresponding optically to monoacid Döbner violet; this color, however, fades out almost completely in a few min. with formation of the colorless carbinol salt; on warming the almost colorless soln. it again becomes intensely red-violet and once more fades away on cooling. If the red soln. is quickly treated with relatively much acid the violet-red color appears first and then an orange-yellow with more acid, the latter due to the triacid salt corresponding to monoacid fuchsimonium chloride, but this color also quickly disappears. If the acid content, however, surpasses a certain limit, a more or less intense yellow color persists, owing to the formation of a certain amt. of the tetra-acid salt, corresponding to  $Ph_3COH$  salts. Therefore, before making any measurements, it was necessary to det. empirically under what conditions solns. could be obtained which did not markedly change in tone for a few min. at least and could be characterized as optic-

ally homogeneous as possible. Triacid parafuchsin, diacid Döbner violet and monoacid fuchsimonium are almost identically orange-yellow with the max. of the broad main band lying between 480 and 485  $\mu\mu$ ; the soln. of the first also showed the band with a max. at  $\lambda$  585  $\mu\mu$  characteristic of the diacid salt. Monoacid Döbner violet and diacid parafuchsin are subjectively almost identically KMnO<sub>4</sub>-violet; here again, however, the parafuchsin soln. contains a mixt., for it also shows the band  $\lambda$  547  $\mu\mu$  characteristic of the monoacid salt. Comparison of the methylated and non-methylated dyes shows that the substitution of the amino H atoms by Me groups has a bathochromic effect and that in Döbner violet as in malachite green the entrance of a 2nd *p*-NH<sub>2</sub> group has a distinct hypsochromic effect. XI. Absorption spectra of some amino derivatives of naphthophenazonium. *Ibid* 923-8.—A table similar to that in the preceding paper is given. The 6-NH<sub>2</sub> deriv., both as base and as salt, exists only in the *p*-quinoid position of equil. The imide base is lemon-yellow and forms orange-yellow monoacid and dark blood-red diacid salts. The 3-NH<sub>2</sub> deriv., orange-yellow as imide base, forms fuchsin-red monoacid and green-blue diacid salts, all three *p*-quinoid. There also exists a blue-violet triacid salt whose absorption probably corresponds to that of the thus far unknown diacid naphthophenazonium and which is probably *o*-quinoid. The 3,6-(NH<sub>2</sub>)<sub>2</sub> deriv. is orange-yellow as imide base and forms blue-violet monoacid salts with red fluorescence, orange-yellow diacid and dark blood-red triacid salts; the tetra-acid salts are lacking. The diacid salts, however, do not correspond to the monoacid salts of the 3-NH<sub>2</sub> deriv., but are identical in color with the 6-NH<sub>2</sub> monoacid salts. Similarly the triacid salts correspond to the diacid 6-NH<sub>2</sub> and not the diacid 3-NH<sub>2</sub> salts. Therefore, in passing from the violet monoacid to the diacid di-NH<sub>2</sub> salt, the 2nd equiv. of acid neutralizes the 3-NH<sub>2</sub> group and destroys its optical effect; the 3rd equiv. of acid adds to the azine N. Investigation of Meldola blue showed that it behaves normally, *i. e.*, like a *N*-dimethyl deriv. of the 3-amine. In the ultra-violet alc. solns. of the monoacid salts of the monoamines show almost identical extinctions; the spectrum is characterized by 2 bands lying close together,  $\lambda$  265 and 285  $\mu\mu$ , almost coinciding in 1 case (275  $\mu\mu$ ) and another band at about 330  $\mu\mu$  (320  $\mu\mu$  in the case of the diamine).

CHAS. A. ROULLER.

*N*- and *O*-Methyl ethers of ketoximes. The four isomeric methyl ethers of *p*-tolylphenyl ketoxime. LEOPOLD SEMPER AND LEO LICHTENSTADT. Landw. Hochschule, Berlin. *Ber.* 51, 928-42 (1918); cf. Alessandri, *C. A.* 9, 1045.—When an aq. alc. alk. soln. of Ph<sub>2</sub>C:NOH is treated with Me<sub>2</sub>SO<sub>4</sub> (MeI gives poor yields) the isomeric *N*- and *O*-ethers are obtained in about equal amts. They are sepd. by means of cold petr. ether, b. 30-50°, in which the *N*-ether is very difficultly sol. and further by passing HCl into an Et<sub>2</sub>O soln., whereby only the HCl salt of the *N*-ether is pptd. If the methylation is not complete there is also formed an addition product of the *N*-ether with Ph<sub>2</sub>C:NOH, which is likewise insol. in cold petr. ether and small amts. of which render the purification of the ether very difficult. The *N*-ether seps. from ligroin in long needles, m. 102-3°, hydrolyzed by short warming with dil. acids or alkalis, forms with various substances *addition compounds* which are strongly dissociated in soln.; among these were isolated the following: with 0.5 mol. water, m. 78-80°; *benzophenone oxime*, m. 108-9°; 0.5 mol. *quinol*, m. 186-6.5°; *phenyl isocyanate*, m. 141-2°. From that with Ph<sub>2</sub>C:NOH the components can be isolated pure by alternate treatment with dil. alkalis and acids. The *O*-ether seps. from petr. ether in crystals m. 60-1°, decompd. only on long boiling with concd. acids, concd. H<sub>2</sub>SO<sub>4</sub> giving a mixt. of BzNHPh, BzOH, PhNH<sub>2</sub> and BzOEt while fuming HCl yields Ph<sub>2</sub>CO and NH<sub>2</sub>OMe.HCl, exclusively; the ether forms no addition compds. By fractionation of the mixt. of the  $\alpha$ - and  $\beta$ -oximes of *p*-MeC<sub>6</sub>H<sub>4</sub>COPh from dil. alc. instead of AcOH-H<sub>2</sub>O, the 2 forms were isolated in pure state, and while the  $\alpha$ -oxime was found to m. 153-4°, as given by Hantzsch

(Ber. 23, 2326(1890)), the  $\beta$ -oxime m. 136.5–7.5° and not 115–6°. The 2 oximes were methylated and the *O*- and *N*-ether of each stereomer was sepd. as described above, but owing to the additive power of the *N*-ethers they were generally obtained in the forms of addition products with the corresponding oxime, the cold aq. alc. alk. solns. of which were acidified with dil.  $\text{H}_2\text{SO}_4$ , whereupon only the oxime sepd. while the *N*-ether was obtained by treating the soln. with alkali and extg. with  $\text{Et}_2\text{O}$ . The  $\alpha$ -oxime *N*-ether seps. in tablets m. 91–2°, the *O*-ether in needles, m. 70.5–2.0°.  $\beta$ -Oxime *N*-ether, long prisms, m. 113–4°; *O*-ether, oil,  $b_{18}$  184–5°. The *N*-ethers are quant. hydrolyzed by boiling dil.  $\text{HCl}$  to  $\text{MeC}_6\text{H}_4\text{COPh}$  and  $\text{MeNHOH.HCl}$  and on reduction give a compd. whose hydrochloride,  $\text{C}_{15}\text{H}_{18}\text{NCl}$ , m. 199–201°. The following  $\alpha$ -oxime *N*-ether addition products were isolated: with 0.5 mol. water, m. 66–7.5°; *p*-tolyl phenyl  $\alpha$ -ketoxime, m. 106–7°; *p*-tolyl phenyl  $\beta$ -ketoxime, m. 90–2°.  $\beta$ -Oxime *N*-ether addition products with: *p*-tolyl phenyl  $\beta$ -ketoxime, m. 81–2°;  $\alpha$ -ketoxime, m. 124–5°. The *O*-ethers are insol. in dil. acids and not decompd. on warming and form no addition products. C. A. R.

**Guvacine.** KARL FREUDENBERG. Univ. Kiel. Ber. 51, 976–82(1918); cf. Jahn, Arch. Pharm. 229, 669(1891).—A sample of Merck's guvacine (a), studied by F., showed no rotation in 10% aq. soln., gave a rust-red color with not too dil.  $\text{FeCl}_3$ , decompd. 285° (cor.) when rapidly heated (J., 271–2° (uncor.)), evolving vapors giving a strong pine splinter reaction; hydrochloride, decomp. 316°; chloroplatinate, decomp. 220–1°; chloroaurate, decomp. 197–9°. Contrary to J.'s statement, (a) can be esterified by using a sufficiently dil. soln. in  $\text{MeOH}$  (5 g. (a) in 100 cc.  $\text{MeOH}$  and 15 cc.  $\text{MeOH}$  satd. at 0° with  $\text{HCl}$ , boiled gently for 4 hrs.). The methyl ester hydrochloride, m. 121–2°, deliquesces in the air; chloroplatinate, silky, golden yellow leaflets, m. 211° (decompn.); free ester,  $b_{18}$  114°, solidifies 27°. When 4 g. of the ester in 5 cc.  $\text{MeOH}$  are allowed to stand 24 hrs. at 20° with 6 g.  $\text{MeI}$  in 5 cc.  $\text{MeOH}$ , then dild. with 30 cc.  $\text{EtOH}$ , 3 g. arecoline methiodide, m. 173–4°, crystals out; the mother liquor is concd. *in vacuo* and on treatment with alkali yields arecaidine,  $b_{18}$  104–12°; hydrochloride, decomp. 261°; chloroplatinate, decomp. 228–9°; chloroaurate, decomp. 198–9°. The above results show that (a) is identical with the tetrahydronicotinic acid,  $\text{CH}_2\text{NH.CH}_2\text{CH}_2\text{CH.CCO}_2\text{H}$ , obtained by Wohl and Losanitsch from imidodi-

propionacetal (C. A. 2, 839), and that J.'s arecaine is really arecaidine. *p*-Toluenesulfoguvacine, obtained in 4.3 g. yield from 2 g. (a) in 25 cc. of 2 *N*  $\text{NaOH}$  shaken 12 hrs. with 4.5 g. *p*- $\text{MeC}_6\text{H}_4\text{SO}_2\text{Cl}$ , plates from  $\text{C}_6\text{H}_6$ , m. 167–8°; 2 g. of this in 20 cc. of *N*  $\text{KOH}$  at –3° treated in the course of a few min. with 1.5 g. solid  $\text{KMnO}_4$ , then with 8–10 cc. of 40% aq.  $\text{NaHSO}_3$  and 25 cc. of 5 *N*  $\text{H}_2\text{SO}_4$ , gives 1.5 g. of *p*-toluenesulfodihydroxyimpecotinic acid, leaflets from  $\text{Me}_2\text{CO-H}_2\text{O}$ , m. 213–4°; 1 g. in 60 cc.  $\text{AcOH}$  and 3 cc.  $\text{H}_2\text{O}$  ozonized several hrs. at 18–20° gives 0.8 g. *N*-*p*-toluenesulfo- $\beta$ -propioiminoacetic acid,  $\text{HO}_2\text{CCH}_2\text{CH}_2\text{N}(\text{SO}_2\text{C}_6\text{H}_4\text{Me})\text{CH}_2\text{CO}_2\text{H}$ , prisms and plates from  $\text{H}_2\text{O}$ , m. 164°. The m. p. given above are cor. CHAS. A. ROUILLER.

**Guvacine methyl ester (guvacoline) and its natural occurrence.** KURT HESS. Univ. Freiburg i. B. Ber. 51, 1004–6(1918).—Crystals of a new prepn. from the betel nut supplied to H. by Merck yielded quant., on hydrolysis with  $\text{Ba}(\text{OH})_2$ , guvacine hydrobromide, needles, m. 280° (foaming), the natural product proving to be the  $\text{HBr}$  salt of the methyl ester, for which the name guvacoline is proposed. The hydrobromide, short prisms from  $\text{Me}_2\text{CO}$ , m. 144–5°, identical with the Merck product, was synthesized by boiling 2 g. guvacine 12 hrs. with 40 cc.  $\text{MeOH}$  satd. with  $\text{HCl}$ , evapg. *in vacuo* and rubbing with 25%  $\text{HBr}$ . CHAS. A. ROUILLER.

**Degradation of scopolone. III. Scopolone  $\rightarrow$  hydroscopolone  $\rightarrow$  tropan.** KURT HESS. Freiburg i. B. Ber. 51, 1007–15(1918); cf. C. A. 11, 964.—By a modification of the method earlier described (C. A. 10, 770), omitting the isolation of the

intermediate products, hyoscopoline (a) can be obtained with much greater ease: 10 g. scopoline (b) in 70 g. AcOH satd. at 0° with HBr is heated 6 hrs. at 125–30°, evapd. to dryness *in vacuo* at 40°, reduced with 24 g. Zn dust and 400 cc. of 20% H<sub>2</sub>SO<sub>4</sub> at 29–35°, heated 1 hr. on the H<sub>2</sub>O bath, filtered, neutralized with soda, evapd. to dryness *in vacuo* at 40°, extd. with abs. alc. in a Soxhlet, evapd., dissolved in 100 cc. H<sub>2</sub>O, made strongly alk. with solid NaOH and extd. 2–3 days with Et<sub>2</sub>O; yield, 9 g., m. 165°. When 1 g. (a) in 10 g. fuming HI is heated 5 hrs. at 195–205° with 4 g. PH<sub>4</sub>I and the combined products from 7 such operations are treated with 70 cc. H<sub>2</sub>O, decolorized with SO<sub>2</sub>, decanted from the red-brown insol. matter, concd. *in vacuo*, made alk., distd. with steam until the distillate is no longer alk. and the distillate is neutralized with N HCl (required, 14 cc., corresponding to a 25% yield) and evapd. *in vacuo* the residual sirup solidifies in a few days to needles, somewhat deliquescent in air of the HCl salt of tropin (I); chloroplatinate, orange needles, decomp. 229–30°; chloroaurate, prisms from H<sub>2</sub>O, m. 242–3° (decompn.); picrate, needles, m. 281° (decompn.). The alk. soln. remaining after removal of the (I) with steam yielded to Et<sub>2</sub>O 3.5–4.0 g. unchanged (a) out of the original 7 g. A product identical with (I) was obtained in 3.7 g. yield from 5 g. tropine, 5 g. PH<sub>4</sub>I and 25 g. fuming HI. These results establish that the structure of (a) is (II). The position of the two O atoms in (b) is not yet established; H. doubts the 1,2-ether structure proposed by Schmidt (C. A. 10, 1520), and believes the O bridge extends from C atom 2 to C atom 3, 4, 5, 6 or 7. When 8 g. hyoscopoline bromide-HBr is boiled 3.5 hrs. with 50 cc. concd. HCl it gives 5.6 g. of the chloride hydrochloride, C<sub>8</sub>H<sub>15</sub>O<sub>2</sub>NCl<sub>2</sub>, broad needles from alc., m. 289° (decompn.), converted quant. into (b) by treating with 25% NaOH and extg. with Et<sub>2</sub>O; attempts to oxidize it with CrO<sub>3</sub> in H<sub>2</sub>SO<sub>4</sub> gave only (b), while

Ag<sub>2</sub>O in H<sub>2</sub>O at 95° gave norscopoline. Nortropine with HI and PH<sub>4</sub>I gives nortropan (o. 8 g. from 1 g. nortropine). CHAS. A. ROUILLER.

Degradation of scopoline. ERNST SCHMIDT. Marburg. Ber. 51, 1281–3 (1918). —S. protests against the continued invasion of his field by Hess (preceding abstr.). CHAS. A. ROUILLER.

Reactions of tertiary amines and contribution to steric hindrance. Action of nitrous acid on methyl *p*-dimethylaminobenzoate and *p*-dimethylaminobenzaldehyde. FRANZ KLAUS AND OSKAR BAUDISCH. P. Beiersdorf & Co., Hamburg. Ber. 51, 1036–48 (1918); cf. C. A. 1, 730. —When 5 g. *p*-Me<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>Me in 40 cc. concd. HCl and 50 cc. H<sub>2</sub>O at –5° is slowly treated with 6 g. NaNO<sub>2</sub> in 12 cc. H<sub>2</sub>O and allowed to stand 0.5 hr., there is obtained 2 g. of a faintly yellow ppt. which, rubbed with 30 cc. of 1:2 HCl, filtered and crystd. twice from dil. alc. yields methyl *p*-methylnitrosaminobenzoate (a), MeN(NO)C<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>Me, needles, m. 115.5°, easily sol. in concd. HCl, insol. in 1:2 HCl, not attacked by cold alkalies, easily dissolves on heating, gives the Liebermann reaction with PhOH-H<sub>2</sub>SO<sub>4</sub>. The filtrate from the crude (a), greatly dild. with H<sub>2</sub>O, gives a yellow ppt. which, after 2 crystns. from dil. EtOH and once from dil. MeOH, gives 2 g. 3,4-O<sub>2</sub>N(Me<sub>2</sub>N)C<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>Me, m. 74°. From 1.9 g. (a) boiled 15 min. with 25 cc. of 2 N NaOH is obtained 1.4 g. MeN(NO)C<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H. Boiled 5 min. with concd. HCl, (a) gives MeNHC<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H, while boiling 0.5 hr. with MeOH satd. with HCl gives *p*-MeNHC<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>Me, m. 95.5° (Johnston.

C. A. 1, 812, gives 73–5°); it is also obtained from the acid or its HCl salt and from  $\text{MeN(NO)C}_6\text{H}_4\text{CO}_2\text{H}$  boiled with  $\text{MeOH-HCl}$ .  $p\text{-H}_2\text{NC}_6\text{H}_4\text{CO}_2\text{Me}$  (10.5 g.) boiled 0.5 hr. with 35 cc. of 2 N NaOH and 8.5 g.  $\text{Me}_2\text{SO}_4$ , cooled, filtered, dissolved in 50 cc. concd. HCl and 50 cc.  $\text{H}_2\text{O}$  and treated at  $-5^\circ$  with 7.5 g.  $\text{NaNO}_2$  in 20 cc.  $\text{H}_2\text{O}$ , gives 5 g. (a). In the same way from the Et ester is obtained  $\text{MeN(NO)C}_6\text{H}_4\text{CO}_2\text{Et}$ , needles with faint straw-yellow luster from dil. alc., m.  $55.5^\circ$ , gives  $\text{MeNHC}_6\text{H}_4\text{CO}_2\text{H}$  with boiling concd. HCl. (a) is also obtained from  $\text{MeNHC}_6\text{H}_4\text{CO}_2\text{Me}$  and  $\text{NaNO}_2$  in 2 N HCl at  $-5^\circ$ .  $p\text{-Me}_2\text{NC}_6\text{H}_4\text{CHO}$  (10 g.) in 50 cc. concd. HCl and 20 cc.  $\text{H}_2\text{O}$  treated at  $-12^\circ$  with 14 g.  $\text{NaNO}_2$  in 25 cc.  $\text{H}_2\text{O}$  evolves NO abundantly and gives a yellow ppt. which, after rubbing with 35 cc. concd. HCl and crystg. from  $\text{H}_2\text{O}$ , yields the hydrochloride (b), S-yellow crystals, m.  $178^\circ$  (decompn.), of  $p\text{-ONC}_6\text{H}_4\text{NMe}_2$ , green crystals from  $\text{Et}_2\text{O}$ , m.  $82^\circ$ . The filtrate from the crude (b) treated with soda till still just acid gives a ppt. which, when again treated with 1:1 HCl and repeatedly crystd. from dil. alc., yields *p*-methylnitrosaminobenzaldehyde, faintly straw-yellow, m.  $78^\circ$ . A further amt. of this is obtained by adding 35 cc.  $\text{H}_2\text{O}$  to the concd. HCl ext. of the crude (b); the filtrate from this 2nd crop, when greatly dild. and rendered somewhat less acid with soda, gives a ppt. of  $3,4\text{-O}_2\text{N}(\text{Me}_2\text{N})\text{C}_6\text{H}_3\text{CHO}$ , m.  $105^\circ$ . Assuming that tertiary amines add  $\text{HNO}_2$  coordinately in the Bamberger (*Ber.* 30, 2175(1899)) and Karrer (*C. A.* 9, 3239) sense, they would form compds. of the type  $\text{RC}_6\text{H}_4\text{NMe}_2(\text{OH})\text{NO}$  which, if the *p*-position is not occupied, would yield *p*-NO derivs. If the *p*-position is occupied, as in the above cases, the reaction is entirely different; there is a partial dealkylation (formation of  $\text{RC}_6\text{H}_4\text{NMeNO}$ ) and a partial nitration (formation of  $p\text{-O-R}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{NMe}_2$ ), i. e., the *p*-substituent has the same influence as increase in the size of the alkyl groups in the *p*-unsubstituted compds. Just as a *p*-substituent influences the additive power ("ammonization") of the N atom, so inversely the "ammonization" of the N atom strongly influences the *p*-carbon atom; there is almost always to a certain extent an elimination of the *p*-substituent and its replacement by the NO or  $\text{NO}_2$  group. The attempt to bring the reactivity of the *p*-carbon atom into relation with the conjugated double bond which is present (Karrer) does not explain the non-reactivity of the amine oxides and *o*-methylated tert. amines, which also contain such a conjugated double bond; this lack of activity can be explained on the assumption of the valence-chemically satd. state of the N atom. This assumption does not harmonize with the space-filling explanation of steric hindrance and the Bamberger view of antireactive substituent influence is more satisfactory. CHAS. A. ROULLER.

**Amine oxides.** OSKAR BAUDISCH. Techn. Hochschule, Zürich. *Ber.* 51, 1048–58(1918).—When 50 g. finely powdered  $p\text{-Me}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$  is slowly added to 430 cc. of a neutral soln. of  $\text{H}_2\text{SO}_4$  (417.2 cc. = 1 atom O), at  $0^\circ$ , filtered and allowed to stand overnight in the ice chest, there is obtained 45 g. of *p*-dimethylaminobenzoic acid *N*-oxide sulfate (a),  $(\text{HO}_2\text{CC}_6\text{H}_4\text{NMe}_2\text{:O}\dots\text{H})_2\text{SO}_4\cdot\text{H}_2\text{O}$ , long (2.5 cm.) feathery needles, m.  $160^\circ$  (foaming). Hydrochloride, obtained in 11 g. yield from 20 g. of (a) in 160 cc. HCl, needles, m.  $184^\circ$ ; 12 g. in 30 cc. hot  $\text{H}_2\text{O}$  treated with 60 g. KOAc in 50 cc.  $\text{H}_2\text{O}$  yields 3.8 g. of the free *N*-oxide, long (1 cm.) prismatic needles from  $\text{H}_2\text{O}$ , m.  $192.5^\circ$ . Chloroaurate,  $\text{HO}_2\text{CC}_6\text{H}_4\text{NMe}_2\text{:O}\cdot\text{HAuCl}_4$ , from (a) and 2 mols.  $\text{AuCl}_3$  in  $\text{H}_2\text{O}$ , red-yellow crystals from  $\text{H}_2\text{O}$ , m.  $136^\circ$ . Picrate, yellow needles from  $\text{H}_2\text{O}$ , m.  $155^\circ$ ; yield, 15.8 g. from 10 g. (a). Chloroplatinate, reddish white needles, m.  $155\text{--}6^\circ$ ; yield, 0.59 g. from 1.4 g. (a). Ferrocyanide, needles. When 3 g. of (a) in 50 cc. cold  $\text{H}_2\text{O}$  is satd. with  $\text{SO}_2$  there is pptd. 1.4 g. *p*-dimethylamino-*m*-sulfobenzoic acid, m.  $279\text{--}80^\circ$  (foaming), and the filtrate, freed from  $\text{SO}_2$  by boiling and satd. with NaOAc at  $0^\circ$ , yields 1.45 g.  $p\text{-Me}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ , m.  $242.5\text{--}3.5^\circ$ . The reaction probably follows the course: (a) +  $\text{H}_2\text{SO}_4 \rightarrow \text{HO}_2\text{CC}_6\text{H}_4\text{NMe}_2\text{:O}\dots\text{SO}_3\text{H} \rightarrow \text{HO}_2\text{CC}_6\text{H}_4\text{NMe}_2(\text{OH})\text{SO}_3\text{H} \rightarrow \text{HO}_2\text{CC}_6\text{H}_4\text{NMe}_2 + \text{HO}_2\text{CC}_6\text{H}_4(\text{SO}_3\text{H})\text{NMe}_2$ . Similarly, 10 g. (a) in 30 cc. concd.

HCl and 300 cc.  $\text{H}_2\text{O}$  treated with 3.1 g.  $\text{NaNO}_2$  in 10 cc.  $\text{H}_2\text{O}$  gives 2.2 g.  $p\text{-O}_2\text{NC}_6\text{H}_4\text{-NMe}_2$ , 4.8 g.  $3,4\text{-O}_2\text{N}(\text{Me}_2\text{N})\text{C}_6\text{H}_3\text{CO}_2\text{H}$  and 0.02 g.  $p\text{-ONC}_6\text{H}_4\text{NMe}_2$ . *m*-Amino-*p*-dimethylaminobenzoic acid hydrochloride, obtained in 2.8 g. yield from 4 g. of the  $\text{NO}_2$  acid reduced with  $\text{SnCl}_2$  in concd. HCl, long needles from alc., m.  $237^\circ$ , becomes faintly pink in the air, gives with a little  $\text{FeCl}_3$  a violet-red color; free acid, very faintly pink leaflets from ligroin, m.  $152\text{--}3^\circ$ . *p*-Diethylaminobenzoic acid *N*-oxide sulfate (b), obtained in 95 g. yield from 100 g.  $\text{Et}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$  and  $\text{H}_2\text{SO}_4$ , long needles with 1  $\text{H}_2\text{O}$ , m.  $173.5\text{--}4.5^\circ$ . Hydrochloride, needles from HCl, m.  $162.5\text{--}3.5^\circ$ . Free oxide, long needles from  $\text{H}_2\text{O}$ , m.  $170\text{--}1^\circ$  (foaming), loses AcH on dry heating. Chloroplatinate, reddish white needles, m.  $178^\circ$ . Chlorosaurate, golden yellow leaflets, m.  $177^\circ$ . Picrate, yellow needles, m.  $169\text{--}71^\circ$ . Ferrocyanide, leaflets turning green in the air. With  $\text{SO}_2$ , 5 g. (b) gives 3.1 g.  $\text{Et}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$  and 1.6 g.  $4,3\text{-Et}_2\text{N}(\text{HO}_2\text{S})\text{C}_6\text{H}_3\text{CO}_2\text{H}$ ; with  $\text{HNO}_3$  are obtained  $p\text{-O}_2\text{NC}_6\text{H}_4\text{N}(\text{NO})\text{Et}$ , straw-yellow needles, m.  $119.5\text{--}20.0^\circ$ ,  $p\text{-EtN}(\text{NO})\text{C}_6\text{H}_4\text{CO}_2\text{H}$ , m.  $192\text{--}3^\circ$ ,  $3,4\text{-O}_2\text{N}(\text{Et}_2\text{N})\text{C}_6\text{H}_3\text{CO}_2\text{H}$ , m.  $117^\circ$ ,  $3,4\text{-O}_2\text{N}(\text{EtNH})\text{C}_6\text{H}_3\text{CO}_2\text{H}$ , m.  $239\text{--}40^\circ$ , and  $p\text{-O}_2\text{NC}_6\text{H}_4\text{NEt}_2$ . CHAS. A. ROUVILLER.

*o*-Nitrosophenol. III. Preparation of *o*-nitrosophenol as a lecture experiment. OSKAR BAUDISCH. Ber. 51, 1058-9 (1918); cf. C. A. 10, 196.—A couple of crystals of  $\text{O}_2\text{NC}_6\text{H}_4\text{OH}$  in a few drops hot glacial AcOH are dild., after cooling, with a little  $\text{H}_2\text{O}$ , covered with a layer of petr. ether and treated with vigorous shaking with a couple particles of Zn dust. The petr. ether layer becomes emerald-green, the aq. soln. reddish. If the green petr. ether soln. is added to a very little dil. aq.  $\text{CuSO}_4$  it becomes colorless and the Cu soln. deep red. The petr. ether solns. are stable for a long time and the test for Cu which can be made with them is more sensitive than the  $\text{K}_3\text{Fe}(\text{CN})_6$  test. CHAS. A. ROUVILLER.

Isovaleric acid and its abnormal behavior in the Perkin synthesis. ALFRED SCHAARSCHMIDT, E. GEORGEACOPOL AND JOHANN HERZENBERG. Techn. Hochschule, Berlin. Ber. 51, 1059-74 (1918).— $\text{Me}_2\text{CHCH}_2\text{CO}_2\text{H}$  (a), although it has a  $\text{CH}_3$  group adjacent to the  $\text{CO}_2\text{H}$ , gives, under the usual conditions of the Perkin synthesis, none of the unsatd. acid but only, with loss of  $\text{CO}_2$ , the unsatd. hydrocarbon. The elimination of  $\text{CO}_2$  is effected with remarkable ease and at very low temps. ( $70\text{--}80^\circ$ ). That the formation of unsatd. acid does not precede that of the hydrocarbon is shown by the fact that the unsatd. acid in the free state does not lose  $\text{CO}_2$  at  $100^\circ$ . Thus, 15 g.  $\text{BzH}$ , 50 g.  $(\text{Me}_2\text{CHCH}_2\text{CO})_2\text{O}$  (b) and 45 g.  $\text{Me}_2\text{CHCH}_2\text{CO}_2\text{Na}$  (c) heated 30 hrs. at  $100\text{--}5^\circ$  give on steam distn. an oil which, when shaken with  $\text{NaHSO}_4$  and extd. with  $\text{Et}_2\text{O}$ , yields 9.3 g.  $\text{PhCH:CHCHMe}_2$  (d), b.  $195\text{--}200^\circ$ , while the residue in the distg. flask, on exact neutralization with HCl, slowly deposits in the cold 1.9 g.  $\alpha\text{-isopropylcinnamic acid}$  (e),  $\text{PhCH:C}(\text{CHMe}_2)\text{CO}_2\text{H}$ , leaflets or needles from very dil. alc., m.  $118.5^\circ$ . From 50 g.  $\text{BzH}$ , 175 g. (b) and 150 g. (c) heated 6 hrs. at  $150^\circ$  are obtained 46 g. (d); from 15 g.  $\text{BzH}$ , 55 g.  $\text{Ac}_2\text{O}$  and 45 g. (c) heated 30 hrs. at  $100\text{--}5^\circ$ , only 0.6 g. (d) and no (e); while from 15 g.  $\text{BzH}$ , 55 g. (b) and 45 g.  $\text{NaOAc}$  there were obtained 3.2 g. (d) and 11 g.  $\text{PhCH:CHCO}_2\text{H}$ . Furfural (50 g.), 175 g. (b) and 150 g. (c) after 5 hrs. at  $150^\circ$  give 32 g. furfuroisomylene,  $\alpha\text{-C}_6\text{H}_4\text{OCH:CHCHMe}_2$ , faintly yellowish oil, b.  $64\text{--}6^\circ$ , b.  $165\text{--}7^\circ$ , and 0.5 g. of the acid  $\text{C}_6\text{H}_4\text{OCH:C}(\text{CHMe}_2)\text{CO}_2\text{H}$ , scales from  $\text{H}_2\text{O}$ , m.  $114^\circ$ , sublimes easily, while 25 g. furfural, 75 g. (c) and 250 g.  $\text{Ac}_2\text{O}$  heated 7 hrs. at  $150^\circ$  give no hydrocarbon and 6 g.  $\text{C}_6\text{H}_4\text{OCH:CHCO}_2\text{H}$ , m.  $140^\circ$ .  $\text{O}_2\text{N-C}_6\text{H}_4\text{CHO}$ , (b) and (c), heated 10 hrs. at  $150\text{--}60^\circ$ , evolve no  $\text{CO}_2$  and form no unsatd. hydrocarbon; owing to the high temp. the reaction consists mainly in a resinification of the aldehyde. From 50 g.  $\text{O-HOC}_6\text{H}_4\text{CHO}$ , 90 g. (b) and 65 g. (c) after 20 hrs. at  $150\text{--}60^\circ$  are obtained 2.3 g. oil b.  $215\text{--}60^\circ$  and sepd. into 2 fractions, 0.9 g. b.  $215\text{--}30^\circ$  and 0.8 g. b.  $230\text{--}60^\circ$ , and only traces of an acid.  $p\text{-MeOC}_6\text{H}_4\text{CHO}$  (50 g.), 175 g. (b) and 150 g. (c) heated 8 hrs. at  $150\text{--}60^\circ$  yield 22 g.  $p\text{-MeOC}_6\text{H}_4\text{CH:CHCHMe}_2$ , b.

240–7°, and 3.1 g.  $\alpha$ -isopropyl-*p*-methoxycinnamic acid, needles from dil. alc., m. 134–5°. PhCH:CHCHO (15 g.), 50 g. (b) and 45 g. (c) heated 10 hrs. at 150–5° yield 2.2 g. oil b. 243–50°, 2 g. b. 250–7° and 1.5 g. of an acid, m. 145–7°. When Me<sub>3</sub>CHCHO, (b) and (c) are heated 36 hrs. at 150–60°, no unsatd. hydrocarbon or acid is formed; the only reaction consists in a polymerization of the aldehyde. CHAS. A. ROUVILLER.

A new benzanthrone synthesis. II. Conversion of 1-phenylnaphthalene-2,3-dicarboxylic anhydride into benzanthronecarboxylic acid. ALFRED SCHAARSCHMIDT AND ERNST KORTEN. Techn. Hochschule, Berlin. Ber. 51, 1074–82 (1918); cf. C. A. 11, 2797.—When 50 g. finely powdered 1,2,3-C<sub>10</sub>H<sub>6</sub>Ph(CO)<sub>2</sub>O are heated 3 hrs. at 155° with 750 g. of 91% H<sub>2</sub>SO<sub>4</sub>, poured into 3 l. H<sub>2</sub>O, heated to boiling and filtered hot, there is obtained 21.3 g. insol. material which, after treatment with alkali and 4 crystns. from PhNO<sub>2</sub>, yields 2.2 g. benzanthronecarboxylic acid (a), m. 347°. The filtrate, on cooling, deposits a *sulfoallochrysoketonecarboxylic acid* (b), C<sub>18</sub>H<sub>10</sub>O<sub>6</sub>S, in blood-red flocks, sol. in concd. H<sub>2</sub>SO<sub>4</sub> with red color but no fluorescence; *oxime*, lemon-yellow ppt., m. above 400°. Benzofluorenone (0.2 g.) heated in 10 cc. of 93% H<sub>2</sub>SO<sub>4</sub> 4 hrs. at 100° to appearance of the first distinct fluorescence, gives no ppt. on pouring into H<sub>2</sub>O, i. e., is completely converted into a sol. sulfonic acid; the same is true if it is heated 1 hr. at 100° or 1.5 hrs. at 50° while after 20 hrs. at room temp. the ketone is recovered unchanged. Allochrysoketonecarboxylic acid (c) treated with H<sub>2</sub>SO<sub>4</sub> at high temps. also gives (a) and (b). 1-Phenylnaphthalene-2,3-dicarboximide, obtained in 12.7 g. yield from 15 g. of the anhydride heated 1 hr. at 240–50° with NH<sub>3</sub> gas, thick needles from PhNO<sub>2</sub>, m. 249°; 1 g. heated 5 min. at 75° with 10 cc. of 93% H<sub>2</sub>SO<sub>4</sub>, gives (a), dark red flocks, and its orange-red *amide*, m. 281–2°. When 2.3 g. of the imide in 23 cc. concd. H<sub>2</sub>SO<sub>4</sub> is quickly heated to 130° (in the course of about 5 min.) and kept 5 min. more at this temp., it gives 0.8 g. benzanthronecarboxamide, m. 305°, 0.4 g. of a sulfonic acid difficultly sol. in cold H<sub>2</sub>O, and finally (c). III. ALFRED SCHAARSCHMIDT AND E. GEORGEACOPOL. Ibid 1082–7.—The method of prepn. of 3,4-benzofluorenone (allochrysoketone) (a) has been improved: 8 g. of the crystd. 1-carboxylic acid (allochrysoketonecarboxylic acid) is slowly heated above its m. p. in a 50 cc. retort at such a rate that the evolved CO<sub>2</sub> produces only a gentle foaming; when the mass becomes thick and the evolution of CO<sub>2</sub> slackens, the (a) is distd. over by rapid heating and crysts. in the neck of the retort to an orange mass; the whole operation lasts about 3 min. The product is rubbed with a little cold AcOH, washed with H<sub>2</sub>O, boiled with dil. NH<sub>4</sub>OH, filtered, washed and repeatedly crystd. from AcOH. When 5 g. (a) is gradually added to 40 g. molten KOH at 230–5° and stirred until a portion of the product dissolves completely in H<sub>2</sub>O (about 45 min.), cooled, dissolved in H<sub>2</sub>O, heated to boiling, nearly neutralized, filtered and acidified in the cold with dil. HCl there is pptd. a mixt. of the *acids* (I) and (II), sepd. by fractional crystn. from MeOH. The less sol.

acid (I) seps. in fine rhombohedrons, m. 161.5° (yield, about 1 g.); the isomer (1.2 g.) is very easily sol. in all solvents and without further purification was treated in 12 cc. C<sub>6</sub>H<sub>6</sub> with the calcd. amt. of PCl<sub>5</sub>, boiled 0.5 hr., cooled, slowly treated with 2.5 g. AlCl<sub>3</sub>, and heated 1 hr. at 60–5°; it gave the stable form of (a), m. 160°. The acid chloride of (I) with AlCl<sub>3</sub> gives benzanthrone; the latter is also obtained in 0.7 g. yield

from 0.8 g. *o*- $\alpha$ -C<sub>10</sub>H<sub>7</sub>C<sub>4</sub>H<sub>4</sub>CO<sub>2</sub>H converted into the chloride and treated with AlCl<sub>3</sub> as above, and in 0.9 g. yield by the dry distn. of the NH<sub>4</sub> salt of benzanthronecarboxylic acid.

CHAS. A. ROUILLET.

**Constitution of dioxalomalonic ester and other acylated acid esters.** KARL V. AUWERS AND ELISABETH AUFFENBERG. Marburg. *Ber.* 51, 1087-1106(1918); cf. *C. A.* 12, 693; Scholl and Egerer, *C. A.* 7, 2208.—v. A. and A., not agreeing with S. and E. that the fact that oxalomalonic esters lose CO on heating and do not instantly react with alk. KMnO<sub>4</sub> and undild. Br excludes the unsatd. structure RO<sub>2</sub>CC(O<sub>2</sub>CCO<sub>2</sub>R):C(CO<sub>2</sub>R)<sub>2</sub> and is compatible only with the pure ketone structure (RO<sub>2</sub>CCO)<sub>2</sub>C(CO<sub>2</sub>R)<sub>2</sub>, undertook to solve the question spectrochemically. They encountered two obstacles: (1) the difficulty in prepg. perfectly pure materials, and (2) compds. of such high mol. wt. and with so many groups containing O would have abnormally high mol. refractions even if they had the true dioxalomalonic ester structure. To det. the latter point, the following derivs. of CH(CO<sub>2</sub>H)<sub>3</sub> and C(CO<sub>2</sub>H)<sub>4</sub> of known structure were prepd. and their optical consts. detd.: CH(CO<sub>2</sub>Et)<sub>3</sub>, b<sub>14</sub> 139°, b<sub>15</sub> 145°, m. 27-9°, d<sub>4</sub><sup>20</sup> 1.104, n<sub>D</sub><sup>20</sup> 1.426, E<sub>Z</sub> 0.24, 0.21, 2%, 1% for  $\alpha$ , D,  $\beta$ — $\alpha$  and  $\gamma$ — $\alpha$  (unless otherwise stated, all the values for E<sub>Z</sub> are given in the above order). (MeO<sub>2</sub>C)<sub>2</sub>C(CO<sub>2</sub>Et)<sub>2</sub>, d<sub>4</sub><sup>20</sup> 1.180, n<sub>D</sub><sup>20</sup> 1.432, E<sub>Z</sub> 0.39, 0.40, 5%, 2%. C(CO<sub>2</sub>Et)<sub>4</sub>, b<sub>18</sub> 185°, d<sub>4</sub><sup>20</sup> 1.133, n<sub>D</sub><sup>20</sup> 1.434, E<sub>Z</sub> 0.36, 0.36, 3%, 4%. EtO<sub>2</sub>CCOC(CO<sub>2</sub>Et)<sub>2</sub>, b<sub>21</sub> 203°, d<sub>4</sub><sup>20</sup> 1.164, n<sub>D</sub><sup>20</sup> 1.438, E<sub>Z</sub> 0.48, 0.46, 7%. — The tricarboxylic ester, therefore, is alone optically normal while the refractive power of the compds. with 4 acid residues is distinctly increased; the values obtained, however, especially those for the dispersion, gave hope that the spectrochem. method could be applied to the problem under consideration. A prerequisite for obtaining pure tri-Et oxalomalonate (a) is the prepn. of its Na salt in pure form; the malonic ester and EtO<sub>2</sub>CCOCl must be specially purified; a com. sample of the latter, in spite of all possible attempts at purification, proved wholly unsuitable and success was attained only after it had been prepd. by the method of Anschütz and Schönfeld (*Ann.* 254, 20(1889)) or that of Diels and Nawiasky (*Ber.* 37, 3678(1904)). The free (a) was liberated from the Na salt with Et<sub>2</sub>O and ice-cold dil. H<sub>2</sub>SO<sub>4</sub> and purified according to the directions of S. and E.; as the oil cannot be distd. *in vacuo* dry air was passed through it under diminished pressure until the physical consts. did not change; it showed d<sub>4</sub><sup>20</sup> 1.153, n 1.44514, 1.44794, 1.45562, 1.46229 at 15.2° for  $\alpha$ , D,  $\beta$  and  $\gamma$ , n<sub>D</sub><sup>20</sup> 1.4458, E<sub>Z</sub> (calcd. on the basis of the ketone structure, EtO<sub>2</sub>CCOCH(CO<sub>2</sub>Et)<sub>2</sub>), 0.86, 0.89, 37%, 38%, E<sub>Z</sub> (on the basis of the enol structure, EtO<sub>2</sub>CC(OH):C(CO<sub>2</sub>Et)<sub>2</sub>), 0.47, 0.48, 25%, 27%; % enol by the Br titration method, 59.3-61.5. Tetra-Et dioxalomalonate (b), prepd. by S. and E.'s method except that an excess of the Na salt of (a) was used, which materially increased the yield and gave a pure product, showed d<sub>4</sub><sup>20</sup> 1.186, n<sub>D</sub><sup>20</sup> 1.455, n 1.45378, 1.45665, 1.46452, 1.47138 at 14.9° for  $\alpha$ , D,  $\beta$  and  $\gamma$ , E<sub>Z</sub> (on the basis of the ketone structure (EtO<sub>2</sub>CCO)<sub>2</sub>C(CO<sub>2</sub>Et)<sub>2</sub>), 1.14, 1.16, 36%, 35%, E<sub>Z</sub> (on the basis of the enol structure, EtO<sub>2</sub>CC(O<sub>2</sub>CCO<sub>2</sub>Et):C(CO<sub>2</sub>Et)<sub>2</sub>), 0.83, 0.84, 27%, 29%. The E<sub>Z</sub> values for MeC(OH):C(CO<sub>2</sub>Et)<sub>2</sub> (c) and MeC(OAc):C(CO<sub>2</sub>Et)<sub>2</sub> (d) are 0.44, 0.46, 28%, 31%, and 0.58, 0.59, 22%, 20%, resp. These values show that (a) and (c) are about equally enolized and that (b) is really an *O*-ester of (a) and should therefore more rationally be designated as triethyl ethoxalylloxethylene tricarboxylate. That the chem. behavior of (b) is not contrary to this structure was shown by a comparative study of the compds. MeC(O<sub>2</sub>CEt):CHCO<sub>2</sub>Et (e), (d), EtC(O<sub>2</sub>CEt):C(CO<sub>2</sub>Et)<sub>2</sub> (f), (b), EtO<sub>2</sub>CCOC(CO<sub>2</sub>Et)<sub>2</sub> (g) and C(CO<sub>2</sub>Et)<sub>2</sub> (h). About 0.25 cc. of each was shaken under as nearly identical conditions as possible with ice-cold 1% KMnO<sub>4</sub> and soda; with (e) the color disappeared immediately, with (d) somewhat more slowly, with (f) after about 0.25 min., with (b) after a somewhat longer interval, with (g) after about a min., while with (h) it persisted quite a long time. The

reaction can therefore be considered a criterion of unsatn. only at the two extremes of the series; for the intermediate members it is doubtful whether the gradual decolorization is due to a sterically delayed addition reaction of an unsatd. compd. or to the incipient hydrolysis of a satd. compd. Similar, though less marked, differences were observed when Br was dropped into the first 4 of the above compds. at  $-10^\circ$ . Neither the  $\text{KMnO}_4$  nor the Br reaction, therefore, yields decisive evidence as to the structure of (b). Also, the present work shows that not only ketones but enols also may lose CO at high temps. The formation of not quite pure propionyl- and acetylphenylhydrazine by the action of  $\text{PhNHNH}_2$  on the propionyl ester of acetylmalonic ester and the isomeric Ac ester of propionylmalonic ester, resp., had been ascribed formerly to the possible presence in the malonic ester of small amts. of the true diacyl derivs., although it was considered more probable that the formation of the by-products was due to a more deep-seated decompn. The latter assumption has been verified, as pure acetylmalonic ester in ice-cold soln. gives some acetylphenylhydrazine, the ester being decompd. by  $\text{PhNHNH}_2$  just as it is by alkalis, although more slowly. Similarly propionylmalonic ester (1 g.) gives a little (0.15 g.) propionylphenylhydrazine. As S. and E. likewise deduced the constitutions of their acylmethanetricarboxylic esters from their behavior towards  $\text{KMnO}_4$  and Br, v. A. and A. have studied a representative of this class of compds. by the spectrochem. method. Tri-Et acylmethanetricarboxylate (i),  $b_{11}$  153-5°,  $d_4^{20}$  1.121,  $n_D^{20}$  showed 1.433,  $E\epsilon$  0.37, 0.36, 5%, 4% (on the basis of the ketone structure), indicating beyond doubt that it really is the satd. Ac deriv. According to Claisen's views, starting from malonic ester, a pure C-deriv. or pure O-ester can be obtained at will by the introduction of a  $\text{CO}_2\text{Et}$  and an acyl group according to the order in which the 2 groups are introduced:  $\text{CH}_2(\text{CO}_2\text{Et})_2 \rightarrow \text{AcCH}(\text{CO}_2\text{Et})_2 \rightarrow \text{MeC}(\text{OH})\text{:C}(\text{CO}_2\text{Et})_2 \rightarrow \text{MeC}(\text{OCO}_2\text{Et})\text{:C}(\text{CO}_2\text{Et})_2$ , and  $\text{CH}_2(\text{CO}_2\text{Et})_2 \rightarrow \text{CH}(\text{CO}_2\text{Et})_2 \rightarrow \text{AcC}(\text{CO}_2\text{Et})_2$ , and as a matter of fact it was found that the product obtained by treating di-Et acetylmalonate with  $\text{ClCO}_2\text{Et}$  under various conditions (as the Na salt in  $\text{Et}_2\text{O}$ , the Cu salt in  $\text{C}_6\text{H}_6$  suspension, and finally in  $\text{C}_6\text{H}_5\text{N}$ ) was not identical with (i) but was the isomeric diethyl o-carbethoxyethylidene-malonate,  $b_{11}$  166°,  $d_4^{20}$  1.127,  $n_D^{20}$  1.448,  $E\epsilon$  (on the basis of the enol structure), 0.50, 0.51, 19%, 19%.

CHAS. A. ROUILLER.

**Constitution of phthalyl- and succinylmalonic ester.** KARL V. AUWERS AND ELISABETH AUFFENBERG. Marburg. *Ber.* 51, 1106-15 (1918); cf. preceding abstr. —In order to det. between the sym. and unsym. structures of phthalylmalonic ester (a) its optical consts. have been detd. and compared with those of 2,2-diethylindandione (b) and 4,7-dimethyl-2,2-diethylindandione (c). (a) m. 74-5°,  $d_4^{24.4}$  1.1887,  $n$  1.53416, 1.54105, 1.56155 for  $\alpha$ , D and  $\beta$  at 84.4°,  $E\epsilon$  (on the basis of the sym. formula) 2.52, 2.66, 137%,  $E\epsilon$  (on the basis of the unsym. formula) 2.13, 2.25, 122%, for  $\alpha$ , D and  $\beta - \alpha$ . (b) (still containing 2% Cl),  $b_{11}$  157-9°,  $d_4^{14.6}$  1.0693,  $n_D^{20}$  1.5393,  $E\epsilon$  1.43, 1.49, 54%, 37% for  $\alpha$ , D,  $\beta - \alpha$  and  $\gamma - \alpha$ . (c), m. 51-2°,  $b_{11}$  153°,  $d_4^{22.4}$  1.0174,  $E\epsilon$  1.56, 1.63, 63% for  $\alpha$ , D and  $\beta - \alpha$ . These results show that (a) has a spectrochem. character entirely different from that of (b) and (c) and therefore has not the sym. structure. As an unsym. compd. it may perhaps be compared with benzalmalonic ester, for which  $E\epsilon$  is 1.62, 1.73, 90%, 101% for  $\alpha$ , D,  $\beta - \alpha$  and  $\gamma - \alpha$ ; in comparing (a) and (d) it should be remembered that (a) contains a conjugation as well as a disturbance ("Störung") more than (d), the one tending to increase, the other to decrease the exaltations. Moreover, aromatic bicyclic ketones (as shown in the case of (b) and (c)) have higher exaltations than monocyclic ketones of analogous structure. Finally the optical consts. of the solid (a) had to be detd. at a high temp. (84.4°), which would also increase the exaltations. The numerical magnitude of all these factors cannot be forecast with certainty and it can only be said that the results indicate

similarity of structure between (a) and (d). To test this point further it would have been desirable to compare  $\text{PhCH:CH}_2$  and  $\text{C}_6\text{H}_4\text{C}(\text{:CHMe})\text{O.CO}$  (e), which stand to

each other in the same relation as (a) and (d), but (e) at temps. above its m. p. polymerizes in a few moments to an exceedingly viscous mass so that no exact detns. could be made. Nevertheless it was established that (e) has considerably higher refractive and dispersive powers than  $\text{PhCH:CH}_2$ .  $\text{C}_6\text{H}_4\text{C}(\text{:CHMe})\text{O.CO}$ , m.  $64^\circ$ ,  $d_4^{20}$  1.1053, shows  $EZ$

2.29 and 2.36 for  $\alpha$  and D, and  $\text{PhCH:CHMe}$  shows 1.09 and 1.19, the lactone ring, therefore, producing a powerful increase in the exaltations. The optical consts. of (a) do not wholly exclude the structure  $\text{C}_6\text{H}_4\text{CO.C(CO}_2\text{Et):C(OEt).O.CO}$ , considered by

Scheiber (*C. A.* 6, 2077), but this has but slight probability on chem. grounds. Succinylmalonic ester, m.  $68^\circ$ ,  $d_4^{24}$  1.1684, shows  $EZ$  1.60, 1.63, 58%, 57% on the basis of the sym. structure and 1.13, 1.15, 41%, 42% on the basis of the unsym. structure; the high exaltations exclude the sym. structure with certainty. The compd. obtained from this ester and  $\text{PhNHNH}_2$  has the compn.  $\text{C}_{21}\text{H}_{22}\text{O}_4\text{N}_4$  and not  $\text{C}_{21}\text{H}_{20}\text{O}_4\text{N}_4$  as originally given by Scheiber (who subsequently corrected his earlier statement; *C. A.* 5, 3815). As in the case of (a) the optical data do not exclude the structure  $\text{O.CO.CH}_2\text{CH}_2\text{CO.C(CO}_2\text{Et):COEt}$ .

CHAS. A. ROULLER.

**Spectrochemical communications. I. Polyketo compounds. K. v. AUWERS.** Marburg. *Ber.* 51, 1116-24(1918).—In connection with the study of dioxalomalonic ester (first of the 2 preceding abstrs.) it became necessary to det. whether in a compd. of the type  $(\text{EtO}_2\text{CCO})_2\text{C(CO}_2\text{Et})_2$  exaltations of the specific refraction and dispersion were to be expected, and if so, of what magnitude, as such a compd. contains the doubly disturbed ("gestörte") conjugation  $\text{EtOC(:O)C(:O)OEt}$ .  $\text{Ac}_2$ ,  $d_4^{13.46}$  0.9809, showed  $EZ$  0.42, 0.41, 9% for  $\alpha$ , D and  $\beta - \alpha$ ;  $(\text{CO}_2\text{Et})_2$ ,  $d_4^{15.76}$  1.0834, gave 0.27, 0.27, 4%, 4% for  $\alpha$ , D,  $\beta - \alpha$  and  $\gamma - \alpha$ . Thus,  $\text{Ac}_2$ , with the less disturbing Me groups, shows distinct exaltations, while in  $(\text{CO}_2\text{Et})_2$ , with the more strongly disturbing OEt groups, the anomaly due to the 2 conjugated C:O groups almost disappears. Even assuming that in a C,C-dioxalomalonic ester the optical effect of the 2 conjugated groups is doubled, which by analogy is not probable, this would not suffice to explain the great exaltations (especially of the dispersion—about 28%) actually found, thus further confirming the view that the compd. is an unsatd. O-ester. To det. the spectrochem. influence of 3 and 4 adjacent C:O groups, the 3 following compds. were studied:  $\text{AcCOCO}_2\text{Et}$ ,  $b_{11}$  77-80°,  $d_4^{15.8}$  1.1289,  $EZ$  0.60, 0.60 for  $\alpha$  and D;  $\text{CO(CO}_2\text{Et})_2$ ,  $b_{11}$  105-7°,  $d_4^{15.8}$  1.1419,  $EZ$  0.57, 0.56, 10% for  $\alpha$ , D and  $\beta - \alpha$ ;  $(\text{COCO}_2\text{Et})_2$ ,  $b_{11}$  120-2°,  $d_4^{16.9}$  1.1845,  $EZ$  0.68, 0.68 for  $\alpha$  and D (the d. and  $n$  increase somewhat and the color deepens after each distn.). These detns. are somewhat uncertain as these compds. are all very hygroscopic and do not distil entirely undecompd. *in vacuo*, but the influence of the 3rd and 4th C:O groups is unmistakable. The effect of a C:O group adjacent to a conjugation —C:C:O already present is similar;  $\text{PhAc}$  (*C. A.* 7, 480),  $EZ$  0.60, 0.65 for  $\alpha$  and D;  $\text{BzAc}$ ,  $b_{11}$  101.6-2.6°,  $d_4^{15.8}$  1.1083,  $EZ$  1.01, 1.05;  $\text{BzCOAc}$ ,  $d_4^{17.2}$  1.1801,  $EZ$  1.37, 1.45 (the triketone is very hygroscopic and the detns. are not very certain). As the 2 polyketones are so colored that the dispersion could not be measured, the following compds. were also compared: 5,2-Me(MeO) $\text{C}_6\text{H}_2\text{COAc}$ ,  $EZ$  0.94, 54% for  $\alpha$ , D and  $\beta - \alpha$ ; 5,2-Me(MeO) $\text{C}_6\text{H}_2\text{COAc}$ , m. 60-1°,  $d_4^{16}$  1.1193,  $EZ$  1.27, 1.35, 80%; methyl-p-cresyl diketone ethyl ether, 5,2-Me(EtO) $\text{C}_6\text{H}_2\text{COAc}$ , prisms from MeOH or ligroin, m. 63-4°,  $d_4^{15}$  1.0524,  $EZ$  1.46, 1.53, 78%, prepd. from o-propionyl-p-cresyl ethyl ether (from the cresol and alk.  $\text{Et}_3\text{SO}_4$ ), prisms from MeOH, m. 50-1°, through the oxime, needles from dil. MeOH, m. 105-6°. Finally,  $\text{BzCO}_2\text{Et}$ ,  $b_{11}$  128-31°.

$b_m$  158–63°,  $d_4^{13.35}$  1.1255,  $EZ$  0.89, 0.84, 46%, 52% for  $\alpha$ , D,  $\beta - \alpha$  and  $\gamma - \alpha$ , may be compared with  $BzCHMe_3$ ,  $EZ$  0.51, 0.53, 28%, 31%, and  $BzOEt$ ,  $EZ$  0.43, 0.49, 26%, 26%. II. Allenes and ketenes. *Ibid* 1124–8.—Contrary to Brühl (*C. A.* 1, 1537) and in agreement with Merezhkovskii (*C. A.* 8, 1420) it has been found that compds. with cumulated double bonds between C atoms are not spectrochemically normal but show moderate exaltations in refraction and dispersion which, however, are much smaller than in compds. with conjugated double bonds. Thus  $Me_2C:C:CH_3$ ,  $b$  39–40.5°,  $d_4^{13.6}$  0.6913, shows  $EZ$  0.60, 0.59, 21%, 18% for  $\alpha$ , D,  $\beta - \alpha$  and  $\gamma - \alpha$ . On the other hand, the cumulation  $-C:\dot{C}:O$  exerts no marked spectrochem. influence as shown in the comparison of  $Ph_3C:C:O$ ,  $d_4^{13.7}$  1.1107,  $EZ$  0.86, 0.92 for  $\alpha$  and D, with  $Ph_3C:O$ ,  $EZ$  0.91, 1.00, and  $Ph_3C:CH_3$ ,  $EZ$  0.88, 0.95, and in the values for  $Et_3C:-C:O$ ,  $b$  88–9.5°,  $d_4^{13.55}$  0.8366, for which  $EZ$  is —0.08, —0.09, —2% for  $\alpha$ , D and  $\beta - \alpha$ . The values for the polymer of the last compd.,  $Et_3C.CO.CEt_3.CO$ ,  $b_m$  115–7°,  $b$  230°,

$d_4^{16.65}$  0.9463,  $EZ$  0.27, 0.25, 4%, 1% for  $\alpha$ , D,  $\beta - \alpha$  and  $\gamma - \alpha$ , are about normal, the 4-membered ring producing a slight exaltation, perhaps somewhat increased by the two C-O groups, while the two *gem*- $Et_3$  groups exert an influence in the opposite direction. III. Spectrochemical technic. *Ibid* 1128–33.—In detg. the  $d$ . in the molten state of high melting substances v. A. uses an Ostwald pycnometer, one capillary of which is provided with a mm. scale instead of a single mark. The molten substance having been heated more or less (depending on the size of the pycnometer) above the temp. at which the detn. is to be made, it is drawn into the pycnometer which is then suspended in a bath of glycerol or other high boiling solvent heated approximately to the desired temp. When the liquid in the graduated capillary becomes stationary, which it does very quickly, its position is read with a lens. The pycnometer is calibrated in the usual way. Detns. accurate to within 1 or 2 units in the 4th decimal place can be made with a pycnometer of 0.5 cc. capacity. Of course, at high temps. there is an unavoidable error owing to the fact that the portion of the liquid in the arm of the pycnometer projecting outside of the bath is somewhat cooler than the main portion; it was found that under the most unfavorable conditions (*i. e.*, when the vol. of liquid not immersed in the bath was about 10% of the total vol.) at temps. of about 80° with substances having a  $d$ . of about 1, the error was about 2 units in the 3rd decimal place.

CHAS. A. ROUILLER.

**Bases of the julolidine type.** J. v. BRAUN, KARL HEIDER AND WANDA WYCZATKOWSKA. Univ. Breslau and Warschau. *Ber.* 51, 1215–27(1918); cf. *C. A.* 11, 806, 2785.—*Lilolidine* (I), obtained in 40% yield from dihydroindole gently boiled 18 hrs. with 6 parts  $ClCH_2CH_2CH_2Br$  (a), treated with HCl, freed from unchanged (a) with steam, made alk. and again distd. with steam,  $b_m$  156°, becomes reddish in the air; *picrate*,  $m$ . 138°; *methiodide*. With  $BzH$  in the presence of  $ZnCl_2$  (I) condenses almost as easily as  $PhNMe_3$  and on short warming with chloranil develops an intense malachite-green color; with 0.5 mol.  $HCHO$  on the  $H_2O$  bath it gives a thick, oily base not volatile with steam, recognized as the  $CH_3Ph_3$  deriv.  $CH_3(C_{11}H_{13}N)_3$ , by the blue-violet color produced with  $PbO_2$ . When the methiodide is converted by  $AgCl$  into the chloro-

methylate and the concd. soln. of the latter is treated with twice the calcd. amt. of 5% Na-Hg, it gives (I) exclusively; the simultaneous attachment of the pyrrolidine and piperidine rings to the  $C_6H_4$  nucleus, therefore, markedly increases its stability, Na-Hg merely splitting off the Me group of the chloromethylate.  $\alpha$ -Methyldihydroindole gently boiled 4-5 hrs. with 5-6 parts (a) gives a brown-red cryst. magma consisting chiefly of *N*- $\gamma$ -chloropropyl- $\alpha$ -methyldihydroindole hydrobromide which, on acidification, extn. with  $Et_2O$  to remove the excess of (a), treatment with alkali and distn. with steam, yields the free base,  $b_{18}$  172-5°, faintly yellow liquid changing with extraordinary rapidity, becoming dark, then turbid and depositing a solid. If the heating with (a) is continued 18 hrs. the product is  $\alpha'$ -methyllulolidine (II) (yield, 40%).  $b_{18}$  165-7°, soon darkening; *picrate*, m. 140°; *methiodide*, m. 202°. Towards BzH and HCHO, (II) behaves like (I) and with  $FeCl_3$  and other oxidizing agents gives the red color characteristic of the ring-homolog julolidine. When the chloromethylate is treated in the usual way with Na-Hg and the resulting basic reduction product is heated 15 hrs. in HCl with 0.5 mol. HCHO, made alk. and distd., only about 10% passes over as *o*-propyl- $\alpha$ ,*N*-dimethyldihydroindole (III),  $b_{18}$  151°; *picrate*, yellow needles from alc., m. 121°; *chloroplatinate*, yellow-red, m. 177-8°; *methiodide*, oily. (III) is perfectly stable, does not darken even after weeks, gives no red color with oxidizing agents and no malachite-green color on treatment with BzH and subsequent oxidation, only a violet color resulting after long treatment with the BzH; that the N is still in aromatic combination as in (II) is shown by nitrating in excess of  $H_2SO_4$ ; on making alk. with soda a  $NO_2$  deriv. with the  $NO_2$  group in the *m*-position to the basic N seps. as a red-brown oil; this on reduction with  $SnCl_2$  gives the solid HCl salt of a base showing the typical reactions of a *m*-diamine (intense red color with  $HNO_3$ , beautiful toluylene-blue and -red reaction with  $ONC_4H_9NMe_2$ ). The structure (III) is further confirmed by the fact that the compd. is not identical with *o*-propylkairoline (IV), which was synthesized by heating *o*- $PrC_6H_4NH_2$  in  $H_2SO_4$  with glycerol and  $H_3AsO_4$  3 hrs., making alk., distg. with steam and diazotizing; the resulting *o*-propylquinoline, light yellow liquid,  $b_{18}$  142° (yield, 35%); *chloroplatinate*, m. 196°; *picrate*, yellow-red needles from alc., m. 142°; *methiodide*, m. 136°. Reduction of the methiodide with Sn and HCl gives (IV) which shows a faint but distinct fluorescence in  $Et_2O$ ; *picrate*, deep red, m. 108-9°; *chloroplatinate*, deep red cryst. powder, m. 164°. Julolidine (V) (Pinkus, *Ber.* 25, 2798

(1892)), obtained pure in almost theoretical yield by heating tetrahydroquinoline and (a) 8 hrs. instead of 1.25 hrs. as given by P.,  $b_{17}$  155-6°, without decompn., easily gives with BzH the malachite-green reaction; heated 15 hrs. with 0.5 mol. HCHO it forms an oily diphenylmethane deriv., which with excess of MeI, however, yields a cryst. *dimethiodide*,  $C_{27}H_{28}N_2I_2$ , m. 228°. Equal parts of (V) and MeI after 8 hrs. at room temp. give 16% methiodide; the corresponding quaternary hydroxide on distn. (best *in vacuo*) loses MeOH and regenerates pure (V). When the chloromethylate in concd. soln. is treated with twice the calcd. amt. of 5% Na-Hg there is obtained 80% of a basic mixt. consisting of 63% (V) and 37% of a base to which is assigned the unusual structure (VI); (VI) is isolated from the mixt. by the HCHO method and forms an almost colorless liquid of faint odor,  $b_{22}$  144-8°; *picrate*, yellow needles from alc., begins to

decomp. above  $180^{\circ}$ , m.  $189^{\circ}$ ; chloroplatinate, m.  $191^{\circ}$ ; methiodide, m.  $200^{\circ}$ . (VI) gives no trace of color with oxidizing agents, does not condense with BzH to a malachite green-like dye, is unstable towards  $\text{KMnO}_4$  in  $\text{H}_2\text{SO}_4$  but does not take up a trace of H on shaking with Pd. Treated with the amt. of  $\text{KMnO}_4$  calcd. for the destruction of the complex  $\text{C}_7\text{H}_{12}\text{N}$  it gave a small amount of an acid which, from its soly., m. p. (above  $300^{\circ}$ ) and long hair-like crystals, was identified, with reasonable certainty, as  $m\text{-C}_6\text{H}_4(\text{CO}_2\text{H})_2$ . Nitration in  $\text{H}_2\text{SO}_4$  gives an oily  $\text{NO}_2$  deriv. which on reduction yields no product showing in the slightest degree the reactions of a  $m$ -diamine. The quaternary hydroxide (from the methiodide) on distn. does not lose MeOH but  $\text{H}_2\text{O}$  and yields a base  $\text{C}_{14}\text{H}_{22}\text{N}$ , b.  $117-8^{\circ}$ , b.  $164-70^{\circ}$ , which soon becomes red-brown; the hydrochloride, picrate, chloroplatinate and methiodide are all oily. The base has a marked aliphatic odor, immediately decolorizes  $\text{KMnO}_4$  in  $\text{H}_2\text{SO}_4$  at  $0^{\circ}$  and absorbs H in the presence of Pd. It is provisionally assigned the structure of  $\gamma$ - $m$ -allylphenylpropyldimethylamine,  $\text{CH}_2\text{:CHCH}_3\text{C}_6\text{H}_4\text{CH}_2\text{CH}_2\text{CH}_2\text{NMe}_2$ .

CHAS. A. ROUILLER.

**Rearrangement of arylhydroxylamines into aminophenols.** F. KLAUS AND O. BAUDISCH. *Ber.* 51, 1228-30(1918).—From 3 g.  $m\text{-Me}(p\text{-MeC}_6\text{H}_4\text{SO}_2)\text{NC}_6\text{H}_4\text{NHOH}$  slowly added with vigorous stirring to 17 g. concd.  $\text{H}_2\text{SO}_4$  and 60 g. ice, then dild. with 175 cc.  $\text{H}_2\text{O}$ , heated 30 min. on the  $\text{H}_2\text{O}$  bath, then 15 min. over a free flame, filtered when the  $\text{NH}_2\text{OH}$  reaction (red color imparted to the  $\text{Et}_2\text{O}$  when 1-2 cc. of the soln. is shaken under  $\text{Et}_2\text{O}$  with 1 drop each of  $\text{FeCl}_3$  and  $\text{NaNO}_2$ ) is no longer given, partly neutralized with soda and treated with  $\text{NaOAc}$ , is obtained  $p$ -amino-[methyl- $p$ -toluene sulfonylamino]phenol,  $\text{H}_2\text{N}(\text{MeC}_6\text{H}_4\text{SO}_2\text{NMe})\text{C}_6\text{H}_4\text{OH}$ , m.  $163-4^{\circ}$ , easily sol. in dil. acids, gives an intense violet color with  $\text{FeCl}_3$ , reduces  $\text{NH}_4\text{-AgNO}_3$  energetically, couples with phenols after diazotization. Similarly from  $o$ , $p$ - $\text{MeC}_6\text{H}_4\text{SO}_2\text{C}_6\text{H}_4\text{NHOH}$  is obtained 2-amino-5-hydroxyphenyl  $p$ -toluenesulfonate sulfate, m.  $162^{\circ}$ ; hydrochloride, needles from alc.- $\text{Et}_2\text{O}$ , m.  $187-90^{\circ}$ . The base couples, after diazotization, with  $\beta$ -naphthol, forming a dark red dye.

CHAS. A. ROUILLER.

**Rearrangement reactions in the anthraquinone-fluorenone series.** ALFRED SCHAARSCHMIDT AND JOHANN HERZENBERG. *Techn. Hochschule, Berlin. Ber.* 51, 1230-7(1918); cf. *C. A.* 11, 2797.—1-Chloro-2-benzoylanthraquinone (a), yellow leaflets from AcOH, m.  $196^{\circ}$ , is obtained in 12 g. yield from 16.5 g.  $1,2\text{-C}_6\text{H}_4(\text{CO})_2\text{C}_6\text{H}_4\text{ClCO}_2\text{H}$  by boiling 1 hr. in 90 cc. PhMe with 16 g.  $\text{PCl}_5$ , suspending the resulting chloride (15 g. light yellow needles) in 100 cc.  $\text{C}_6\text{H}_6$ , adding 16 g.  $\text{AlCl}_3$  in the course of 45 min. with shaking, heating 4 hrs. at  $60^{\circ}$ , decomp. with ice, removing the  $\text{C}_6\text{H}_6$  with steam and boiling the crude ketone with HCl and then with dil. soda. Heated 5 hrs. at  $170-3^{\circ}$  with 50 cc. alc. and 22 cc. aq.  $\text{NH}_4\text{OH}$ , 8.5 g. (a) yields 7.5 g. 1-amino-2-benzoylanthraquinone, red needles from AcOH, m.  $190^{\circ}$ ; when 30 g. in 330 cc. concd.  $\text{H}_2\text{SO}_4$  at  $5-10^{\circ}$  are slowly treated with 250 g.  $\text{HNO}_3\text{-H}_2\text{SO}_4$  (corresponding to about 8 g.  $\text{NaNO}_2$ ) at such a rate that the temp. does not rise above  $17-22^{\circ}$ , stirred 45 min. at room temp. after a test portion introduced into  $\text{H}_2\text{O}$  gives no more red ppt., poured in a thin stream upon ice at such a rate that the temp. remains below  $35^{\circ}$ , treated with 10 g. Cu powder, heated 2 hrs. on the  $\text{H}_2\text{O}$  bath, brought to a boil, filtered, washed with hot  $\text{H}_2\text{O}$  and freed from the last traces of Cu with warm 2%  $\text{HNO}_3$ , there is obtained 29 g. anthraquinone-2,1-fluorenone (I), golden yellow leaflets from  $\text{PhNO}_2$ , m.  $317^{\circ}$ , forms an intensely red vat dye with  $\text{Na}_2\text{S}_2\text{O}_4$ . If to 80 g. KOH at  $220-5^{\circ}$  8 g. (I) are added in the course of 0.5 hr., kept 10 min. longer at the same temp., boiled up with  $\text{H}_2\text{O}$ , filtered and acidified with HCl a small amt. of brown yellow flocks (b) is obtained which m.  $115-20^{\circ}$  and then evolve gas (probably  $\text{CO}_2$ ) energetically, give an intensely red vat dye with  $\text{Na}_2\text{S}_2\text{O}_4$ . The HCl filtrate yields not inconsiderable amts. of BzOH. Heated 2 hrs. on the  $\text{H}_2\text{O}$  bath with 10 parts  $\text{H}_2\text{SO}_4$ , then allowed to stand 10 days at room temp. and poured into  $\text{H}_2\text{O}$  (b) gives a product which, contrary to (b), is only partially sol. in

alkalies,  $\text{Et}_2\text{O}$ , alc., etc. Boiled with alc. and filtered hot, the insol. portion seps. from  $\text{PhNO}_2$  in red-yellow needles (c), m.  $351^\circ$ , insol. in alkalies, seps. from concd.  $\text{H}_2\text{SO}_4$  on addition of  $\text{H}_2\text{O}$  in orange-yellow flocks sol. in alk.  $\text{Na}_2\text{S}_2\text{O}_4$  with intense green color; the substance is identical with Ullmann and Desgupta's anthraquinone-2,3-fluorenone (C. A. 8, 1584). The hot alc. ext. of the crude (c), on evapn. to dryness and crystn. from  $\text{PhMe}$ , yields light yellow needles (d), m.  $235-40^\circ$ , sol. in alkalies with light red color and in  $\text{Na}_2\text{S}_2\text{O}_4$  with intense red color. The analysis of the not quite

pure Ag salt of (b) (which gave values intermediate between those for a mono- and a di- $\text{CO}_2\text{H}$  acid) and the red color of its soln. in  $\text{Na}_2\text{S}_2\text{O}_4$  indicate the presence of a small amt. of a monobasic acid (II), but the formation of (c) on condensing (b) with  $\text{H}_2\text{SO}_4$  shows that the action of the KOH on (I) did not stop with the formation of (II) but also opened the anthraquinone ring and gave considerable amts. of a dibasic acid (III). (d) is probably a monobasic acid with the anthraquinone nucleus formed as an intermediate product in the condensation of (III) to (c).

CHAS. A. ROUILLER.

**Reduction of methyl formylphenylacetate to methyl tropate.** WILHELM WISLICHENUS AND ERNST A. BILHUBER. Univ. Tübingen. *Ber.* 51, 1237-8(1918); cf. Müller, C. A. 12, 2556.—M.'s "new synthesis of tropic acid" is based on W.'s reduction method (C. A. 3, 790) and the "synthesis of tropic acid" was effected in W.'s lab. in 1915 (Bilhuber, *Diss. Tübingen*, 1915, 41), in the course of which was obtained *methyl tropate* (a). Four g.  $\text{HCOCHPhCO}_2\text{Me}$  in 10 parts abs.  $\text{Et}_2\text{O}$  were treated with a large excess of Al-Hg (activated), then slowly with  $\text{H}_2\text{O}$  with stirring until, after several hrs., the  $\text{FeCl}_3$  reaction of the soln. had disappeared; after standing some further length of time it was filtered and evapd.; there remained 2.4 g. (a) as a colorless oil, b<sub>p</sub>  $159-62^\circ$ , m.  $36.5-7.5^\circ$ ; 2 g. boiled a few min. with 0.26 g. Na in 8 cc. MeOH and 0.3 g.  $\text{H}_2\text{O}$  gave 1.3 g. Na *dl*-tropate which on short warming with a slight excess of dil.  $\text{H}_2\text{SO}_4$  and extrn. with  $\text{Et}_2\text{O}$  gave 80% of the acid, needles or rhombic tablets from  $\text{H}_2\text{O}$ , m.  $117-8^\circ$ .

CHAS. A. ROUILLER.

**Naphthylacetic acids. III. 1-Nitronaphthyl-2-pyruvic acid and 1-nitronaphthyl-2-acetic acid.** FRITZ MAYER AND TRUDI OPPENHEIMER. Univ. Frankfurt a/M. *Ber.* 51, 1239-45(1918); cf. C. A. 12, 2566.—From 5 g.  $1,2\text{-C}_{10}\text{H}_7(\text{NO}_2)\text{CH}_2\text{COCO}_2\text{H}$  (a) and 1.6 g. NaOH in 100 cc. cold  $\text{H}_2\text{O}$  treated with a soln. of 4 g.  $\text{KMnO}_4$ , were obtained 1.5 g. *1-nitro-2-naphthaldehyde*, leaflets from ligroin, m.  $99^\circ$ , volatile with steam, and 1.2 g. of the acid (b), brown powder, m.  $239^\circ$ , reduced by  $\text{FeSO}_4\cdot\text{NH}_4\text{OH}$  to the  $\text{NH}_2$  acid, m.  $202-5^\circ$ . Treatment of (a) with Br-NaOH likewise gave (b). With  $\text{FeSO}_4\cdot\text{NH}_4\text{OH}$ , (a) gives  $\alpha$ -naphthindolecarboxylic acid, m.  $213^\circ$ ; Na-Hg yields the same product. When 5 g. (a) heated in 10 parts  $\text{H}_2\text{O}$  and 15 g. of 10% HCl are treated with 1.4 g.  $\text{NaNO}_2$  in a little  $\text{H}_2\text{O}$  there is obtained a compd. m.  $131^\circ$  which does not yield  $\text{HOCH}_2\text{H}_5\text{CO}_2\text{H}$  when boiled with  $\text{H}_2\text{O}$  and which is thought to be *1-nitro-2-naphthylacetone-nitrile*. If 5 g. (a) in a little 20% NaOH and 300 cc.  $\text{H}_2\text{O}$  is distd. with steam, some  $\text{O}_2\text{NC}_{10}\text{H}_7\text{Me}$  passes over; when this ceases to distil, the residue is filtered and acidified, whereupon a brown substance turning red in the air seps.; this, when boiled with  $\text{NaHSO}_3$ , gives a substance which yields 2 compds., depending on whether it is decompd.

by cold or hot  $\text{H}_2\text{SO}_4$ ; in the cold is formed *1-nitro-2-naphthylacetaldehyde*, yellow crystals from alc., m.  $212^\circ$ , which on treatment with  $\text{PhNHNH}_2$  apparently undergoes an oxidation similar to that in osazone formation and the resulting yellow *hydrazosone*, m.  $162^\circ$ , is accordingly assigned the structure  $\text{O}_2\text{NC}_{10}\text{H}_7\text{CH}(\text{OH})\text{CH}:\text{NNHPh}$ . If the  $\text{NaHSO}_3$  compd. is decompd. with hot  $\text{H}_2\text{SO}_4$ , it yields  $\alpha$ -naphthisatin, m.  $248^\circ$ .  $1,2\text{-C}_{10}\text{H}_7(\text{NO}_2)\text{CH}_2\text{CO}_2\text{H}$  with  $\text{FeSO}_4\cdot\text{NH}_4\text{OH}$  gives  $\alpha$ -naphthoxindole, m.  $247^\circ$ .

CHAS. A. ROUILLER.

**Synthesis of oxalomonoester- and oxalomonoamide[chloroarylhydrazone] acid chlorides and corresponding cyanohydrazones.** CARL BÜLOW AND RICHARD ENGLER. Univ. Tübingen. *Ber.* 51, 1246-70(1918); cf. *C. A.* 12, 2562.—Assuming the "aliphatic-cyclic" structure for acetoacetic ester and similarly constituted 1,3-diketone and 1,3-ketocarboxylic acid derivs. *o*-tolueneazoacetoacetic ester (*C. A.* 2, 2937) is to be represented by the formula (I). It can be obtained in 280 g. yield from 134 g. of *o*- $\text{MeC}_6\text{H}_4\text{NH}_2$  by the method described in the earlier paper if care is taken to use the most concd. soln. possible of the diazonium salt from the purest  $\text{MeC}_6\text{H}_4\text{NH}_2$  and never to let a "milky turbidity" appear during the coupling. The light yellow (I) m.  $52^\circ$  (given before as  $67^\circ$ ). Short boiling with 1% KOH hydrolyzes it and the pure yellow soln. on cooling deposits the *potassium salt* in long, yellow, silky needles. If (I) is covered with concd.  $\text{HNO}_3$ , the crystals at once change with slight evolution of heat into a greenish orange oil; if, however, it is at once cooled and treated with cold  $\text{H}_2\text{O}$  it becomes viscous and yellow; the tar dissolves in boiling 96% alc. and after several days a *nitro derivative* (a) seps. in needles. The original dil.  $\text{HNO}_3$  mother liquors decanted from the "oil" contain a diazonium salt in relatively large amt., for when coupled in soda soln. with R acid there is formed at once a dye similar to ponceau R which gradually seps. in orange flocks. The decompn. of (I) therefore takes place in 2 or 3 phases: (1) nitration; (2) decompn. into  $\text{MeC}_6\text{H}_4\text{N}_2\text{NO}_2$  and a cyclo-aliphatic part, acetoacetic ester,  $\text{CH}_2\text{C}(\text{OH})\cdot\text{CH}_2\cdot\text{C}(\text{OH})\text{OEt}$ . If the (I) is treated in AcOH with  $\text{HNO}_3$ , the nitration

predominates over the decompn. (a) m.  $135-6^\circ$ ; that it is a deriv. of (I) with a  $\text{NO}_2$  group in the  $\text{C}_6\text{H}_4$  nucleus is shown by the fact that when boiled a few min. with  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$  in AcOH it yields [*nitro-o-tolueneazo*]-3-methylpyrazolone, yellow-orange needles, m.  $223-4^\circ$  (decompn.). When a cooled soln. of 100 g. (I) in 600 cc. alc. is treated, with turbinig, with a vigorous stream of Cl cryst.  $\text{MeC}_6\text{H}_4\text{NHN}:\text{CClCO}_2\text{Et}$  (b) begins to sep. in about 45 min.; when the mixt. becomes too stiff to stir well it is filtered and the filtrate is again treated with Cl in the cold, the process being repeated 2-3 times; the (b) is then dissolved in the least possible amt. of boiling alc. and treated without cooling with a slower stream of Cl; the process is repeated once more and the mixt. set in ice, whereupon *monoethyl oxalyl chloride p-chloro-o-tolylhydrazosone* ("*oxalomonoester-[p-chloro-o-tolylhydrazosone] acid chloride*") (c) is obtained in 60 g. yield, needles from alc. or AcOH, m.  $110^\circ$ , sol. in concd.  $\text{H}_2\text{SO}_4$  with intense yellow color, becoming paler in a few sec. and gradually changing to a dirty, faint, brownish green; if the soln. is poured into ice  $\text{H}_2\text{O}$  after 3.5 hrs., it gives a milky turbidity slowly depositing fine, white needles, m.  $109^\circ$ ; the  $\text{H}_2\text{SO}_4$  soln. heated to about  $100^\circ$  becomes light brown and gives no "milky turbidity" with  $\text{H}_2\text{O}$ ;  $\text{FeCl}_3$  gives no characteristic reaction in either acid or alk. soln. If (c) is covered with concd.  $\text{HNO}_3$ , the crystals first become intensely yellow, then slowly change into a brown oil floating on the  $\text{HNO}_3$  which becomes red-brown; after diin. with  $\text{H}_2\text{O}$  and extn. with  $\text{Et}_2\text{O}$ , relatively much diazonium salt remains in the acid. This "oxidative cleavage" is lessened, as compared with the simple nitration, if the (c) is first dissolved in AcOH before being treated with  $\text{HNO}_3$ . When 5 g. (c) in 60 cc. hot alc. is treated with 7.4 g. KCN in 4 cc. cold  $\text{H}_2\text{O}$ , allowed to stand 15 min. and cooled with ice, there is obtained 3.8 g. of the corresponding *cyanide*,  $\text{ClMeC}_6\text{H}_4\text{NHN}:$

$C(CN)CO_2Et$ , golden yellow needles from alc., m.  $163.5^\circ$ , sol. in warm, very dil. alkalis with pure yellow color and repptd. by  $CO_2$ , sol. in concd.  $H_2SO_4$ , also with pure yellow color and repptd. unchanged by  $H_2O$ . In concd.  $HNO_3$  at  $40-50^\circ$  it dissolves with reddish yellow color and on cooling a *nitro derivative*, m.  $121-2^\circ$ , seps. while the dild. and filtered soln. contains relatively much diazonium salt. With Zn dust and HCl in boiling alc., (c) gives  $4,2-ClMeC_6H_4NH_2$ . A *labile form* of the above cyanide, m.  $106.5^\circ$  and passing into the stable form m.  $163.5^\circ$ , is obtained in 4.1 g. yield by treating 3 g.  $4,2-ClMeC_6H_4NH_2.HCl$  in 17 cc. concd. HCl with acidified  $NaNO_2$  (the temp. can be allowed to rise to  $20^\circ$ ) and very slowly running the clear soln. into 1.9 g.  $NCCH_2CO_2Et$  and 30.7 g. crystd.  $NaOAc$  in 137 cc. alc. It is also easily converted into the stable form by boiling 0.5 hr. in  $AcOH$ . *o-Tolueneazoacetoacetamide*, obtained in 6.8 g. yield by shaking 15 g. (I) with 25 cc. of 96% alc. and 60 cc. aq.  $NH_4OH$ , letting stand 8 days, adding 25, 25 and 50 cc. alc. after 2, 4 and 6 days, resp., and fractionally crystg. from abs. alc. (which gives a very small amt. of the very difficultly sol. *ammonium salt*, m.  $202^\circ$  (decompn.), yielding, on crystn. from concd.  $AcOH$ , the free *acid* in long, greenish yellow needles, m.  $137-8^\circ$ ), seps. in broad, golden yellow needles which dissolve in concd.  $HNO_3$  at  $45^\circ$  with greenish yellow color, the soln. on cooling depositing the *nitro derivative*, m.  $243-4^\circ$ ; only a little diazonium salt is present in the  $HNO_3$ , whereas it is the main product when the amide is treated in alc. suspension with Cl. *p-Tolueneazoacetoacetic ester* (d), obtained in 95% yield like (I), m.  $73-4^\circ$ ; if kept 3.5 hrs. at  $79-80^\circ$  and then allowed to solidify it now m.  $75-7^\circ$  and if heated to  $130^\circ$  its m. p. becomes quite indefinite ( $64-77^\circ$ ). Towards 1-2%  $KOH$ , 'concd.  $HNO_3$ ,  $AcOH-HNO_3$ , it behaves like (I); the *nitro derivative* m.  $143-4^\circ$ , and with  $N_3H_4$  in  $AcOH$

gives 3-methyl-4-[*nitro-p-tolueneazo*]pyrazolone, m.  $234^\circ$ . *Monoethyl oxalyl chloride 2-chloro-4-methylphenylhydrazone* (e), obtained like (c) in 60% yield, m.  $100^\circ$ , can be boiled with  $H_2O$  a long time without change, gives a diazonium salt with concd.  $HNO_3$ . *Monoethyl oxalyl chloride 4-methylphenylhydrazone*, obtained in 2.6 g. yield by passing Cl (180-200 bubbles per min.) into 5 g. (d) in 50 cc. cold  $CCl_4$  until the increase in wt. is 0.7-0.8 g., letting stand 1 day, during which time much HCl is evolved, and allowing to evap. in shallow dishes, long, felted needles from alc., m.  $101-1.5^\circ$ , sol. in concd.  $H_2SO_4$  without change, with yellow color, but if allowed to stand in the acid soln. it undergoes deep-seated decompn., behaves towards concd.  $HNO_3$  like (e), converted by alkalis into ditolyltetrazinedicarboxylic ester. *Monoethyl oxalonitrile 2-chloro-4-methylphenylhydrazone*, obtained in 65% yield, golden yellow needles from  $AcOH$ , m.  $160^\circ$ , sol. slowly in concd.  $H_2SO_4$  with yellow color, both nitrated and decompd. by  $HNO_3$ , the resulting diazonium salt giving a ponceau-red dye with R acid, sol. in alkali with yellow color and repptd. by  $CO_2$  in a *labile form*, cryst. flocks. Treated with Cl in alc. suspension (the temp. can be allowed to rise to  $40^\circ$ ) it deposits white crystals, the filtrate from which contains considerable  $2,4-ClMeC_6H_4N_2Cl$ , which with  $\alpha-C_{10}H_7NH_2$  gives a compd. sol. in alc. HCl with fuchsin-red color changing to brown-yellow on addition of  $NaOAc$ , with  $\beta$ -naphthol dark red needles, m.  $171-2^\circ$ , with  $m-C_6H_4(OH)_2$  a yellow-brown compd. changing to brown-yellow with excess of  $AcOH$ , and with R salt a red dye of the ponceau series. The "white crystals" are the  $NH_4$  salt of the acid corresponding to the nitrile. With Zn dust and alc. HCl (e) gives  $2,4-ClMeC_6H_4NH_2$ . The nitrile is also obtained in 5 g. yield from 3 g.  $2,4-ClMeC_6H_4NH_2$  and  $NCCH_2CO_2Et$ . *p-Tolueneazoacetoacetamide*, obtained in 85% yield, light green leaflets from alc., m.  $173^\circ$ , gives with  $HNO_3$ , together with a little diazonium salt, chiefly the *o*(?)-*nitro de-*

ivative, m.  $211-2^{\circ}$ , which with  $N_2H_4$  yields a pyrazolone m.  $235-5.5^{\circ}$ ; as intermediate product is formed a yellow hydrazone (II). The amide (2 g.) treated in 60 cc. boiling alc. with Cl gives 1.5 g. oxalomonoamide chloride 2-chloro-4-methylphenylhydrazone, microneedles from alc., gives a little diazonium salt with  $HNO_3$ , dissolves in  $H_2SO_4$  with yellow color, in  $C_6H_5N$  without color, but the soln. soon becomes pink and on warming deep brown-yellow; if the soln. is now dild. and acidified a yellow powder slowly seps. (tetrazine formation); the HCl salt with KCN gives the amide cyanide.

New isomerisms in the isatin series. II. GUSTAV HELLER. Univ. Leipzig. Ber. 51, 1270-81(1918); cf. C. A. 12, 2552.—Further investigation has cleared up the relationship between the four isomeric forms of 2,4-dimethylisatin (a). The form designated (I) and already considered as a lactam form corresponds in all respects with the isatin proved to be a lactam and therefore has the structure (A); it gives the indophenin reaction, shows the color change in the alk. soln., gives Na and Ag salts entirely similar to those of isatin and with aq.  $PhNHNH_2$  soon forms a yellow phenylhydrazone. Of the isomer (II), which also gives the indophenin reaction, the supposed O-Ag salt (from the Na salt and  $AgNO_3$ ) has been found to deflagrate on heating and to contain much more Ag than the amt. calcd. for a simple Ag salt. The N-Ag salt (from (A) in alc. with  $AgOAc$ ) gives with MeI in  $C_6H_6$  after 2.5 hrs. at  $100^{\circ}$  the Me ether, m.  $232^{\circ}$  (the m. p. formerly given was erroneous) of (I), which therefore has the structure (B), and as (II) is formed from (A) (from the Ag salt and  $BzCl$ ), has the same compn., is monomol., gives the indophenin reaction and yields (B) on short warming with undild.  $Me_2SO_4$ , it has the lactim structure corresponding to (B). That the Me ether really has the structure (B) is shown by the fact that when finely ground and heated some hrs. on the  $H_2O$  bath with dil. NaOH it dissolves and on acidification yields (A). Boiled 3 hrs. in  $AcOH$ , it is likewise largely converted into (A); there is also formed a small amt. of alk.-insol. substance which, however, is not identical with the N-ether. The salts of (a) always regenerate pure homogeneous (A) and are therefore N-salts; in

general there is no evidence that the lactim can form salts of its own; its  $C_6H_6$  soln. does not change color on addition of alc.  $NH_3$  and on concn. deposits the unchanged lactim; the red  $C_6H_5N$  soln., however, at once assumes a bluish red color with  $Ba(OH)_2$ . Since isatol can be converted back into isatin, gives no indophenin reaction and shows no color change with alkalis, it can have only the structure (C) or (D), and the violet to blue salts of  $\alpha$ -isatin derivs. must therefore also be N-salts. Likewise isatin dianil, in which there is no possibility of rearrangement, gives a blue N-salt; the yellow alc. soln. becomes intensely blue with  $NaOEt$  or alc. NaOH, even in the cold. These results establish the analogy between (a) and isatin. As already reported, the lactim when dissolved in alkali rearranges into the isomer (III), which has isatol properties and on more vigorous treatment with alkali is converted into (A). The lactim is apparently a pseudo acid of the isatol only, because it is not regenerated from the isatol. If the reaction between the Ag salt of (A) and  $BzCl$  is carried out in pure thiophene-free  $C_6H_6$  protected from atm. moisture the amt. of regenerated (A) is much diminished and practically only the lactim is formed. Ag isatin in thiophene-free  $C_6H_6$  gives chiefly isatol and as the process in other respects proceeds in the same manner as in the case of (A) it is probable that here too the lactim is first formed. In the action of alkalis on isatin

O-Me ether no isatol was obtained but as the latter also forms isatinic acid with alkalis, though not so rapidly, its formation as an intermediate product is not excluded and the process is probably as follows: Me ether  $\rightarrow$  lactim  $\rightarrow$  isatol  $\rightarrow$  isatinate. Also, as the salts of isatin are *N*-salts, a smooth conversion of the lactim into the lactam in alk. soln. has not yet been established. That it does not take place is rendered probable by the behavior of the lactim form of (a) which in alk. soln. smoothly forms the isatol. In acids the conversion lactim  $\rightarrow$  lactam has been established. Isatin chloride also with Zn dust and AcOH smoothly gives indigo and the mother liquors yield a little isatin, probably formed from the intermediate lactim, but in alkali there is no such smooth regeneration of isatin; if the chloride is allowed to stand in alkali it dissolves in a few hrs. with brown color, leaving indigo-like dyes undissolved; the alk. soln. on acidification yields dark flocks possibly containing isatole and the acid filtrate on long standing deposits some isatin. As to the tautomerism between lactim and isatol it has been found, in the cases thus far studied, to be homogeneous, represented in 1 direction by the smooth rearrangement of the lactim of (a) into the isatol and in the other by heating the isatol with 50% AcOH; unlike other solvents, which give a yellow color, this gives a red soln. due to immediate rearrangement; if sufficiently concd. the soln. even while still hot deposits (B). Likewise the Me ether of the isatol gives quite rapidly the green indophenin reaction of (B). In the absence of acids the tautomerism phenomenon does not appear; the Na salt of the isatol gives with MeI the same isatol ether as the Ag salt. As to isomer (IV), obtained by recrystg. the isatol from AcOH in red needles, sintering above 285°, m. 315° (decompn.), it apparently contains another ring system insol. in alkalies and showing basic properties. Its Me ether on short heating with 50% AcOH is hydrolyzed back to the original substance. 2,4,5-Trimethylisatin can also be obtained by slowly treating the oxindole compd. in 10 parts AcOH at about 50° with  $\frac{1}{8}$  part  $\text{CrO}_3$  in a little  $\text{H}_2\text{O}$ ; its finely divided paste with very dil. alkali dissolves in the cold with dark red color but in more concd. alkali it dissolves with difficulty even on warming, as the salt is insol. in excess of alkali. The Ag salt, granules from  $\text{C}_6\text{H}_6$ , slowly m. from 250° up, is prepd. from 9.5 g. of the isatin in 850 cc. alc. and 8.5 g.  $\text{AgOAc}$  in 900 cc.  $\text{H}_2\text{O}$ ; 9 g. heated 2 hrs. on the  $\text{H}_2\text{O}$  bath with 4.2 g.  $\text{BzCl}$  in 90 cc.  $\text{C}_6\text{H}_6$ , gives, besides the unchanged isatin, *trimethylisatol*, granules from the very concd. mother liquors, does not react with alc.  $\text{PhNHNH}_3$ , sol. in cold dil. soda and in  $\text{NH}_4\text{OH}$  with blood-red color; the soln. in dil.  $\text{NaOH}$  is decolorized on boiling 1-2 min. and acids ppt. the isatin. The isatolseps. from AcOH in fine, dark red needles, m. 229-30°, which are insol. in alkali and are therefore a rearrangement product.

CHAS. A. ROUILLER.

Nucleus halogen-substituted silicon hydrocarbons and their use in syntheses. GERHARD GRÜTTNER AND MARIANNE CAUER. Techn. Hochschule, Berlin. *Ber.* 51, 1283-92 (1918); cf. *C. A.* 12, 1388.—The following *p*-bromophenylsilylic esters,  $\text{BrC}_6\text{H}_4\text{-Si(OR)}_3$ , were prepd. by slowly adding 20 g.  $\text{BrC}_6\text{H}_4\text{SiCl}_3$  to about 3 times the calcd. amt. of the cold alc., distg. off the excess of alc. under atm. pressure and fractionating the residue *in vacuo*; yield, 50%, together with considerable amts. of much higher boiling substances; they are colorless liquids of pleasant odor, rapidly decompd. by  $\text{H}_2\text{O}$ , reacting rapidly in  $\text{Et}_2\text{O}$  with etched Mg: *methyl*,  $b_{11.5}$  136°,  $d_4^{20}$  1.3525,  $d_4^{20}$  1.3493,  $n$  1.50791,  $n$  1.51210, 1.52296 for  $\text{H}_\alpha$ , D and  $\text{H}_\beta$  at 16.5°. *Ethyl*,  $b_{12}$  149-50°,  $d_4^{16.6}$  1.2276,  $d_4^{20}$  1.2244,  $n$  1.48872, 1.49247, 1.50206 at 15.4°; *propyl*,  $b_{14}$  175-6°,  $d_4^{18.6}$  1.1564,  $d_4^{20}$  1.1553,  $n$  1.48144, 1.48497, 1.49386, 1.50129 for  $\text{H}_\alpha$ , D,  $\text{H}_\beta$  and  $\text{H}_\gamma$  at 16.6°; *isobutyl*,  $b_{14}$  190-1°,  $d_4^{17.2}$  1.0949,  $d_4^{20}$  1.0923,  $n$  1.47531, 1.47865, 1.48698, 1.49424, at 14.9°. The following *p*-triethylsilylphenyl alcohols were obtained by slowly adding twice the calcd. amt. of aldehyde to the Mg compd. from 0.1 mol. *p*- $\text{BrC}_6\text{H}_4\text{SiEt}_3$  in 100 g.  $\text{Et}_2\text{O}$ , boiling 4 hrs., decompg. with  $\text{H}_2\text{O}$  and dil.  $\text{H}_2\text{SO}_4$ , drying

the  $\text{Et}_2\text{O}$  layer with  $\text{Na}_2\text{SO}_4$  and fractionating *in vacuo*. Only the first is obtained in good yield; all are thick, colorless liquids of pleasant odor, insol. in  $\text{H}_2\text{O}$ . *Ethanol*,  $\text{Et}_3\text{SiC}_6\text{H}_4\text{CH}(\text{OH})\text{Me}$ ,  $b_{14.5}$  173–4°,  $d_4^{19.5}$  0.9601,  $d_4^{20}$  0.9596,  $n$  1.51404, 1.51822, 1.52885, 1.55810 at 17.2°,  $dn/dt$  –0.00042, –0.00042, 0.00043 for  $\text{H}_\alpha$ , D and  $\text{H}_\beta$ ; *propanol*,  $b_{18.5}$  185°,  $d_4^{17.0}$  0.9663,  $d_4^{20}$  0.9575,  $n$  1.51243, 1.51661, 1.52734 for  $\text{H}_\alpha$ , D and  $\text{H}_\beta$  at 18°; *butanol*,  $b_{21}$  199–201°,  $d_4^{14}$  0.9546,  $d_4^{20}$  0.9491,  $n$  1.50373, 1.50754, 1.51737; *isobutanol*,  $b_{18}$  190–2°,  $d_4^{15.6}$  0.9535,  $d_4^{20}$  0.9512,  $n$  1.50820, 1.51212, 1.52231 at 19.2°,  $dn/dt$  –0.00042, –0.00043, –0.00044 for  $\text{H}_\alpha$ , D and  $\text{H}_\beta$ . *Triethylsilicol*,  $\text{Et}_3\text{SiOH}$ , obtained in good yield by heating the ethanol with fuming  $\text{HCl}$  in a sealed, tube at 90°,  $b_{14.5}$  70.5°,  $d_4^{19.7}$  0.8650,  $d_4^{20}$  0.8647,  $n$  1.43393, 1.43639, 1.44228, 1.44675  $dn/dt$  –0.00042, –0.00043, –0.00044. *p-Triethylsilylphenylsilicon trichloride*, obtained in 39 g. yield from 117 g.  $p\text{-BrC}_6\text{H}_4\text{SiEt}_3$  and 12 g.  $\text{Mg}$  in 200 cc.  $\text{Et}_2\text{O}$  added to 100 g.  $\text{SiCl}_4$  in  $\text{Et}_2\text{O}$ , strongly refractive oil of penetrating odor,  $b_{14.5}$  173–6°, fumes in the air and is immediately hydrolyzed by  $\text{H}_2\text{O}$ ; 40 g. boiled 2 hrs. with 97 g.  $\text{EtBr}$  and  $\text{Mg}$  in 250 cc.  $\text{Et}_2\text{O}$  gives 15.5 g. of *bis-p-triethylsilylbenzene*, rather mobile oil of faint, not unpleasant odor,  $b_{14.5}$  195–6°,  $d_4^{17.6}$  0.8989,  $d_4^{20}$  0.8967,  $n$  1.50555, 1.50942, 1.51945, 1.52788 at 15.7°,  $dn/dt$  –0.00043, –0.00041, –0.00043, –0.00042. Treated very slowly with 4 atoms  $\text{Br}$  and a little  $\text{Fe}$  filings, it gives  $p\text{-C}_6\text{H}_4\text{Br}_2$  and  $\text{Et}_3\text{SiBr}$ ,  $b_{14}$  66.5°, loses  $\text{HBr}$  abundantly in moist air, at once hydrolyzed by  $\text{H}_2\text{O}$ ,  $d_4^{20}$  1.1766,  $n$  1.46402, 1.46705, 1.47447, 1.48074 at 15.7°. *Phenyl-p-bromophenylsilicon dichloride*, from  $\text{PhSiCl}_2$  boiled 5 hrs. in  $\text{Et}_2\text{O}$  with  $p\text{-C}_6\text{H}_4\text{Br}_2$  and  $\text{Mg}$ , oil fuming in the air,  $b_{14}$  199–200°,  $d_4^{18.5}$  1.5019,  $d_4^{20}$  1.5005,  $n$  1.60294, 1.60921, 1.62531, 1.63953 at 19°. *Diethoxyphenyl-p-bromophenylsilane*,  $\text{Ph}(\text{BrC}_6\text{H}_4)\text{Si}(\text{OEt})_2$ ,  $b_{17}$  201°,  $d_4^{21.6}$  1.2474,  $d_4^{20}$  1.2488,  $n$  1.54525, 1.55031, 1.56322, 1.57467 at 19°, is obtained from  $\text{Ph}(\text{BrC}_6\text{H}_4)\text{-SiCl}_2$  and excess of  $\text{EtOH}$ ; at the same time is formed a compd.  $b_{30}$  317–8°,  $d_4^{22}$  1.3350,  $d_4^{20}$  1.3369,  $n$  1.57867, 1.58437, 1.59895, 1.61146 at 18.6°, mol. wt. in freezing  $\text{C}_6\text{H}_6$  550, which is apparently *bis[ethoxyphenyl-p-bromophenyl]disiloxan*,  $[\text{Ph}(\text{BrC}_6\text{H}_4)(\text{EtO})_2\text{-Si}]_2\text{O}$ .  $\text{EtMgBr}$  and  $\text{Ph}(\text{BrC}_6\text{H}_4)\text{SiCl}_2$  boiled several hrs. in  $\text{Et}_2\text{O}$  give *diethylphenyl-p-bromophenylsilane*,  $b_{14.5}$  203–3.5°,  $d_4^{19.7}$  1.2156,  $d_4^{20}$  1.2153,  $n$  1.57794, 1.58351, 1.59781, 1.61035 at 17.9°, and *diethylphenyl-p-ethylphenylsilane*,  $b_{14}$  169–70°,  $d_4^{19}$  0.98403,  $d_4^{20}$  0.98310,  $n$  1.55716, 1.56225, 1.57559, 1.58713. *Triethyl-p-ethylphenylsilane*, from  $\text{EtMgBr}$  and  $\text{BrC}_6\text{H}_4\text{SiCl}_2$ ,  $b_{18}$  117–8°,  $d_4^{18.2}$  0.8969,  $d_4^{20}$  0.8950,  $n$  1.50272, 1.50671, 1.51697, 1.52583 at 20.7°. All the values for  $d$ . given above are reduced to vacuum.

CHAS. A. ROUILLER.

**Organic lead compounds. VIII. Mixed lead alkyl aryls of the type  $\text{Alk}_3\text{PbAr}$ .** GERHARD GRÜTTNER and GERTRUD GRÜTTNER. Techn. Hochschule, Berlin. *Ber.* 51, 1293–8(1918).—These compds. are prepd. according to the scheme  $\text{Alk}_3\text{PbX} + \text{ArMgX} = \text{Alk}_3\text{PbAr} + \text{MgX}_2$ . Diaryls are always formed to some extent, and as their  $b$ . ps. are higher than those of the trimethyl- but lower than those of the triethylead aryls, sepn. can be effected in all cases by fractional distn. or, if the diaryls cryst., by freezing out, as the alkylaryls do not solidify even at low temps. The compds. are colorless, strongly refractive oils of faint odor, distil *in vacuo* in a  $\text{CO}_2$  atm. without decompn. ( $\text{Et}_3\text{PbCH}_2\text{Ph}$  splits off a little  $(\text{PhCH}_2)_2$ ) while in air a small amt. of a yellow-brown ppt. is sometimes formed. With steam the tri-Me derivs. are easily, the tri-Et compds. rather difficultly volatile; when pure they are stable for months even in air and diffuse light; heated above 200°, they deposit  $\text{Pb}$ ; when ignited they burn with a reddish flame and formation of a cloud of  $\text{PbO}$ . With  $\text{Br}$  in  $\text{Et}_2\text{O}$  at –75° they split off the aryl and sometimes one of the alkyls to a slight extent. The crude products were all prepd. by boiling 0.2 mol.  $\text{Alk}_3\text{PbBr}$  with 0.3 mol.  $\text{ArMgBr}$  1 hr. in  $\text{Et}_2\text{O}$ ; the method of purification differed for each. *Trimethylphenyllead* (yield, 66%),  $b_{18}$  104°,  $d_4^{23.7}$  1.7342,  $d_4^{20}$  1.7376,  $n$  1.5753, 1.5816, 1.5988, 1.6138 for  $\text{H}_\alpha$ , D,  $\text{H}_\beta$  and  $\text{H}_\gamma$  at 23.7°.

*Trimethyl-p-tolyllead* (yield, 34%),  $b_{11}$  118–9°,  $d_4^{20}$  1.6826,  $d_4^{21.6}$  1.6812,  $n$  1.5672, 1.5732, 1.5895, 1.6039 at 20°. *o-Isomer* (yield, 48%),  $b_{11}$  117.5–8.0°,  $d_4^{21.4}$  1.7395,  $d_4^{20}$  1.7408,  $n$  1.5734, 1.5793, 1.5954, 1.6095 at 21.4°. *Triethylphenyllead* (yield, 61%),  $b_{11}$  135°,  $d_4^{21.1}$  1.5920,  $d_4^{20}$  1.5931,  $n$  1.5698, 1.5757, 1.5917, 1.6057 at 21.1°. *p-Tolyl homolog* (yield, 78%),  $b_{11}$  154°,  $d_4^{24.8}$  1.5237,  $d_4^{22}$  1.5262,  $d_4^{20}$  1.5281,  $n$  1.5629, 1.5686, 1.5842, 1.5979 at 22°. *o-Isomer*,  $b_{11}$  153.5°,  $d_4^{22.2}$  1.5832,  $d_4^{21.6}$  1.5839,  $d_4^{20}$  1.5853,  $n$  1.5682, 1.5740, 1.5897, 1.6035 at 21.5°. *Benzyl isomer*,  $b_{11}$  149–50.5°,  $d_4^{23}$  1.5374,  $n_D^{21.4}$  1.5843, deposits  $(PhCH_2)_2$  after each distn. *Triethyl- $\alpha$ -naphthyllead*,  $b_{11}$  176° (loss of  $C_{10}H_8$ ). *Trimethylbenzyllead*,  $b_{11}$  124° (decompn.). IX. *Triphenyllead monohalides*. GERHARD GRÜTTNER. *Ibid* 1298–303.—When  $Ph_4Pb$  is treated slowly with 2 mols.  $Br_2$  in  $Et_2O$  at  $-75^\circ$  (solid  $CO_2$ ) or in melting  $CS_2$ , the color disappears quite rapidly and the product consists chiefly of unchanged  $Ph_4Pb$  and  $Ph_3PbBr$ , with only about 10% of  $Ph_3PbBr$ ; this is probably due to the fact that the insol.  $Ph_4Pb$ , even though very finely divided, offers but a relatively small surface of attack to the  $Br$ , while the sol.  $Ph_3PbBr$  first formed reacts very much more rapidly. By using a suspension of  $Ph_4Pb$  in  $C_4H_9N$  and a soln. of  $Br$  in  $C_4H_9N$  at above  $-40^\circ$ , however,  $Ph_3PbBr$  is obtained almost quant. Triphenyllead bromide seps. from alc. in silky needles, sinters  $164^\circ$ , m.  $166^\circ$  to a clear liquid gradually depositing  $PbBr_2$ , deflagrates with reddish light and deposition of  $Pb$  when heated rapidly, causes sneezing when dry. *Iodide*, best obtained by treating each l. of the alc. mother liquors from the bromide with 40 g.  $KI$  in 100 g.  $H_2O$  and then with  $H_2O$  until the resulting turbidity only slowly redissolves, pale yellow, flat prisms, sinters  $139^\circ$ , m.  $142^\circ$ . *Oxide*, best obtained in small amts. by adding an excess of alc.  $NaOH$  or  $KOH$  to a hot alc. soln. of the bromide and pouring into 2 vols. cold, slightly alk.  $H_2O$ , forms a flocculent ppt. insol. in aq. but sol. in alc. alkalies. Large amts. are better prepd. by shaking a paste of the bromide and a little  $Et_2O$  for 2 hrs. with excess of 10% aq. alkali. *Chloride*, obtained quant. by shaking the oxide a short time with 15%  $HCl$ , needles or flat prisms from alc., sinters  $204^\circ$ , m.  $206^\circ$ . *Sulfide*, obtained as a white ppt. by passing  $H_2S$  into a concd. alc. soln. of the chloride, is remarkably sol. in organic solvents when freshly pptd. and quite stable towards heat.

CHAS. A. ROUILLER.

**The monohydrochloride of isoprene.** OSSIAN ASCHAN. Univ. Helsingfors. *Ber.* 51, 1303–7 (1918); cf. Bouchardt, *Jahresb.* 1879, 577.—The isoprene used had been prepd. from pure com. carvene by means of a Harries and Gottlob isoprene lamp (*C. A.* 5, 3583) and had stood 4 years in an ice chest at  $4-8^\circ$ . It contained considerable caoutchouc; 654 g. on steam distn. yielded 590 g. distillate and 36 g. white, spongy caoutchouc. Into 50 g. of the fraction of the distillate which b.  $34-5.5^\circ$ ,  $d_4^{20}$  0.6765, and 3 g.  $H_2O$ , cooled with snow- $NaCl$ , dry  $HCl$  was passed for several hrs.; the increase in wt. was 29 g. After washing with  $H_2O$ , drying with a little  $KOH$  and again satg. with  $HCl$  the portion of the product which distd. below  $90^\circ$ , there were obtained 22.6 g. b.  $107-10^\circ$  (constant at  $109^\circ$ ),  $d_4^{20}$  0.9335, with 33.99%  $Cl$  (calcd. for isoprene- $HCl$ , 33.97), and a fraction b.  $87-90^\circ$ , d. 0.8702, with 33.59%  $Cl$  (calcd. for amylene- $HCl$ , 33.33%). Therefore, contrary to B., the fraction b. below  $90^\circ$  is  $Me_3CClEt$ ; a sample prepd. from pure  $Me_3C:CHMe$  b.  $85-8^\circ$  and showed d. 0.8709. The presence of  $Me_3C:CHMe$  in the isoprene used was shown by means of the reaction with anhydrous  $AlCl_3$  (formation, with gas evolution, of a solid condensation product). The true isoprene hydrochloride smells like allyl chloride, decolorizes alk.  $KMnO_4$ , adds  $HCl$  and  $Br$ , darkens on standing, tends to lose a little  $HCl$  on distn., loses  $Cl$  and probably forms an alc. when boiled with  $K_2CO_3$  while heating in glacial  $AcOH$  with  $NaOAc$  to a large extent regenerates isoprene. Satd. in concd.  $HCl$  with  $HCl$  gas, it gives 94% of the dihydrochloride,  $b_{11}$   $52-3^\circ$ , b.  $145-6^\circ$ ,  $d_4^{20}$  1.0654; with  $Br$  in cold  $CHCl_3$  it forms the dibromide, a thick, yellowish oil. In the above expts. no condensation

to a caoutchouc-like substance was ever observed, as B. claims to be the case when HCl acts on isoprene.

CHAS. A. ROULLER.

**Synthesis of optically active glycerylphosphoric acid.** EMIL ABDERHALDEN AND EGON EICHWALD. *Ber.* 51, 1308-12 (1918).—To 14 g. *d*-bromohydrin,  $[\alpha]_D^{18}$  4.38°, in 100 g. anhydrous  $C_6H_5N$  in ice-NaCl 14 g.  $POCl_3$  are very slowly added in 10-5 drop portions, keeping the temp. below  $-10^\circ$ ; after 1-2 hrs. 300 cc. ice-cold  $H_2O$  are slowly added and the soln. is shaken with about 40 g.  $Ag_2SO_4$  (if this is not enough, more  $Ag_2SO_4$  is added in 1 g. portions until the filtrate no longer gives a reaction for Cl ions).  $H_2S$  is passed into the filtrate, the filtered soln. concd. somewhat *in vacuo*, made strongly alk. with  $Ba(OH)_2$ , dild. to 0.5 l., again concd. *in vacuo* to about 200 cc., filtered through a little charcoal, freed exactly of Ba with  $H_2SO_4$ , made alk. to phenolphthalein with 10% LiOH, then treated with 1.5 times as much more LiOH, allowed to stand 24 hrs., concd. *in vacuo* to about 150 cc., heated 1 hr. at  $80^\circ$ , cooled, neutralized to phenolphthalein with HBr, treated with a little charcoal if dark, concd. *in vacuo* to incipient sepn. of salts (which are redissolved with a few cc. of  $H_2O$ ), filtered, pptd. with 200 cc. abs. alc., dissolved in a little  $H_2O$ , again pptd. with alc., then again pptd. a 3rd time and dried at  $100^\circ$  *in vacuo* over  $P_2O_5$ . In spite of many attempts, the *dilithium d*-glycerylphosphate so obtained generally did not have exactly the compn.  $C_6H_7O_6PLi_2$ ; some samples had almost exactly the calcd. amt. of  $P_2O_5$  (38.74 instead of 38.59%), but in general the P content was too low and the C too high. Perhaps small amts. of diglycerylphosphate were formed. Yield, 3.5 g. The *d*-salt shows  $[\alpha]_D^{18}$  3.51°, the *l*-salt  $-3.02^\circ$ . A sample obtained with alc. instead of aq. LiOH showed  $[\alpha]_D^{18}$  6.26°.

CHAS. A. ROULLER.

**Optically active propyleneglycol and optically active  $\beta$ -hydroxybutyric acid.** EMIL ABDERHALDEN AND EGON EICHWALD. Univ. Halle a. S. *Ber.* 51, 1312-22 (1918); cf. *C. A.* 10, 464.—One kg.  $CH_2:CHCH_2NCS$  is hydrolyzed with 1.25 kg. of 20% HCl almost completely; the remainder of the oil distd. off *in vacuo*, the soln. of  $CH_2:CHCH_2NH_2 \cdot HCl$  concd. to about 800 cc., satd. at  $0^\circ$  with HCl gas, heated 5-6 hrs. at  $110-20^\circ$ , concd. as far as possible in a porcelain dish, allowed to stand 24 hrs. at room temp., filtered and the filtrate again satd. with HCl and heated in sealed tubes. The still moist *dl*- $MeCHClCH_2NH_2 \cdot HCl$  so obtained is treated in a little  $H_2O$  and ice under  $Et_2O$  with an excess of 33% KOH in small portions, shaking vigorously after each addition, removing the  $Et_2O$  layer before quite the calcd. amt. of KOH has been added, then adding the rest of the KOH and extg. repeatedly with  $Et_2O$ . The  $Et_2O$  soln. is concd. to about 300 cc. (some of the amine also distils over) and treated with an equal vol. of alc.; the amt. of amine is detd. by titration of an aliquot portion with alizarin-sulfonic acid as indicator and to the main soln. is added 1 mol. *d*-tartaric acid in  $H_2O$  to each mol. amine; soon *d*- $\beta$ -chloropropylamine tartrate (*a*) seps.; the rest of the  $Et_2O$  is now evapd. off and the (*a*) crystd. about 10 times from  $H_2O$ ; it m.  $109.5^\circ$  and shows  $[\alpha]_D^{18}$  36.72° (max. value observed). The base liberated from (*a*) by treatment with alkali and extn. with  $Et_2O$  yields with alc. HCl a *hydrochloride*, m.  $179.5^\circ$ , with  $[\alpha]_D^{18}$  34.80°. The *l*-hydrochloride obtained from the mother liquors shows  $[\alpha]_D^{18}$   $-17.07^\circ$ . To 200 g. (*a*) in not too much  $H_2O$  at about  $10^\circ$  is slowly added 100 g.  $NaNO_2$  in  $H_2O$ , the soln. (from which much salt has sepd.) is extd. 5-6 times with  $Et_2O$  and the ext. is dried with  $Na_2SO_4$  and fractionated, yielding 40 g. *d*-chloro- $\alpha$ -propanol (*b*) (despite repeated distns. the alc. cannot be obtained quite pure; the Cl content is always too low), b.p.  $40-1^\circ$ , d. 1.1122,  $[\alpha]_D^{18}$  9.26°. The purest *l*-antipode so far obtained showed d. 1.1122,  $[\alpha]_D^{18}$   $-2.92^\circ$ . *dl*- $\beta$ -Bromopropanol was also prepd.; as the tartrate of the amine (except in 1 single case) could not be made to cryst., the use of the Br compds. in the attempt to prep. active derivs. was given up. To 0.5 part KOH in 2 parts  $H_2O$  at about  $50^\circ$  in a distg. flask connected with an iced- $H_2O$  condenser and a receiver in a

freezing mixt. is added, not too slowly, 23 g. (b) and the flask is rapidly heated to 70°; there is thus obtained 10 g. *d*-propylene oxide (c), b. 36.5–8.0°, d. 0.8412,  $[\alpha]_D^{18}$  12.72°. The purest *l*-compound so far obtained showed d. 0.8412,  $[\alpha]_D^{18}$  –8.26°. (c) is added dropwise to cold anhydrous HCO<sub>2</sub>H, allowed to stand 2–3 hrs., freed from excess of HCO<sub>2</sub>H *in vacuo*, treated with 15% HCl, hydrolyzed by allowing to stand 1 hr. at 50° with frequent shaking, concd. *in vacuo* below 40°, treated with H<sub>2</sub>O and concd. repeatedly until all the HCl is removed and fractionated; the *d*-propyleneglycol (d) b<sub>14</sub> 95°,  $[\alpha]_D^{18}$  13.71° (H<sub>2</sub>O); *l*-compound,  $[\alpha]_D^{18}$  –8.97°. On standing in H<sub>2</sub>O or heating with H<sub>2</sub>O, the glycol is extensively racemized, sometimes yielding a weakly *d*-, sometimes a *l*-rotatory product; at present no satisfactory explanation of this can be offered. *d*-Propyleneglycoldibutyryn, from (d) in CHCl<sub>3</sub> and 6 parts PrCOCl at 50°, b<sub>14</sub> 95–105°,  $\alpha$  2.05° in a 1 dcm. tube.  $\beta$ -Bromoisopropyl alcohol (e), from 20 g. (c) slowly added to 30 cc. HBr (d. 1.49) in 80 cc. cold H<sub>2</sub>O and allowed to stand 0.5 hr. (yield, 25 g.), b<sub>14</sub> 45–50°,  $\alpha$  –2.02° in a 1 dcm. tube; the *l*-form of (c) gave an alcohol with  $\alpha$  1.15°. From 5 g. (e) in 20 cc. alc. boiled with 5 g. KCN is obtained 4 g. of  $\beta$ -hydroxybutyronitrile (f), b<sub>14</sub> 99–100°,  $[\alpha]_D^{18}$  –10.03°, while the *d*-rotatory (e) from the *l*-rotatory (c) gave a nitrile with  $[\alpha]_D^{18}$  8.78°. On heating several hrs. on the H<sub>2</sub>O bath with concd. HCl, (f) gives the acid,  $[\alpha]_D^{18}$  –13.28°. From 15.5 g. (b) allowed to stand 24 hrs. with 50 g. (NH<sub>4</sub>)<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> in 48 cc. concd. H<sub>2</sub>SO<sub>4</sub> and 320 cc. H<sub>2</sub>O is obtained an  $\alpha$ -chloropropionic acid with  $\alpha$  –2.25° in a 2 cm. tube; this allowed to stand 14 days with aq. NH<sub>4</sub>OH, then shaken with Ag<sub>2</sub>SO<sub>4</sub>, pptd. with exactly the calcd. amt. of HCl, then with Ba(OH)<sub>2</sub>, evapd. *in vacuo*, and extd. with alc. to remove any MeCH(NH<sub>2</sub>)CH<sub>2</sub>OH, yields a residue (alanine) which in dil. HCl is strongly *l*-rotatory. CHAS. A. ROUILLER.

The freezing points of mixtures of phenol, *o*-, *m*- and *p*-cresol (DAWSON, MOUNTFORD) 7. Aktie Selskabet Karbidindustri (acetic acid and alcohol from calcium carbide) (ANON.) 4. Critical phenomena (FIELDING) 2. The chemistry of sweetening agents (BARRAL, RANC) 12. Some physical constants of "mustard gas" (ADAMS, WILLIAMSON) 2.

**Sulfonic acids.** J. E. SOUTHCORBE and R. M. DOWNIE. Brit. 120,405, Sept. 7, 1917. The mixt. of naphthalenesulfonic acids with H<sub>2</sub>SO<sub>4</sub> obtained by the sulfonation of naphthalene, is worked up by first partially neutralizing the mass with an alkali (Na<sub>2</sub>CO<sub>3</sub> or NaOH) and completing the neutralization by adding CaO; the CaSO<sub>4</sub> is filtered off, any excess of lime is pptd. by Na<sub>2</sub>CO<sub>3</sub>, and the resulting soln. of Na naphthalenesulfonates filtered.

**Derivatives of hydroxyarylquinolinedicarboxylic acids.** FARBW. VORM M. L. & B. Ger. 305,885, addition to 293,467, 1918 (C. A. 11, 2581). Derivs. of isatic acid, substituted in the nucleus, are condensed with acetylsalicylic or acetylcresotic acids. Thus, hydroxytolylquinolinedicarboxylic acid, orange powder, decomp. above 280°, is prepd. by warming 5-methylisatin with *p*-acetylsalicylic acid in the presence of KOH and H<sub>2</sub>O. Similarly, 5,6-methylenedioxyisatin and *p*-acetylsalicylic acid yields a quinolinedicarboxylic acid, yellow powder. The product obtained from *p*-methylisatin and acetyl-*p*-cresotic acid is a yellowish red powder, which decomposes at 290°. 6-Bromo-4'-hydroxyphenylquinoline-4,3'-dicarboxylic acid, yellow powder, decomp. at about 273°, results from 5-bromoisatin and *p*-acetylsalicylic acid.

**Glycolyl-*p*-aminophenyl ethers.** FARBWERKE VORM. M. L. & B. Ger. 306,938, 1918. Glycolyl-*p*-aminophenyl ether is obtained in excellent yield and in a high state of purity by heating *p*-aminophenyl ether with the glycolic anhydrides; the latter are considered to comprize glycolide, m. 86°, polyglycolide, m. 223°, and the product formed when glycolic acid is heated at about 200–250°, which consists of a cryst. pow-

der insol. in  $H_2O$ , by which it is slowly converted into glycolic acid. Esters of glycolic acid can be used in place of the anhydrides. Glycolyl-*p*-phenetidine forms colorless crystals, m.  $153^\circ$ ; glycolyl-*p*-anisidine, m.  $101^\circ$ .

1-Hydroxy- and 1,8-dihydroxyanthranol. BAYER & Co. Ger. 305,886, addition to 296,091, 1918 (cf. C. A. 13, 323). The alkyl ethers of 1-hydroxy- and 1,8-dihydroxyanthraquinones are reduced by Zn in acid soln. in the place of the parent substances. The Me ethers are cited as examples.

Hydrogenated compounds. BAYER & Co. Ger. 306,724, addition to 305,347, 1918 (C. A. 13, 325). Other aromatic isocyclic and heterocyclic compds., in addition to bases, can be reduced with alkali or alk.-earth metals and alc. in the presence of an indifferent solvent. The process is easily regulated and can be stopped at any point by withholding further addition of alc. Thus, tetrahydronaphthalene is obtained from naphthalene, Na, and alc. in the presence of solvent naphtha at  $140-5^\circ$ , and tetrahydridiphenyl, b.  $247-9^\circ$ , b<sub>10</sub>  $115-8^\circ$ , from diphenyl, Na, alc., and solvent naphtha at  $140-50^\circ$ . Acenaphthene yields tetrahydroacenaphthene.

Researches on the microchemistry and the genesis of amyloid. ERNST LEUPOLD. Univ. of Würzburg. *Beitr. path. Anat.* 64, 347-400(1918).—From a review of the literature and from exptl. work which is reported the author makes the following conclusions: Amyloid is a complex of different substances which are differentiated by microchem. reactions. The protein ground substance of the amyloid is refractory to the typical amyloid reactions. The group which is responsible for the methyl-violet reaction is intimately combined with this protein substance and is sepd. from it only by the action of alkali. The groups which give, respectively, the I and the  $I-H_2SO_4$  reactions are closely related to each other. Nevertheless the  $I-H_2SO_4$  reaction is a completely independent one and is not a modification of the I reaction. The occurrence of different colors in the  $I-H_2SO_4$  reaction depends upon different degrees of oxidation. Amyloid is an emulsion colloid in the gel state. After oxidation with  $KMnO_4$  it is sol. in  $NH_4OH$ , NaOH and  $Ba(OH)_2$ . Conjugated  $H_2SO_4$  plays an important part in the production of amyloid in the organism. The existence of large amts. of conjugated  $H_2SO_4$  produces amyloid which gives the  $I-H_2SO_4$  reaction. The methyl-violet reaction also depends on the presence of conjugated  $H_2SO_4$ ; however, for its production there must probably occur a reduction to amyloid protein. The group which gives the  $I-H_2SO_4$  reaction occurs through decompn. and does not depend upon the  $H_2SO_4$ . In chronic suppuration a sol. protein circulates in the blood which is removed by ferments. This protein substance, under certain conditions, is deposited in organs where large amts. of  $H_2SO_4$  occur. For the development of amyloid there are necessary 3 factors, a pre-formed protein, an increased amt. of  $H_2SO_4$ , and an inefficiency of the amyloid-filled organ to eliminate the increased amt. of conjugated  $H_2SO_4$ . JULIAN H. LEWIS.

### C. BACTERIOLOGY.

**Studies on synthetic mediums. I. Study of the characteristics of some bacteria on a simple synthetic.** FLORENCE HULTON-FRANKEL, HELENE BARBER AND ELEANOR PYLE. Columbia Univ., N. Y. *J. Infect. Dis.* 24, 9-16(1919).—The synthetic medium used had the following compn.: 129.5 cc. of  $M$   $H_2PO_4$ , 18 cc. of  $M$   $CH_3COOH$ , 17.8 cc. of  $M$   $NH_4OH$ , 100 cc. of  $M$   $KOH$ , 100 cc. of  $M$   $NaOH$ , 10 cc. of 0.01%  $FeCl_3$ , 10 cc. of 0.01%  $MgSO_4$ , 10 cc. of 0.01%  $CaCl_2$  per l. The H-ion concn. was  $10^{-7}$ . This medium is suitable for the growth of most saprophytic organisms and also for some of the facultative parasitic organisms. None of the characteristics of growth was lost and one property was increased. **II. Sugar fermentation in synthetic medium.** FLORENCE HULTON-FRANKEL AND HELENE BARBER. *Ibid.* 17-8.—To the above synthetic medium dextrose, sucrose, lactose and maltose 1% were added, and the fermentation of these sugars by 60 different organisms was studied. Only 3 of the organisms failed to produce acid or gas when they did so in broth. **III. Some animal experiments with organisms grown on synthetic medium.** FLORENCE HULTON-FRANKEL AND ELEANOR PYLE. *Ibid.* 19-21.—The object of this investigation was to find out if some of the organisms grown on the above synthetic medium had changed in their behavior toward animals. The organisms chosen were *B. mucosus* (Friedlander's bacillus), *Microspira cholerae*, and *B. typhosus* (Hopkins' strain). The first 2 were tried for virulence and the typhoid for the production of antibodies. *B. mucosa* and *B. typhosus* remained unchanged in their effect on animals. However, the synthetic medium lacks something necessary to produce the substance responsible for the pathogenicity of *Microspira cholerae*.

#### D. BOTANY.

CARL L. ALSBERG.

**Chemical correlation in the growth of plants.** W. M. BAYLISS. *Nature* 102, 285-7(1918).—A review of the exptl. work of Loeb on the chem. basis of regeneration and geotropism in plants (*Botan. Gazette* 60, 249(1915); 63, 25(1917); 65, 150(1918); *Science* 66, 115, 547(1917); *Proc. Nat. Acad. Sci.* 4, 117(1918)). The greater growth of the apical buds of plants relative to the lateral buds of the stem is explained on the assumption that when the leaves are first removed, inhibitory substances are present everywhere throughout the stem, but that these have a tendency to flow towards the base. Hence the most apical node is the first one to become freed from their presence, and when its buds grow they form anew the inhibitory substance which prevents the growth of the more basal buds. Evidence is given to show that the inhibitory effect is proportional to the size of the growing apical bud.

W. H. ROSS.

**Physiological studies of normal and blighted spinach. Ash content in normal and in blighted spinach.** R. H. TRUE, O. F. BLACK AND J. W. KELLY. *J. Agr. Research* 15, 371-5(1918).—The total ash of healthy spinach tops is higher than that of blighted plants, while diseased roots have a higher ash content than the normal ones. The proportion of Si present is but little affected by health or disease either in tops or roots. The tops contain several times as much Si as the roots. Ca is localized in the leaves in greater quantity than in the roots in both normal and blighted plants. Mg is higher in both tops and roots in the blighted plants than in the normal ones. The K content is high; normal tops contain 5.93% and the diseased ones 4.08%. Na is found in less amts. than K in the tops, but this is reversed in the roots in some cases. The healthy spinach tops contain an av. of 0.132% Fe, based on dry plant, against 0.095% in the blighted tops. The roots of the diseased plants contain an av. of 0.122% Fe; the normal amt. was 0.065%. It seems that a part of the Fe that entered the plant through the roots accumulated there instead of going up through the leaves as in the normal plants. **Oxidase reaction in healthy and in blighted spinach.** H. H. BUNSELL. *Ibid* 377-80.—The stunting of the plant by disease caused an increased oxidase mechanism. In all but a few instances, there was a difference of 50-100% between the activity of the diseased and of the healthy plant. **Carbohydrate production in healthy and in blighted spinach.** R. H. TRUE AND L. A. HAWKINS. *Ibid* 381-4.—Carbohydrates accumulate in the leaves of plants affected with the spinach-blight in larger quantities than in normal leaves. The starch content of the diseased tops is more than double that of the normal plant. In the roots total sugars and starch are alike in both. It is considered that the cause of the injury "does not affect the machinery of photosynthesis or the materials used in carbohydrate manuf. to such an extent as to stop production. It is indicated that carbohydrate accumulation is due not to a breakdown of digestion but to some partial failure in the subsequent metabolic processes in connection with which carbohydrates are used." **Nitrogen metabolism in normal and in blighted spinach.** S. L. JODIDI, E. H. KELLOGG AND R. H. TRUE. *Ibid* 385-404.—The N content of the healthy plant is higher than in the corresponding diseased tissues, but the N of the diseased roots is higher than of healthy ones. The lower % of total N and of acid amide N in the diseased material can best be explained by the assumption that denitrification takes place in those tissues, whereby part of the N may be lost either as elementary N or in the form of  $\text{NH}_3$ . There is a higher proportion of ammoniacal N in the diseased plant than in the normal, which is probably accounted

for in the process of denitrification, whereby a part of the nitrites is further reduced to  $\text{NH}_3$ . J. J. SKINNER.

The fractional examination of the duodenal contents. MAX EINHORN. *Am. J. Med. Sci.* 156, 817-30(1918).—Examn. of the duodenal contents  $1\frac{1}{2}$  hrs. after a bouillon meal gives the pancreatic juice at the height of its activity. Fasting states give the best results for liver and biliary lesions. Alkalinity is estd. as an index of pancreatic efficiency. Agar tubes were used to det. pancreatic enzyme activity.

W. MORSE.

Glucolysis in the blood. J. HEKMAN AND A. VAN MEETEREN. *Nederlandsch Tijdschrift voor Geneeskunde* 2, 497(1918); *J. Am. Med. Assoc.* 71, 1868.—A micro-method based on the Bang technic is described with which it is possible to est. the sugar-splitting property of the blood. The expts. showed that the glucolysis in the blood is no index of pancreas functioning. The sugar-splitting coeff. is the quotient obtained by dividing the number representing the amt. of sugar in the blood by the number representing the glucolysis. This coeff. varies from 0.7 to 1.5 in normal persons. In diabetes this coeff. may run up to 6 or more.

L. W. RIGGS.

#### G. PATHOLOGY.

H. GIDEON WELLS AND ANDREW HUNTER.

Antibodies in the fetus. HAL W. SHERMAN. John McCormick Inst. for Infect. Dis., Chicago. *J. Infect. Dis.* 24, 1-8(1919).—This paper is a study of the natural antibodies of swine embryos. In the youngest embryo studied the amt. of complement and lysins for various red cells was inappreciable. Opsonins were present but averaged only 0.04 as measured by the opsonic index. Complement and opsonins increase as the age of the fetus increases. Lysins do not appear to increase. In the amniotic fluids complement is only occasionally found; lysins and opsonins resemble closely those of the fetal serums. The conclusion of Polano and Goldmann from their work, respectively, on antitoxins and vital stains, that the amnion has a selective secretory action, seems to be unwarranted. The theory of the transudation of the amniotic fluid from the maternal serum is untenable. The amniotic fluid is probably derived almost exclusively under normal conditions as a transudation from the cord and as a secretion from the surface of the fetus. In the allantoic fluids complement was found only in the younger embryos. Lysins are found more prevalent in the earlier fluids but to a small extent also in the later ones.

JULIAN H. LEWIS.

A comparison of six different antigens in the Wassermann reaction. E. H. RUDRIGER. Bismarck, N. D. *J. Infect. Dis.* 24, 31-44(1919).—Because many different kinds of antigen are being used in the Wassermann reaction 6 different kinds of antigen were subjected to comparative study. The antigens studied were alc. ext. of human heart muscle, alc. ext. of syphilitic fetal liver, alc. ext. of dog heart muscle, alc. ext. of sheep heart muscle and acetone-insol. antigen of sheep heart muscle. Antigen supposed to be alc. ext. of syphilitic fetal liver and antigen prepd. from dog heart gave many more positive results than did alc. ext. of human heart. As no other signs or symptoms of syphilis could be detected these were considered false positive results, and these antigens were discarded as unreliable. Antigen prepd. from sheep heart gave results almost identical with those given by antigen prepd. from human heart. The glycerol added to the human serum cannot be held responsible for the false positive results

obtained. Previous absorption of the natural antidog amboceptor from the human serums did not eliminate the false positive results. Antigen dild. with the salt soln. slowly so as to give an opalescent soln. gave many more positive results with the Wassermann test than did antigen which was dild. rapidly enough to give a clear soln. Adding the antigen to the human serum before the complement gave results identical with those obtained when the complement was added before the antigen. J. H. LEWIS.

**Transmissibility of immunity from mother to offspring in hog cholera.** CLIFFORD L. MCARTHUR. Ark. Expt. Sta. *J. Infect. Dis.* 24, 45-50(1919).—Sows immunized against hog cholera by the Dorset-Niles method transmit this immunity to their offspring. In nearly every case the pigs retained their immunity as long as they were suckling and the sow was immune. When the mother contracted the disease the pigs did not usually survive more than a few days, and in some instances cholera lesions were found on necropsy. These facts seem to indicate that the antibodies are transmitted through the milk during the entire suckling period. JULIAN H. LEWIS.

**Agglutination in measles.** RUTH TUNNICLIFF. (Chicago), Contract Surgeon, U. S. A. *J. Infect. Dis.* 24, 76-7(1919).—Expts. show that a distinct increase in agglutinins for the diplococci isolated from measles blood occurs in measles on the 3rd to the 8th day following the appearance of the eruption. The agglutination appears to be sp. for the measles diplococcus, no agglutinins being observed for pneumococcus types I and II, and *Streptococcus hemolyticus*. The agglutinins are present in the blood when the opsonic power is at its height and when complement-fixing bodies are demonstrable. JULIAN H. LEWIS.

**Studies in cholelithiasis. III. The immediate effect of operations upon the cholesterinemia.** ABRAHAM O. WILENSKY AND MARCUS A. ROTHCHILD. *Am. J. Med. Sci.* 156, 564-74(1918); cf. *C. A.* 13, 340.—The blood cholesterol content is modified after cholecystectomy only where complications arise. Where obstructions are removed, the cholesterol content becomes normal. W. MORSE.

**Reinfection with *Streptococcus hemolyticus* in lobar pneumonia, measles and scarlet fever and its prevention.** LOGAN CLENDENING. *Am. J. Med. Sci.* 156, 575-86(1918).—Reviews of the work of Cole and McCallum, of Irons and Marine, of Hamburger and Mayers of Cummings, and of Spruit and Lynch, who reported from various camps in the United States. Carriers are responsible, in the wards; hence isolation is resorted to. W. MORSE.

**Fat redistribution in the hypophyseal type of dystrophy adiposogenitalis.** HARVEY G. BECK. *Am. J. Med. Sci.* 156, 711-20(1918).—Return to practically normal dimensions of the buttocks and thighs occurred in several cases of females following administration of hormatone and of thyroid. The diet remained unchanged. The fate of the redistributed fat was not detd. W. MORSE.

**Complement fixation in Hodgkins disease and allied infections.** H. T. KRISTJANS. *Am. J. Med. Sci.* 156, 720-5(1918).—Using *B. hodgkini*, a positive, sp. reaction may be given. Exptl. animals give a sp. reaction. The limited number of normal cases examd. gave no reaction. W. MORSE.

**Certain aspects of the clinical value of the estimation of kidney function.** EDWARD H. MASON. *Am. J. Med. Sci.* 156, 830-8(1918).—A test meal should be examd. correlative with the rate of urea excretion, chlorides and phenolsulfonephthalein. Digitalis lowers the threshold for chlorides. W. MORSE.

**Alkaline reserve content of blood serum in wounded soldiers.** EDGARD ZUNZ. *Compt. rend. soc. biol.* 81, 144-6(1918).—The Marriott method for detg. the alk. reserve content of blood serum was employed. In general, a decrease in alk. reserve of the serum of wounded soldiers was observed in cases of relatively

pronounced infection, diminished respiration due to insufficient oxygenation and in serious intestinal intoxication. *Streptococcus* and *B. perfringens* were almost always present in infections which were accompanied by pronounced acidosis. Alkaline reserve values of 7.9-8.2 and 7.7-8.2 were noted in streptococcic septicemia and serious gaseous gangrene, resp. The alk. reserve content was normal in cases of contusion and closed fracture without fever or infection; the same was true in cases of open fracture and wounds (even multiple) of the fleshy parts of the body, provided there was no fever or infection. The periods of min. content of alk. reserve coincided with the max. of infection and also with the periods of max. leucocyte content of the blood. The alk. reserve content may, however, return to normal while the leucocyte content of the blood is still high and before the infection has entirely disappeared. Only moderate acidosis was noted in staphylococcic septicemia, the values of alk. reserve content being 8.1-8.3. Broncho-pneumonia was accompanied by notable decrease in alk. reserve. In conditions of circulatory collapse detd. by hemorrhage or infection during the 1st few hrs. following infliction of the wound the alk. reserve content decreased considerably (to 7.6-7.95). In the case of intoxication by asphyxiating gases or gases with irritant action on the tracheo-bronchial mucosa the alk. reserve content either remained normal or decreased only slightly; in cases of the foregoing where broncho-pneumonia or pulmonary edema ensued the alk. reserve content decreased to 7.5-7.9. The prognosis is generally unfavorable in all cases in which the alk. reserve content of the serum is less than 7.8. H. S. PAINE.

**Antitryptic index of the blood serum of wounded soldiers.** EDGARD ZUNZ AND PAUL GOVAERTS. *Compt. rend. soc. biol.* 81, 146-8(1918).—Contusions and minimal closed fractures have a negligible influence on the antitryptic index of the serum. Closed fractures of the limbs may cause a transitory increase; the latter may be detd. by other factors than infection and has sometimes a purely traumatic origin. In wounds where the infection remains superficial and does not cause fever the modifications of the antitryptic index follow the same course (with the same amplitude) as in aseptic lesions; they appear to depend on the initial traumatism. In febrile conditions the antitryptic index attains a distinctly higher value than in cases where no fever ensues; the curves of temp. and antitryptic index are parallel in their general course. The value of the antitryptic index in the wounded is dependent on 2 principal factors, i. e., the initial traumatism and the degree of fever. The intervention of these factors probably explains the frequent flattening of the antitryptic curve after 10-15 days in patients with infected wounds, this change being then followed by another rise in the curve; this flattening of the curve doubtless corresponds to the period when the influence of the initial traumatism ceases to be effective. Increase in antitryptic index may be entirely absent in conditions of circulatory collapse detd. by hemorrhage or infection during the 1st few hrs. following infliction of the wound. The same is true in septicemia (*streptococcus*, *staphylococcus*, *B. perfringens*). In some cases the antitryptic index only increases in gaseous gangrene at the moment when the virulence of the infection appears to diminish. Intoxications due to asphyxiating or lachrymal gases cause little or no change in the antitryptic index. In the evolution of an infected wound the curve of leucocytosis and that of the antitryptic index are only parallel during the 1st few days of the infection. No parallelism between the variations in antitryptic index and the variations in the alk. reserve content of the serum was observed. A table is given showing the max. values of the antitryptic index in various pathol. conditions. The highest values were found in cases of wounds, open fractures, crushed limbs, etc., accompanied by prolonged infection and fever. H. S. PAINE.

**Oxidotherapy in the treatment of tetanus.** M. BGLIN. *Compt. rend. soc. biol.* 81, 172-4(1918); cf. *C. A.* 12, 722.—The term "oxidotherapy" is applied by B. to the

treatment of various diseases by injection (subcutaneous, intramuscular, intravenous) of oxidizing agents (such as  $\text{KClO}_3$ ,  $\text{KMnO}_4$ , etc.). Gradual disappearance (complete after 30-45 min.) of contractions was observed after injection of 2 cg. per kg. of  $\text{KClO}_3$  (1:40 soln.) in a rabbit on the day following injection of 1.5 cc. of a 36-hr. culture of tetanus bacilli (in peptone broth) in the region of the shoulder. The action of oxidizing agents was *nil* in the case of generalized contractions. General amelioration of symptoms was noted in horses with tetanus after successive injections of 1:250 or 3:1000  $\text{KMnO}_4$  solns.

H. S. PAINE.

**Respective roles of serine and globulin in the sigma reaction.** LOUIS BORY. *Compt. rend. soc. biol.* 81, 247-8 (1918).—Since a positive sigma reaction is still obtained when a horse globulin soln. in appropriate amt. is substituted for sp. serum in the required system excess of globulin may be regarded *a priori* as a characteristic of the sp. sera. B. has investigated the behavior of serine under the same conditions. Serine was found to cause fixation of complement (guinea pig complement and Desmoulières antigen), but this likewise occurred in the absence of antigen. Similar results were obtained when serine in increasing amts. was added to a sigma-negative serum in a complement fixation expt. Globulin, on the contrary, only transformed the negative serum into a positive serum in the presence of antigen; this change was proportional to the increase in concn. of globulin. The serum appeared, however, to contain a substance which opposed the fixative power of globulin in the presence of antigen; this was shown by comparison of the usual system with the same system after omission of the negative serum. This substance is apparently serine; globulin and serine appear to play opposite roles in the Wassermann reaction.

H. S. PAINE.

**Constancy of alexin in the blood stream; deplementized sera.** RENÉ BENARD. *Compt. rend. soc. biol.* 81, 281-2 (1918).—Complement was invariably found to be present in approx. 300 sera which were investigated by collecting the blood in an oxalate soln., centrifuging and bringing the supernatant plasma in contact with an inactivated hemolytic system. On the other hand the sera obtained from these same samples of blood after coagulation were found to be practically devoid of complement in 18% of the cases, disappearance of complement having occurred within 13-20 hrs. after withdrawal of the blood; hemolysis was absolutely *nil* in 11% of these cases and very slight in 7%. The difficulty due to possible use of sera devoid of complement in simplified Wassermann procedures may be avoided by using oxalated plasma. Sera may become more or less deplementized, but sera naturally devoid of complement do not occur.

H. S. PAINE.

**Investigation in horses with typhoid affections of agglutinins and the sensitizing substance corresponding to the equine paratyphoid bacillus.** RAOUL COMBES. *Compt. rend. soc. biol.* 81, 288-91 (1918); cf. *C. A.* 12, 1989.—In addition to the equine streptococcus there were found in the lesions presented by horses and mules with typhoid affections a bacillus (I) of the paratyphoid group and a bacillus (II) of the *Pasteurella* type (but rapidly producing indole in peptone media); C. designates I as "equine paratyphoid bacillus." The sera of healthy horses, of horses with non-typhoid affections and of horses with typhoid affections (bacillus II present and I absent) failed to agglutinate bacillus I at dilns. greater than 1:100. The sera of horses with typhoid affections (bacillus I present) agglutinated this bacillus at high dilns. (max. 1:4000); the sera of these horses contained the sensitizing substance (complement fixation) corresponding to this bacillus. Horses with typhoid affections may by the above serum reactions be sepd. into 2 groups, *i. e.*, (1) those which are and (2) those which are not carriers of the equine paratyphoid bacillus.

H. S. PAINE.

**Determination of sugar in the cerebrospinal fluid; semeiological value of hyperglucorachia.** MATHIEU-PIERRE WEIL. *Compt. rend. soc. biol.* 81, 364-7 (1918).—

Change in content of glucose is the most sensitive indication of modification of the cerebrospinal fluid; this change precedes all others, especially increase in albumin content. Detn. of sugar should be effected immediately after withdrawal of the cerebrospinal fluid; otherwise the sugar content may be diminished by bacterial action (pathol. or accidental infection) or it may be increased in the case of cerebrospinal fluid rich in cellular elements (possibly through liberation from the latter of carbohydrate groups of the nucleoprotein content). Samples which cannot be examd. at once should not only be kept under aseptic conditions but should also be centrifuged to remove cellular elements. The methods of Grimbert and Bertrand are recommended for detn. of sugar. The difficulty encountered with the latter method owing to the relatively small vol. of cerebrospinal fluid available and the amt. (10-100 mg.) of glucose required to be present in order to secure a satisfactory detn. may be obviated by adding to the clarified fluid an accurately known amt. (e. g., 10 mg.) of glucose before making the detn. The sensitiveness of the Bertrand method is increased by using a 1.25:1000 instead of the 5:1000 KMnO<sub>4</sub> soln. recommended by B. The normal sugar content of the cerebrospinal fluid is 0.46-0.52 g. per l.; values lower than 0.40 g. and higher than 0.60 g. per l. are pathol. Hyperglucorachia was observed in a no. of patients with paralytic syndromes due to lesion of the central nervous system and also in cases of sciatic neuritis and alc. polyneuritis. Change in the glucose content of the cerebrospinal fluid may be indicative of the participation of the spinal cord in many toxic-infectious conditions of the organism. Hyperglucorachia is coincident with congestion of the meninges and may be regarded as an index of the same, osmosis being facilitated by congestion. The hypothesis of hyperemia as a factor in production of hyperglucorachia is consistent with the frequently transitory character of the increase in sugar content of the cerebrospinal fluid.

H. S. PAINE.

**Hyperglucorachia of shell shock.** MATHIEU-PIERRE WEIL. *Compt. rend. soc. biol.* 81, 367-9(1918); cf. preceding abstract.—Detn. of the sugar content of the cerebrospinal fluid is of primary importance in the study of shell shock for the purpose of differentiating between purely nervous manifestations and those which have an organic basis. In the latter case values of 0.61-0.77 g. per l. were encountered, while in the former case the values were normal (0.44-0.49 g. per l.). In most cases of shell shock the cerebrospinal fluid showed no abnormality other than increase in sugar content. The congestion in cases of shell shock with organic basis may result only in hyperglucorachia or it may be sufficient to produce meningeal hemorrhage.

H. S. PAINE.

**Conditions of circulatory collapse.** P. GOVAERTS AND E. ZUNZ. *Compt. rend. soc. biol.* 81, 881-4(1918).—In an investigation of the factors causing the condition of circulatory collapse during shock G. and Z. studied the changes in alk. reserve by the method of Marriott. When arterial pressure was less than 50 mm. Hg the alk. reserve of the serum diminished, regardless of the cause of circulatory collapse; this decrease appeared more quickly and was more pronounced when the decrease in pressure was due to acute infection. Removal of a leg (exptl. study of traumatic circulatory collapse in dogs) caused no distinct change in the alkaline reserve. The latter diminished whenever a condition of low pressure was produced by a combination of traumatism and moderate hemorrhage. In no case did it appear that decrease in alkaline reserve could be regarded as a cause of circulatory collapse.

H. S. PAINE.

**Value of modern blood chemistry to the clinician.** A. O. GETTLER AND A. V. ST. GEORGE. New York. *J. Am. Med. Assoc.* 71, 2033-6(1918).—Following are a part of the conclusions based upon a study "of some 15000 detns., the largest ever reported." Kidney function may be ascertained by the increased values of non-protein N, urea N, creatinine, and uric acid; that is, whether a derangement of the elimination of the

waste N products exists. The severity of this derangement can be ascertained and the prognosis detd. Hyperglucemia can be detected with certainty by the increased value of the blood sugar content, even in the earliest stages of diabetes, when the urine is still free from sugar. Acidosis and its degree can be detd. by the decreased value of alk. reserve of the blood as measured by the Van Slyke CO<sub>2</sub> app. By reducing in the blood of the patient the precursor of the particular substance formed in excessive amts. in the blood, good results are obtained. L. W. RIGGS.

## I. ZOÖLOGY.

R. A. GORTNER.

Suggestions regarding the causes of bioelectric phenomena. L. H. HYMAN. *Science* 48, 519-24(1918).—H. reviews the work of Child, Lillie, Waller, Tashiro and many others. Following are some of the suggestions and conclusions: The electrical difference of potential in the organism is due to the difference in rate of oxidation at different levels. The stimulation of injury produces in the organism an increase in the metabolic rate; hence it is argued that the current of injury arises through the fact that the site of injury and adjacent regions are regions of increased metabolic rate and thus are electronegative to intact regions where the rate is lower. A region whose metabolic rate has been temporarily increased by stimulation is electronegative to such non-stimulated regions. The various kinds of bioelectric currents are thus conceived

as referable to differences in metabolic rate; and they are apparently merely the consequence of such differences and of no significance in themselves. The metabolic gradient also furnishes a logical explanation of the phenomena of galvanotaxis. L. W. R.

**Nature of pigmentation changes following hypophysectomy in the frog larva.** WAYNE J. ATWELL. Univ. Buffalo. *Science* 49, 48-50(1919); cf. B. M. Allen, *C. A.* 11, 1998, 3059; 12, 1083 and P. E. Smith, *C. A.* 12, 2385.—The conclusions of Allen and Smith were based upon a study of sections, while Atwell's studies were made upon pieces of skin of *Rana sylvatica* mounted entire. When hypophysectomized tadpoles which had reached the silvery appearance were placed in a dil. ext. of pars intermedia of beef pituitary or in an emulsion made by shaking a few mg. of dried pars intermedia in 100 cc. of water, the silvery appearance changed to dark so that they resembled normal tadpoles. The change began to be apparent in 15-30 min. and attained a max. in 1 to 3 hrs. depending upon the concn. of the emulsion employed. When returned to fresh water the silvery appearance was regained in 1 to 3 hrs. This proves that the silvery appearance is not due to loss of pigment but to a sustained contraction of the pigment-bearing cells, which may be caused to expand again by suitable stimuli. This view is supported by watching under the microscope larvae held in a Clarke's observation chamber. The final conclusion is that the change in color is primarily due to a contraction of the sub-epidermal melanophores. Only secondarily is it due to a loss in pigment granules from certain of the epidermal melanophores and to a possible migration or loss of other epidermal melanophores. L. W. RIGGS.

**Pigmentation of a clypeastroid, *Mellita sesquiporforatis* Leske.** W. J. CROZIER. *Am. Nat.* 52, 552-6(1918).—In the abstract of this article in *C. A.* 13, 343, there is an error in the page reference to the original. L. W. RIGGS.

BRACHET, A.: *L'oeuf et les facteurs de l'ontogénèse*. Paris: Doin. 349 pp. 6 francs. For review see *Rev. sci.* 56, 62(1918).

---

## 12. FOODS.

---

W. D. BIGELOW AND F. F. FITZGERALD.

**Jelly making with sugar savers.** LUCILE W. ADAMS AND ETHEL LOFLIN. *J. Home Econ.* 10, 503-10(1918).—Where all of the sucrose is replaced by other sweeteners as glucose, honey, corn sugar or sorghum, the jelly is darker in color and the texture less tender. However, sweeteners modify the flavor of the jelly little. The sweetening power of the various sirups varies, also their jelling point. The substitution of 50% sweeteners in place of sucrose gave the best results in most cases.

HELEN N. ELLIOTT.

**The chemistry of sweetening agents.** FRANCOIS BARRAL AND ALBERT RANC. *Rev. sci.* 56, 712-23(1918).—Taste is affected by variation of the constitution of the mol. Introduction into the mol. of a sweet substance of any radical, especially an aromatic one, destroys the sweet taste, giving a bitter one. The heavier the fixed mol., the more marked is the modification. Nitration causes disappearance of sweetness as does the introduction of halogens. Introduction of halogens into the hydrocarbons and the adding of OH to an NH<sub>2</sub> group produce a sweet taste. The methoxy group introduced into an aromatic mol. changes bitterness to sweetness. Polyhydroxyl compds. are sweet and poly-nitrated compds. are bitter, but exceptions are noted in complex mols. No general law is known to predict the taste of a compd. when the mol. structure is known. Taste is influenced by so many things that it is impossible to study it satisfactorily. LOTTIE M. MANROSS.

**Examination of saccharin tablets.** H. DROOP RICHMOND, SEPTIMUS ROYCE AND CHAS. ALFRED HILL. *Analyst* 43, 402-4(1918).—Of saccharin tablets (219 samples) the manuf. of which is controlled 48% conformed with the standard and the remainder were within 10%. Uncontrolled samples (168) showed strength far below the controlled article. The principle of the method of R. and H. (*C. A.* 12, 2215) for estn. of saccharin was used. The boiling with alkali is dispensed with as the soap in some tablets causes frothing.

H. A. LEPPER.

**Sugar-saving substitutes in ice cream.** J. H. FRANDSEN, J. W. ROVNER AND JNO. LUTHELY. *J. Dairy Sci.* 2, 32-40(1919).—Four formulas are given which save 30-50% of cane sugar by use of corn sirup, corn sugar, or invert sirup. All the cane sugar could not be satisfactorily replaced. Also in *Nebr. Agr. Sta., Bull.* 168, 7 pp. H. A. L.

**The manufacture of Neufchatel and cream cheese in the factory.** K. J. MATHE-SON AND F. R. CAMMACK. U. S. Dept. Agr., *Bull.* 669, 28 pp.(1918).—Milk containing 4% butter fat is required for making Neufchatel cheese, while a butter fat content of 6 to 8% is required for cream cheese. The details of the manuf. of each is given. The cheese should be kept at a temp. of 40° to 50° until consumed.

J. J. SKINNER.

**Buttermilk cheese.** A. W. RUDNICK. *J. Dairy Sci.* 2, 41-5(1919).—Cheese can be made from butter-milk commercially by use of a centrifugal machine to sep. the curd and whey. A good grade milk makes a cheese similar to cottage cheese and fit for human food. Acidity, temp. and time of holding were found to be the main factors influencing the completeness of extn. of the whey.

H. A. LEPPER.

**The use of an acid in the Roese Gottlieb method for fat in dried buttermilk.** J. H. ROOP. *Chem. Analyst* 26, 21(1918).—Transfer 1 g. sample to the Rhorig tube, add 1 cc. 1:1 H<sub>2</sub>SO<sub>4</sub> and 9 cc. H<sub>2</sub>O. Digest on the steam bath for 30 min. The casein becomes flocculent. Add 10 cc. EtOH, 25 cc. Et<sub>2</sub>O, 25 cc. petroleum ether and shake. The ether layers are readily sepd., and results are said to be extremely accurate. The use of acid instead of the usual NH<sub>4</sub>OH is advantageous, because the fat is thereby more easily dissolved from the casein particles, and the formation of persistent emulsions is avoided.

H. M. LANCASTER.

**Note on the graduation of Gerber butyrometers.** H. DROOP RICHMOND. *Analyst* 43, 405(1918).—A discussion of slight errors in the formula of Day and Grimes (*C. A.* 12, 1353).

H. A. LEPPER.

**An oxidation method for the determination of lignin-free crude fiber in cocoa.** TH. VON FELLEBERG. *Mitt. Lebensm. Hyg.* 9, 277-83(1918).—Oxidize lignin by heating with dil. HNO<sub>3</sub> to substances sol. in alkali. Free 1 g. cocoa or 2 g. chocolate from fat by ether and then boil with 15 cc. N HNO<sub>3</sub> for 10 min. Filter on gooch, wash with hot water, hot 1% NaOH, hot HNO<sub>3</sub>, dil. NH<sub>4</sub>OH, hot water, alc. and ether. Dry and weigh to get lignin-free crude fiber, plus sand. Ignite and weigh sand. The value found for 13 samples of beans was from 3.68 to 5.27% (av. 4.4%), and for the shells was from 9.59 to 22.04% (av. 18.3%).

H. E. WOODWARD.

**Course of instruction in the inspection and reception of meats for the army.** *Bull. sci. pharmacol.* 25, Pt. I, 101-5(1918).—See also Pommier, *Inspection of meats*, Lyons, 1911.

M. HEIDELBERGER.

**Examination of fish.** P. K. W. BØKMAN. *Tidsskrift Kemi.* 15, 64-7(1918).—The method of Sørensen for the detn. of amino N by formol titration is applied to the detn. of the changes in the fish flesh and thereby in the evaluation of the quality of the fish as food. It is recommended also for meats. Twelve-day old fish-store samples gave a formol titratable N of 2.43%. These samples did not give positive tests

for  $\text{NH}_3$ . The figures for samples of fish in which the  $\text{NH}_3$  test was positive but not for  $\text{H}_2\text{S}$  ranged from 2.56 to 2.96.

A. R. ROSE.

Analysis of fish extracts. F. DE LEMOS. *Tidskrift Kemi*. 15, 61-4(1918).—Analytical data.

A. R. ROSE.

Bacteriological examination of canned foods. A. W. BITTING AND K. C. BITTING. Nat. Canners' Assoc., *Bull.* 14, 47 pp.(1918).—The object of bacteriol. examn. is three-fold: (1) To see if those foods which appear normal are sterile; (2) to find out whether foods which appear defective are sterile and whether spoilage is due to under-processing or leaks; (3) to det. the character of the original material from the finished product. (1) is done in packing; (2) after evidence of spoilage; (3) mostly upon tomato products. Explanation of terms used in food preserving, an outline of the method of examg. canned foods and of detecting defective cans, as well as an explanation of springers, improperly filled cans, leaks, swells and flat sour are given. Organisms found in cases of spoilage and the cause for variations of the number present are discussed.

LOTTIE M. MANROSS.

Reports of storage holdings of certain food products. J. O. BELL AND T. C. FRANKLIN. U. S. Dept. Agr., *Bull.* 709, pp. 44(1918).—Monthly cold storage holdings of a number of food products are given.

J. J. SKINNER.

Wheat. ANON. Council of Science and Industry, Australia, *Bull.* 5; *Bull. Imp. Inst.* 16, 249-50(1918).—Wheat after being freed from foreign matter by screening is mixed with 1% its wt. of hot, freshly burnt  $\text{CaO}$  and quickly transferred to a brick or stone silo until required for use. It should then be freed from  $\text{CaO}$  by suction and sifting machinery. It was found that such treatment considerably reduced the bacteria on the outer layers of grains. The degree of deterioration of wheat is indicated by the  $\text{NH}_3$  content of the  $\text{H}_2\text{O}$  ext. Damaged samples yield 8-12 times as much  $\text{NH}_3$  as clean wheats on extn. with  $\text{H}_2\text{O}$ . Treatment with  $\text{CaO}$  is also good for partially rotted wheat and for mousey tainted wheats, but probably not for weevils.

R. L. SIBLEY.

The composition of natural and polished Italian rice. I. GIOVANNI ISSOGLIO. *Atti accad. sci. Torino* 53, 731-44(1918).—Seven varieties of rice were examined, two being native and the remainder polished. Polishing reduced the total ash (from 1.4% native to about 0.5% polished), the ash content which is sol. in  $\text{HCl}$  being the principal portion affected. Lecithin, detd. as  $\text{P}_2\text{O}_5$ , was reduced to a trace in polishing, this component being present in unpolished rice at about 0.1%. The water content remained practically const. after polishing. Cl likewise remained const.

W. MORSE.

The digestibility of bran. GEORG WIEGNER. *Mitt. Lebensm. Hyg.* 9, 289-99 (1918).—As the result of expts. of several investigators, W. concludes that man digests bran as well as ruminants and swine. The evidence seems to be in favor of a whole-grain bread of a moderate coarseness.

H. E. WOODWARD.

The drying of vegetable substances carried out at different temperatures. G. ANDRÉ. *Bull. soc. chim.* 23, 430-7(1918).—A series of expts. on leaves (lilac, syringa, and maple), was carried out with the following app. A porcelain dish containing the leaves is put into a glass tube which is thrust into a  $\text{Cu}$  tube embedded in a regulated oil bath. A tube in which dry air circulates and a long thermometer with its reservoir just above the dish, pass through the stopper of the glass tube. The difference in wt. of the dish before and after heating gives the quantity of water lost by the leaves. The loss of water which accompanies the drying of the leaves or shoots, even up to a temp. of  $120^\circ$ , takes place slowly in a current of dry air. The speed is the same in dry  $\text{H}_2$ . The loss of  $\text{CO}_2$  which takes place during drying is very small.

LOTTIE M. MANROSS.

**Nutritive value of leaves.** H. EDIN. *Kungl. Landbruks-Akad. Handlingar Tidskrift*. 57, 397-417(1918).—This is one of a series of articles (cf. C. A. 12, 838, 1404) which have appeared in this journal on the nutritive value of leaves of possible fodder value for the stock of the North European countries. They are probably of little practical value for the chemists and nutritionists of America. Scientists interested along these lines will find considerable data in Vol. 57 of this journal as to the compn. and digestion of leaves of several trees, grasses, mosses, sea greens, and straws. The straw is treated to render it more digestible and palatable. Some of the articles treat of materials from the point of view of availability as human food. There are also some data on barks.

A. R. ROSE.

The results of microbiological and chemical investigations on the question of sweet green feed. R. BUNRI AND P. LIECHTI. *Mitt. Lebensm. Hyg.* 9, 287-8(1918).—While the feeding of sweet green stuff does not change the food value of cow milk, the milk cannot be used for making certain kinds of cheese. The loss and change in compn. is no greater in sweet green feed than in dry feed.

H. E. WOODWARD.

The presence of acetylmethylcarbinol in saccharin sorghum silage. W. G. FRIEDMANN AND C. T. DOWELL. *J. Ind. Eng. Chem.* 11, 129-30(1919).—Saccharin sorghum silage was found to contain AcMeCHOH, a volatile reducing substance previously found in cider vinegar. Cf. C. A. 11, 1001.

H. A. LEPPER.

Experiments of the experimental dairy station at Hoorn with the "Notfutter" of Prof. v. Calcar. J. J. OTT DE VRIES. *Vereeniging tot exploitatie eener proefsuivel-boerderij te Hoorn; Jahresbericht* 1916, 86; *Biedermanns Zentr.* 47, 176-80(1918).—This feed was prepared from mussels (with shells), fish unfit for trade, blood, and a variety of vegetable wastes. Feeding and digestion expts. were carried out with swine. The conclusions drawn are: (1) Barley and whey contain too little CaO for normal bone production in rapidly growing fattening swine so that addition of CaO in any form is always beneficial. (2) Mixed feed prepared according to Prof. v. Calcar's direction because of its content of fish meal contains, even without mussel shells, sufficient CaO for direct nutrition. (3) The increase in the digestibility of crude fiber, due to CaO, cannot be of importance in consequence of the low content of this food constituent and because of the easy digestibility of the crude fiber of the pods of legumes. (4) The digestible org. constituents amount to 54% of the feed, the content of digestible protein to 12.4%. (5) Without the mussels the "Notfutter" shows considerable similarity in food value to peas.

ALBERT R. MERZ.

The extent to which potatoes are utilized when fed in various forms (raw and cooked potatoes, raw and cooked silage-potatoes and dried potatoes—flakes and chips) to swine and ruminants. W. DIETRICH, A. DEUTSCHLAND, N. MUHR, A. BAUMANN AND W. VOLTZ. *Landw. Jahrb.* 50, 455-518(1917); *Biedermanns Zentr.* 47, 169-76(1918).—The digestion coeffs. of the various nutrients of these foods are given for swine and sheep.

ALBERT R. MERZ.

SJOLLEMA, B.: *Nieuwe gezichtspunten in de voedingsleer*. 2nd Ed. Revized and enlarged. Tiel: A. van Loon. 87 pp. For review see *Chem. Weekblad* 15, 1644(1918).

**Food product from milk.** P. W. TURNER. U. S. 1,289,021, Dec. 24. Fresh milk is treated with an enzyme such as rennet or pepsin and allowed to stand until it has curdled and the ppt. has assumed a flocculent, slightly adherent consistency. The material is then quickly cooled to inhibit further curdling and the mass is gently agitated to effect sepn. of the whey which is poured off after allowing the ppt. to settle,

the whey is concd., mixed with the ppt. previously sepd. from it and the mixt. is kept at a low temp. to preserve it in suitable condition for use as a food.

**Artificial milk.** K. ERSLEV. Brit. 121,133, Nov. 28, 1918. In making artificial milk from vegetable substances such as soy beans, earth nuts, pine kernels, sesame seeds, leguminosae in general, coconuts, palm kernels, or almonds, especially such as contain sugar and lecithin, the material is first treated with a solvent to ext. fat and then extd. with alc. The alc. ext. is evapd. to dryness and treated to remove any bitter taste. The residue from the alc. extn. is treated with a weak alk. soln. to dissolve proteins, and the ext. thus obtained is mixed with the treated material from the alc. ext. The substance thus obtained may be used in the manuf. of margarine. It may also be emulsified with fat, especially the fat originally extd. to produce artificial milk. The residue, after extn. with alkali, may be used as a cattle food.

**Butter substitutes.** H. GORTON. Brit. 120,836, Feb. 28, 1918. Mfg. margarine by adding egg albumin to the usual oil and fats and  $H_2O$  and churning the mixt. in the usual manner, without the addition of an emulsifier other than the albumin, and at a temp. above the m. p. of the fats employed and below the coagulation point of the albumin.

#### 14. WATER, SEWAGE AND SANITATION.

EDWARD BARTOW AND W. F. MONFORT.

**The color and decolorization of water.** A. MASSINK. *Water* 2, 42; *Chem. Weekblad* 15, 1388(1918).—To find why waters of the same color intensity are not always decolorized at the same rate, the influence of various salts was studied. It was found that the decolorizing action of  $Fe(OH)_3$  suspension decreases with increasing concn. of the  $HCO_3^-$  ion. This fact can be made use of for more accurate titration of bicarbonate in colored waters.

JULIAN F. SMITH.

**The importance of electrical conductivity in the analysis of potable waters.** I. M. KOLTHOFF. Utrecht. *Chem. Weekblad* 15, 1160–83(1918).—The purpose of this investigation was to study the mutual influence of various salts on their dissociation in aq. soln. The work of previous investigators in the field of analysis by cond. detns., particularly Kohlrausch and Holborn, is reviewed. The ions in a normal water can be quickly detd., titrating  $Cl^-$  with  $AgNO_3$ ,  $HCO_3^-$  with acid using methyl orange as indicator, and  $SO_4^{--}$  iodometrically by the  $BaCrO_4$  method. Hardness is also easy to det. by Blacher's method. If no abnormal constituents are present, the alkali content can be calcd. by subtracting the hardness from the sum of the anions. But these methods give no control over the total analysis. If the degree of dissociation ( $\lambda$ ) is known for each salt present, the total cond. can be calcd. The observed cond. should be used as a control. To make such a calcn. accurate, the influence of different salts on each other should be known. Studies of this influence were made in various mixts. With  $NaCl$  and  $CaCl_2$  or  $MgCl_2$  in 0.1 N soln. at 18°, the calcd. sum agreed very closely with the observed total cond. With  $NaCl$  and  $Na_2SO_4$  in varying proportions (concn. 0.1 N), the calcd. values were from 0.6 to 2.3% too high. With  $CaCl_2$  and  $CaSO_4$  in 0.1 N soln., the calcd. values were 2.5 to 3% too high, but agreed more closely in 0.01 N soln. For mixts. of salts having no common ion, there was observed the general rule that  $\lambda$  for each salt is equal to the value corresponding to the total concn. of electrolytes. Gypsum is an exception; its value of  $\lambda$  is that corresponding to the total concn. of  $Ca^{++}$  and  $Mg^{++}$ . This rule is important for calcg. the cond. of potable waters of known compn. Tables, and directions for their use in making the necessary calcns., are appended to the article.

JULIAN F. SMITH.

**Chlorine treatment of London, England water supply.** A. C. HOUSTON. *Ann. Report Metropolitan Water Board, Year ending Mch. 31, 1918*; *Mun. County Eng.* 56, 29-30(1919); *Eng. Contrg.* 50, 414-5.—The charge has varied; usually 0.5 p. p. m. available Cl causes no complaint of tastes. Extreme cold and short contact are troublesome factors. Dechlorination with  $\text{SO}_2$  has been helpful in reducing taste.

LANGDON PEARSE.

**Toronto's drifting sand filter.** G. G. NASMITH AND N. J. HOWARD. *Munic. J.* 45, 390-2(1918); *Eng. News-Rec.* 81, 817-8(1918); *Can. Engr.* 35, 359-64(1918).—Results are detailed. During the test 1.02 grains of  $\text{Al}_2(\text{SO}_4)_3$  were used, with turbidity of raw water running from 1 to 115 p. p. m. The total bacterial reduction averaged 93.9%. With raw water running between 50 and 500, 97% were removed. In water under 45° F. floc forms more slowly.

LANGDON PEARSE.

**Performance of the Ransome drifting sand filters at Toronto, Ontario.** JOSEPH RACK. Committee on Water Supplies, *Am. Pub. Health Assoc.* 1918; *Munic. County Eng.* 56, 15(1919).—Operating results are given for Toronto filters. Chloramine treatment at Ottawa has been successful reducing dose from 0.75 p. p. m. available Cl with bleach to 0.25 p. p. m. with 0.06 p. p. m. of  $\text{NH}_3$  when water is near freezing, and to 0.5 p. p. m. when water is near 75° F. Cost is now greater, owing to high cost of  $\text{NH}_3$ .

LANGDON PEARSE.

**Advantages and disadvantages of the storage of water.** M. C. WHIPPLE. School of Public Health, Boston, 1918. *Eng. Contrg.* 50, 468-9(1918).—See C. A. 12, 2639.

LANGDON PEARSE.

**Chicago introduces new chlorinator.** JOHN ERICSON. *Munic. County Eng.* 56, 6-8(1919); *Eng. News-Rec.* 81, 1126-7(1918).—See C. A. 13, 49.

L. P.

**Coagulants versus sand filters as aids to water purification in the field.** H. S. BRIGGS AND E. E. MARLE. *Royal Engineers Journal* 1918; *Eng. Contr.* 50, 399-400(1918).—The authors describe temporary field practice in the British Army in Flanders, on a plant of max. capacity 300,000 gal. per day. They recommend liberal chem. treatment ( $7\frac{1}{2}$  to 20 grains per gal.) and 8 to 12 hrs. sedimentation followed by Cl disinfection.

LANGDON PEARSE.

**Taking a chance with an unsafe water supply proves costly.** *Ohio Pub. Health J.* Nov., 1918; *Munic. County Eng.* 56, 15-16(1919).—A typhoid epidemic resulted from imperfect disinfection with low-strength bleaching powder found to contain 20% of guaranteed strength.

LANGDON PEARSE.

**Findings of international joint commission on pollution of boundary waters.** F. A. DALLYN. *Am. Soc. Mun. Impol.* 1918; *Eng. Contrg.* 50, 459(1918); *Can. Engr.* 35, 323-5.—Extracts from a report stating a standard for Detroit and Niagara rivers, and indicating treatment where the flow of the diluting stream is less than 4 cu. ft. per sec. per capita, or water contains more than 500 *B. coli* per 100 cc.

LANGDON PEARSE.

**Sewage treatment in Eastern Pa.** ANON. *Munic. J.* 45, 386-8(1918).—Sewage treated with lime (1 ton 56% CaO per mil. gal.) passes between Fe plates serving as electrodes for d. c. to final sedimentation.

LANGDON PEARSE.

**Operating sewage plants.** Texas State Bd. Health, *Bull.* 1918; *Munic. J.* 45, 327-8(1918); *Eng. Contrg.* 50, 548-9(1918).—Instructions are given for operating sewage plants.

LANGDON PEARSE.

**Four methods of sewage treatment studied at New Haven testing station.** C. E. A. WINSLOW AND F. W. MOHLMAN. *Eng. News-Record* 82, 32-6(1919); *Munic. J.* 45, 280-2, 297-9, 321-2(1918); *Munic. County Eng.* 55, 173-5.—Eleven-month test at a cost of \$18,000 led to the conclusion that for 1 of 4 sewage-treatment works Miles' acid

process is best available, under local conditions. The sewage of 160,000 people now grossly pollutes the harbor, rendering shell-fish unfit to use and bathing dangerous. Fine screening, Imhoff tanks and activated sludge treatment (all with subsequent Cl disinfection) and Miles' acid pptn. with  $\text{SO}_2$  were tried. The sewage at times was low in bacteria because of Cu salts from munition works. Screens (30-mesh) removed from 12 to 15% suspended matter; slotted plate screens ( $1\frac{1}{4} \times \frac{1}{8}$  in. openings) removed 3 to 8% suspended matter. Imhoff tank removed 43% suspended matter but sludge was extremely abnormal, dewatering badly. The activated sludge process was not satisfactory because of antiseptic industrial waste. The amt. of Cl required for disinfection with activated sludge was 3 p. p. m., with Imhoff tank 6 p. p. m., with screen 5 p. p. m., and with crude sewage 8 p. p. m. Miles' acid treatment removed 61% suspended matter, gave clear effluent with marked bacterial reduction, and resulted in freedom from odor. The recovery of grease is apparently possible, though not commercially demonstrated. Higher alkalinity in other sewages makes cost of process higher and less favorable for other 3 plants.

LANGDON PEARSE.

Sewage sedimentation advised for Cleveland, Ohio. H. P. EDDY. *Report to Chf. Engr. Dept., Pub. Service* 1918; *Eng. News-Rec.* 81, 806(1918).—Imhoff tanks with Cl disinfection are recommended for plants on the lake shore in preference to screens and disinfection, to insure greater efficiency in protecting bathing beaches. During storms, bathing must be stopped because of overflows. In southerly district, on the Cuyahoga River, tanks and sprinkling filters are required. With money available partial projects are recommended, providing coarse screens and grit chambers with Cl disinfection on the lake, and in addition Imhoff tanks on the river. LANGDON PEARSE.

Extra-cantonment zone sanitation. W. A. HARDENBERGH. *Munic. J.* 45, 421-5, 450-2(1918).—A description of the activities of the U. S. Public Health Service at Camp Bowie and vicinity in anti-malarial work. Privies were cleaned up in both urban and rural surroundings.

## 15. SOILS, FERTILIZERS AND AGRICULTURAL POISONS.

J. J. SKINNER.

**Influence of the mechanical composition of the soil on the availability of nitrate of soda and dried blood.** J. G. LIPMAN AND A. W. BLAIR. New Jersey Agr. Exp. Sta., *Rpt. Dept. Soil Chem. and Bact.* 1917, 336-68.—A continuation of work begun in 1911 (cf. C. A. 11, 1873). In these cylinder expts. barley and buckwheat were grown, the fertilizers being added to the first crop. The yield of barley was higher with  $\text{NaNO}_3$  than with dried blood. For the barley crop the av. recovery of N from  $\text{NaNO}_3$  was 60.53% and from dried blood 30.98%. The highest recovery from  $\text{NaNO}_3$  was 69.8% and from dried blood 41.1%. For the 2nd crop, buckwheat, the dried-blood cylinders gave the higher yield.  $\text{NaNO}_3$  produced no increase over the check. In the combined recoveries  $\text{NaNO}_3$  stands first in all series, the av. being 62.29% for  $\text{NaNO}_3$  and 42.5% for dried blood. From the results secured over a period of years it is shown that  $\text{NaNO}_3$  has little or no residual effect. Dried blood shows some residual effect. The initial effect of  $\text{NaNO}_3$  on these soils is more valuable than the total effect of dried blood.

J. J. SKINNER.

**The question of lime fertilizing.** E. TRUNINGER. *Mitt. Lebensm. Hyg.* 9, 288-9 (1918).—The degree of fineness and the amt. of limestone used had very little influence on the growth of oats. With red clover and carrots the finest limestone (0.1 mm. diam.) had a deleterious effect, while the larger sizes of limestone (2.0 mm. diam.) had a beneficial effect. This was very marked with the carrots.

H. E. WOODWARD.

**Ammoniacal liquor as a fertilizer.** F. MACH. *J. Ind. Eng. Chem.* 11, 156(1919).—A note on the results of work at the Agr. Institute, Baden. While good results are obtained with this by-product, it should be applied and ploughed under about 2 weeks before seeding the soil to avoid toxic effects of phenols,  $\text{H}_2\text{S}$ , HSCN, and HCN, which accompany the  $\text{NH}_3$ .

R. B. DEEMER.

**Valuation of fertilizers.** J. A. MURRAY. *J. Soc. Chem. Ind.* 37, 317-87(1918).—A criticism of the old "unit" system of price valuation of fertilizers which though simple fails to take into account the cost of production and value to the farmer. Formulas are given for more correct valuation and discussed in detail.

R. B. DEEMER.

**Fertilizer experiments with spoilt calcium cyanamide.** M. POPP. Oldenburg. *Mitt. deutsch. Landw. Ges.* 32, 776-80(1918); *Biedermanns Zentr.* 47, 299-307(1918); cf. C. A. 11, 1241.—The slight fertilizing action of old  $\text{CaCN}_2$ , obtained in previous expts. is attributed to chem. decompn. with the formation of dicyanodiamide. Samples of a lot of unbagged  $\text{CaCN}_2$  in storage were kept in cork-stoppered glass bottles. Analyses of these samples (a) taken in 1913, (b) in 1914, (c) in 1915 were made using Hager and Kern's method for the detn. of dicyanodiamide, with results as follows: Total N of the original samples: (a) 15.06, (b) 14.32, (c) 12.47%. In 1917 total N, cyanamide N and dicyanodiamide N, resp.: (a) 13.69, 2.45, 7.04; (b) 12.81, 1.21, 5.98; (c) 12.15, 1.19, 6.79%. The diminished % of total N is explained by the absorption of  $\text{H}_2\text{O}$ .  $\text{H}_2\text{O}$  also dissolved  $\text{CaCN}_2$ , which was decomposed into dicyanodiamide and urea. The results of pot expts. comparing  $\text{CaCN}_2$ ,  $\text{NH}_4\text{Cl}$ , urea and urea nitrate are reported. Both fresh and old  $\text{CaCN}_2$  were used and the effect of the addition of bog iron ore and Mn slag was investigated. The oat crop used 59-68% of the N in fresh  $\text{CaCN}_2$  and only 26% of that in old  $\text{CaCN}_2$ . Neither bog iron ore nor manganese slag showed any noteworthy effect. Old  $\text{CaCN}_2$  containing much dicyanodiamide caused a high N content in the straw. The expts. show that a  $\text{CaCN}_2$  with about 6.5% dicyanodiamide caused injury to the plants cultivated when used in quantities of 90 kg. per hectare.

ALBERT R. MERZ.

**Effects of certain alkali salts on ammonification.** P. E. BROWN AND D. R. JOHNSON. Iowa Agr. Expt. Sta., *Research Bull.* 44(1918).—A study was made of the effect of the alkali salts,  $\text{Na}_2\text{CO}_3$ ,  $\text{NaHCO}_3$ ,  $\text{Na}_2\text{SO}_4$ , and  $\text{NaCl}$ , on ammonification in the presence and in the absence of  $\text{CaCO}_3$ . When used alone  $\text{CaCO}_3$  was found to exert a marked beneficial influence on ammonification. The greatest effect occurred with 0.3%, but up to 5.0% no decrease occurred. The alkali salts tested were found to exert a stimulating effect when used alone at very low concns. Thus, with  $\text{Na}_2\text{CO}_3$  a stimulating effect was observed at a concn. of 0.1%; with  $\text{NaHCO}_3$  at 0.05%; with  $\text{Na}_2\text{SO}_4$  at 0.1%; and with  $\text{NaCl}$  at 0.005%. Increased additions of these salts, however, failed to stimulate the ammonifiers but on the contrary retarded their action. For the soil used the point of toxicity was between 0.1% and 0.2% for  $\text{Na}_2\text{CO}_3$ ; between 0.05% and 0.1% for  $\text{NaHCO}_3$ ; between 0.1% and 0.5% for  $\text{Na}_2\text{SO}_4$ ; and between 0.005% and 0.01% for  $\text{NaCl}$ . Increasing additions of all these salts brought about gradually increasing depressions in ammonification. When  $\text{CaCO}_3$  was used with these salts it was found to reduce their toxicity to a considerable extent in every case, and in some instances made the toxic amts. of the salts actually stimulative to ammonification. Various combinations of the alkali salts were observed to exhibit a greater toxic effect than the same salts in the same concn. exhibited individually. The results obtained in greenhouse expts. confirmed the conclusions arrived at from lab. tests.

W. H. ROSS.

**Vegetative experiments on the availability of phosphorus and potassium compounds.** J. G. LIPMAN AND A. W. BLAIR. New Jersey Agr. Exp. Sta., *Rpt. Soil Chem. and Bact.* 1917, 353-68.—In these expts. testing several sources of phosphate, soybeans were grown in sand in earthenware pots. Basic slag and acid phosphate had about the same crop-producing power. Blue rock phosphate had practically no effect, and brown rock gave only a slight increase. The av. N content of the crop grown with basic slag was about equal to that with acid phosphate; it was less with raw rock phosphate. Greensand marl used as a source of K gave increased yields in a coarse, white sand. In a coarse sand containing 1.09% total  $\text{K}_2\text{O}$  applications of marl did not increase the growth of oats and buckwheat; it increases slightly the growth of barley. The % of  $\text{K}_2\text{O}$  in dry matter of soy beans from pots treated with sol.  $\text{K}_2\text{O}$  was higher than in that from marl-treated pots or the check pots, the yield of dry matter was not increased. The N content of the soy beans from the different pots was not widely different. "Soy beans when inoculated and supplied with lime and sol. phosphates can make a good growth and accumulate a high % of N up to the time the pods are half filled without the aid of readily sol. K compds."

J. J. SKINNER.

**Experiments on the value of greensand as a source of potassium for plant culture.** RODNEY H. TRUE AND FRED. W. GEISE. Dept. Agr. *J. Agr. Research* 15, 483-92 (1918).—It has been shown by pot expts. carried out with crushed quartz and Shive's three-salt nutrient soln. (C. A. 9, 2396) as a basis that greensands and greensand marls from Virginia and New Jersey are able to supply sufficient K to satisfy the demand of Turkey Red wheat and red clover during the first 2 months of their growth. This enables them to make a greater dry weight of tops than was seen in similar cultures in which the K demand was supplied by  $\text{KCl}$ ,  $\text{K}_2\text{SO}_4$ , and  $\text{K}_3\text{PO}_4$ . The results are thus thought to indicate that by the use of greensand sufficient K is rendered promptly available to meet the needs of many, perhaps most, farm crops. An exception was noted in the case of a greensand from Courtland, Va., which seemed to have a toxic effect on plants. Marls of this class, however, are very seldom encountered.

W. H. ROSS.

**Effects of farm manure in stimulating the yields of irrigated field crops.** C. S. SCOFIELD. Bur. Plant Ind. *J. Agr. Research* 15, 493-503(1918).—The effect of

manure on the yields of Irish potatoes and sugar beets under irrigation has been tested for 6 years in 7 rotations at each of 3 different stations in the northern Great Plains. Comparison was made between the yields of these crops when grown in rotations without manure and when grown in the same sequence in other rotations in which manure was applied at the rate of 12 tons per acre once during the cycle of the rotation. The results show that the effect of the manure at the 3 stations has been to increase the yield of potatoes about 40, 34 and 26 bushels per acre, resp.; to increase the proportion of marketable potatoes about 8, 7 and less than 1%, resp.; and to increase the yield of sugar beets 4.3, 1.9 and 2.6 tons per acre without materially affecting the sugar content of the beets. In 5 of the 7 rotations considered the increased yields were from the crop immediately following the application of the manure. In the other 2 rotations the yields were from crops produced the second season after the manure was applied. The increases in yield shown in these 2 cases, as well as the effects observed with other crops grown in these rotations, show that the benefit of the manure is appreciable for 2 years or more after it is applied.

W. H. Ross.

**Relation of inorganic soil colloids to plowsole in citrus groves in southern California.** CHARLES A. JENSEN. *Bur. Plant Ind. J. Agr. Research* 15, 505-19(1918).—A hard soil layer termed "plowsole" usually forms immediately under the soil mulch in cultivated citrus groves in southern California. After being broken up with a subsoiler it reforms when cultivation is resumed. It does not form in mulched basins, nor seriously in groves surface-mulched with organic matter and seldom cultivated. An examn. of soil samples collected from (1) the soil mulch, (2) the plowsole crust, and (3) the subsoil under the plowsole in each of 8 orange groves in which plowsole occurred showed that no accumulation of water-sol. Fe, Ca, Mg or  $\text{SiO}_2$  in the plowsole layer could account for its formation; that no greater accumulation of total  $\text{NH}_3$ -sol.  $\text{SiO}_2$ , Fe, Al or  $\text{P}_2\text{O}_5$  was found in the plowsole than in the soil mulch or in the subsoil; and that there was an accumulation of  $\text{NH}_3$ -sol. colloidal  $\text{SiO}_2$ , Fe and Al in the plowsole but not of colloidal  $\text{P}_2\text{O}_5$ . A study was accordingly undertaken of the inorganic material of a soil remaining in suspension in water, "colloidal suspension," at the end of 24 hrs. after the soil had been treated in a specified way. It was found that the plowsole contained a markedly higher percentage of inorganic colloid suspension than the soil mulch and usually higher than the subsoil. The addition of ground lime, S, and gypsum decreased, and  $\text{NaNO}_3$  increased the percentage of inorganic colloid suspension in the soil. Organic matter had the effect of counteracting the action of the lime and the  $\text{NaNO}_3$ , but not of the S or the gypsum. The compn. of the colloid suspension obtained from the soil was not affected by the addition of lime, S,  $\text{NaNO}_3$ ,  $\text{FeSO}_4$ ,  $(\text{NH}_4)_2\text{SO}_4$  or organic matter. The addition of gypsum, however, increased the percentage of  $\text{SiO}_2$ , Ca, Mg and decreased the percentage of Fe in the colloid suspension. The suspension was also found to contain a higher percentage of Fe, Al and Mn than the untreated soil, and the percentage of Fe and Al in colloid suspension from soils which readily form hard plowsole is higher than in the suspension from soils in which this is not formed. It is considered, therefore, that the percentage of Fe and Al in the colloid suspension from a soil is directly correlated with the readiness with which it forms plowsole.

W. H. Ross.

**The potash and lime requirements of legumes.** CLAUSEN. Heide (Holst.). *Illust. Landw. Ztg.* 37, 547-9(1917); *Biedermanns Zentr.* 47, 313-8(1918); cf. *Illust. Landw. Ztg.* 33, 910-1(1913).—Expts. were carried out with peas on a loamy sand soil and a pure sand soil both with and without the addition of marl. N fertilization paid only upon the unlimed loamy sand soil. Thomas slag meal was more effective on the limed soils.  $\text{K}_2\text{O}$  (as kainite) was advantageous wherever used. The addition of 5000 kg. marl per hectare gave increased yields (with one exception). This was especially

true upon the loamy soil because of the loosening and aerating effect of the added marl.

ALBERT R. MERZ.

Fertilization experiments with tobacco in 1915 and 1916. E. SIDENIUS. *Proefstation voor Vorstenlandsche Tabak Mededeeling* 26, 1916; Semarang (Java); *Biedermanns Zentr.* 47, 318-20(1918).—A continuation of expts. conducted in 1913-5 by deVries (*Biedermanns Zentr.* 1915, 533).  $(\text{NH}_4)_2\text{SO}_4$  gave not only increased yields but caused an improvement in quality of the tobacco and increase in length of the leaves. There is also a slight decrease in combustibility which was, however, of no practical importance. Stable manure caused inferior combustibility. This is ascribable to the Cl content of the manure.

ALBERT R. MERZ.

The corrosion of beet seeds with sulfuric acid. O. FALLADA. *Oesterr.-ung. Z. Zuckerind.* 1917, 22; *Biedermanns Zentr.* 47, 324-5(1918).— $\text{H}_2\text{SO}_4$  of 60° Bé. cannot replace concd.  $\text{H}_2\text{SO}_4$  in the Hiltner process for the corrosion of beet seeds to promote the rapidity of their germination. A 53° acid gave satisfactory results when the corrosion was conducted according to H. Mucha's modification in which the drum used is preheated with steam and the duration of action of the acid is extended to 2 1/2 hrs.

ALBERT R. MERZ.

The effect of certain organic substances on seed germination. E. B. FRED. *Soil Science* 6, 333-49(1918).—By means of pot expts. using Miami silt loam it was found that nitrogenous substances such as alfalfa powder, casein, and peptone do not seriously injure seed germination unless used in very large quantities. There was a decided decrease in germination of cottonseed when these substances were used in amts. greater than 0.5%.  $\text{CaCO}_3$  does not lessen the decrease in germination due to very large applications of alfalfa powder or casein. Sugar greatly increases bacterial growth and retards the rate of seed germination. The % of germination was decreased in amts. larger than 1%. In the presence of 5% of sugar all the seedlings were killed. The retarding action of sugar is probably due to the large amts. of  $\text{CO}_2$  given off in the decomposition of the sugar. Soil sterilization was found to inhibit the rate of seed germination.

J. J. SKINNER.

The effect of a humus-containing brown coal as a preservative of liquid manure. O. LEMMERMANN AND H. WEISSMANN. Berlin. *Mitt. deutsch. Landw. Ges.* 32, 741-3 (1917); *Biedermanns Zentr.* 47, 307-11(1918).—Lignite from near Sommerfeld was able to bind 5.12%  $\text{NH}_3$  while a peat could only fix 1.98%. Expts. showed that the coal added in quantities of 50 to 60% could preserve even strongly fermented liquid manures. Fertilizer expts. with the liquid thus treated showed an excellent effect which exceeded the effect of  $(\text{NH}_4)_2\text{SO}_4$  added in corresponding amts. The large amt. of brown coal necessary is a drawback to its use for this purpose.

ALBERT R. MERZ.

Manuring of *Hevea brasiliensis*. R. D. ANSTRAD. *Agr. J. India* 13, 661-5 (1918).—Some of the most successful results in South India in manuring rubber trees have been obtained from the use of lime and manure. Expts. are cited in which lime produced 2.15 lbs. of made rubber per tree, lime and manure 2.44 lbs., against 2.34 lbs. for the untreated tree. In another expt. lime gave a production of 2.37 lbs. per tree and  $\text{NaNO}_3$  only 2.05 lbs. The most successful rubber production was secured where lime was used in amts. of 1000 lbs. per acre and a green manure crop turned under annually. An expt. conducted in Ceylon is cited where P fertilizers gave best results and K the poorest. N produced a large increase after the first application, but a decrease in the following years when the same application was repeated. The cause of the failure of fertilizer expts. with rubber trees in general is discussed.

J. J. SKINNER.

Report Rothamstead experiment station 1915-17. E. J. RUSSELL. 71 pp. A rept. of the work which gives a summary of papers published in scientific journals.

A guide to the expt. plots is given, with tables appended giving the yields in 1915-'16-'17 of the various fertilizer plots conducted at the station. J. J. SKINNER.

Potash salts in the United States (ANON.) 18. Widening demand for blast-furnace slag (WRIGHT) 9. Lead arsenate (Brit. pat. 121,101) 18.

WERY, GEORGES: *Les établissements scientifiques de recherches agricoles en France et à l'étranger.* Paris: Société l'encouragement pour l'industrie nationale. 164 pp. For review see *Rev. sci.* 56, 753(1918).

Fertilizers; insecticides. G. TRUFFAUT. Brit. 120,288, Dec. 3, 1917. A compn. for application to soil to act as a fertilizer and insecticide consists of CaS, heavy tar oils or hydrocarbons which have been treated with alk. solns. to remove phenols, cresols, etc., and with acids such as  $H_2SO_4$ , to remove bases, crude  $CaSO_4$ , and  $Ca_3(PO_4)_2$ .

## 17. PHARMACEUTICAL CHEMISTRY.

W. O. EMERY.

Review of the American patent literature on arsphenamine (salvarsan) and other arsenicals. H. L. LEWIS. *J. Ind. Eng. Chem.* 11, 141-5(1918). W. O. E.

Effect of heating opium on its morphine content. H. E. ANNETT AND H. SINGH. *J. Soc. Chem. Ind.* 37, 315-7T(1918).—Samples of opium heated in a  $H_2O$  oven at  $97-8^\circ$  may suffer a large decrease in morphine content. No such loss, however, was observable during the first 5 days' heating, and hence this treatment can hardly affect results obtained by the B. P. method. Opium, when heated in the  $H_2O$  oven, suffers a marked change in its physical properties. W. O. E.

Lead in pharmaceutical zinc oxide. W. D. COLLINS AND W. F. CLARKE. *J. Ind. Eng. Chem.* 11, 138-9(1918).—"For a short time after the beginning of the war it was not possible to procure ZnO of the U. S. P. standard produced in the U. S. The U. S. P. test for heavy metals will not detect less than 0.05% of Pb in ZnO. It is possible at the present time to obtain ZnO which, with respect to the presence of Pb, is of much higher quality than is called for by the requirements of the U. S. P." W. O. E.

Estimation of phenacetin and other *p*-aminophenol derivatives by hypochlorous acid. A. D. POWELL. *Analyst* 44, 22-5(1919).—The method is based on the reaction obtaining between a hypochlorite (Cl) and a salt of *p*-aminophenol, as:  $HOC_6H_4NH_2 \cdot HCl + 4Cl = O:C_6H_4NCl + 4HCl$ , the soln. containing the quinone chlorimine being thereupon freed from Cl, KI added, and the 4 atoms of I liberated by a reverse of the reaction just given then titrated with 0.1 *N*  $Na_2S_2O_3$ . In the case of metol (methyl-*p*-aminophenol sulfate), it should be noted that, owing to the presence of the Me in the  $NH_2$  group, no chlorination of the latter takes place, although a quinone deriv. is formed, as:  $HOC_6H_4NHCH_3 + 2Cl = O:C_6H_4NCH_3 + 2HCl$ . Since it was found best to remove free Cl (due to excess of hypochlorite) by blowing a stream of air through the soln., a correction was necessary on account of the slight volatility of chlorimine and also for the action of dissolved air on the iodide, such correction averaging 1.5% of the total quinone chlorimine present for an aeration of 15-20 min. *Estimation of p-aminophenol, p-phenetidine, etc.*: An amt. of an acid soln. equiv. to about 0.1 g. of the base is measured into a 250-cc. stoppered bottle and diluted to rather more than 100 cc., 5 cc. strong HCl are added, followed by 10 cc. of NaOCl soln. (about

0.8 N). The resulting soln. should be pure yellow and not deposit yellow flocks. Air is now blown through at a brisk rate for 15 min., 2.5 g. of KI are added, and the soln. is allowed to stand for at least 15 min. The liberated I is then titrated with 0.1 N  $\text{Na}_2\text{S}_2\text{O}_3$  (1 cc. = 0.00273 g. *p*-aminophenol or 0.00343 g. *p*-phenetidine) and starch indicator. The result is multiplied by the factor 1.015 to correct for loss during aeration. *Estimation of phenacetin.*: One g. of phenacetin is boiled for 2 hrs. with a mixt. of 25 cc. strong HCl (1.16) and 15 cc. of  $\text{H}_2\text{O}$  in a small flask fitted with an air condenser. After cooling, the soln. is diluted to some definite vol., and an aliquot representing 0.2 g. phenacetin taken for the estn. exactly as above. One cc. 0.1 N  $\text{Na}_2\text{S}_2\text{O}_3$  = 0.00448 = phenacetin. In the presence of caffeine citrate, the results obtained were slightly high. In admixt. with salol, hydrolysis was first effected with 10% NaOH soln. followed by treatment with boiling strong HCl. After removal of salicylic acid and phenol with  $\text{Et}_2\text{O}$ , the chlorination and titration were carried out in the usual manner. Mixtures of phenacetin and acetanilide cannot be analyzed without first removing the latter. Estn. of other *p*-aminophenol derivs. as lactophenin and salophen were effected in exactly the same way as phenacetin. The basic reaction above indicated for true metol (methyl-*p*-aminophenol sulfate) involving the liberation of only 2 atoms of I provides a simple means of distinguishing between that product and its "substitutes," since all of the latter examd. were found to be either *p*-aminophenol or *p*-aminocresol salts.

W. O. E.

*Preparation of sodium salicylate and sodium theobrominate.* G. DALL'ACQUA. *Boll. chim. farm.* 57, 201-2 (1918).—For each kg. of diuretin there are required 442 g. of Na salicylate and this may be prepd. by the reaction of 381.20 g. salicylic acid and 232 g.  $\text{NaHCO}_3$ . For the prepn. of the corresponding amt. of Na theobrominate 110.5 g. NaOH free from carbonate are dissolved in an equal wt. of boiled distd.  $\text{H}_2\text{O}$  and thoroughly mixed with 497.2 g. theobromine previously moistened with approx. 150 cc. abs. alc. or alc. distd. over NaOH. When the mass is almost entirely cooled it is intimately mixed with the Na salicylate after it has been ascertained that the latter does not yield  $\text{CO}_2$  when treated with dil. acid. The mixt. may be readily dried to a pulverulent mass containing about 10%  $\text{H}_2\text{O}$  and the latter may be removed by prolonged heating if desired. The yield is practically theoretical and the product complies with the required tests. A mixt. of  $\text{AcONa}$  and Na theobrominate may be prepd. in a similar manner.

H. S. PAINE.

*Chemical evaluation of digitalis.* A. TSCHIRCH AND F. WOLTER. *Univ. Bern. Schweiz. Apoth. Ztg.* 56, 469-74, 495-8, 512-4 (1918).—Present physiol. methods define only the poison, not the therapeutic value of digitalis, and this in the frog only. Chem. evaluation hitherto has not always represented the true active principles; thus, *e. g.*, digitoxin (pseudodigitoxin, Tschirch), usually resulting in chem. assay, is not a uniform substance, and gitalin, the carrier of the sp. digitalis effect (Focke, Tschirch), is not detd. at all in Keller's method. After comparing the methods of Keller, Reed and Vanderkleed, Stoeder, Burmann and Martindale as to their yield in glucosides and the physiol. activity of the latter, a new method is proposed, based on that of Keller. Ext. the leaves first with  $\text{Et}_2\text{O}$ , removing chlorophyll, fat and resins. Distil off the  $\text{Et}_2\text{O}$ , ext. the leaves with abs. EtOH and purify as usual with  $\text{Pb}(\text{OAc})_2 \cdot \text{PbO}$ . A colorless liquid results. In now extg. the glucosides,  $\text{CHCl}_3$  is replaced by acetone, which is found to be the best solvent for the active principles of digitalis. It dissolves gitalin, digitoxin and digitalin Boehringer; digitalin Merck and digitonin are insol. By adding NaCl to the aq. acetone soln. the inert aq. layer is sepd. The evapn. residue of the acetone contains all the active principles of digitalis, called *pandigilon*. Its physiol. activity was found to be 1.2 mg. per g. of frog wt., while direct extn. of the leaves gave a much more active residue, 0.47 mg. The discrepancy is unaccounted for;

the intermediate fluids and ppts. are inert. This and some special expts. support Ziegenbein's observation that pseudodigitoxin isolated from a given wt. of dried leaves, was from 2.6 to 6.6 times less active than the leaves themselves. T. contends that the active principles of digitalis are held in soln. by the aid of other substances, which enhances their activity by mutual influence. While the new method yields practically all active digitalis principles, and in a purer state than obtained by other methods, no relation has been found to exist between the chem. and physiol. values of digitalis leaves. S. WALDBOTT.

**Sulfopinol, a substitute for unguentum sulfuratum compositum.** ANON. *Svensk Farm. Tid.* 1918, 361; *Schweiz. Apoth. Ztg.* 56, 517(1918).—Take of liquid pitch 150 g., pure KOH, 16; wheat starch, 75; sublimed S, 150; H<sub>2</sub>O to make 1000 g. Boil the wood tar with KOH and a little H<sub>2</sub>O until completely saponified; dissolve the tar soap in warm H<sub>2</sub>O. Add the starch previously triturated with cold H<sub>2</sub>O, heat again until a paste is obtained. Allow to cool and add the S. Sulfopinol has the consistency of a viscous liniment, and has been applied with success in a Stockholm hospital. S. W.

**Table of national pharmacopeias.** C. BUHRER. *Schweiz. Apoth. Ztg.* 56, 515-7 (1918).—A list of the various editions, with dates, of the pharmacopeias official in different countries. Taken from Bruntz et Jaloux, *Les plantes officinales*. S. W.

**Permanent and resorbable corrosive sublimate pills.** ANON. *Union pharm.* 1917, 6; *Schweiz. Apoth. Ztg.* 56, 484-5(1918).—Take of HgCl<sub>2</sub> 1 g., powdered opium 1 g., licorice powder 5, mass of gum 3.2 g. Divide into 100 pills. To obtain the mass of gum, allow 1 g. of powdered gum tragacanth and 1 g. of gum arabic to swell in 10 g. of warm glycerol. The powders are then incorporated in this excipient. In this form, the HgCl<sub>2</sub> is partly dissolved in glycerol, and intimately mixed with colloidal substances which swell gradually in contact with the digestive juices. Thus it is brought into soln. gradually, without irritating the stomach or the intestines. Besides, in this combination it does not undergo any harmful chem. change. S. WALDBOTT.

**Action of Dakin's solution on catgut and silk.** D. CHEVRIER. *Bull. soc. pharm. Bordeaux; Schweiz. Apoth. Ztg.* 56, 474(1918).—Dakin's soln. containing 0.5% hypochlorite, after 3 hrs. contact, causes catgut to swell, later to gelatinize and dissolve. Silk undergoes similar changes, hence the danger in applying Dakin's soln. in the method of Carrel to the first dressing following a surgical operation, owing to the powerful proteolytic properties of the soln. S. WALDBOTT.

**Retrogression of Dakin's solution when in contact with caoutchouc.** D. CHEVRIER. *Schweiz. Apoth. Ztg.* 56, 498(1918).—Rubber tubing in contact with Dakin's soln. caused, after 12 hrs., an 8.5 and 8.7% reduction in the titer of Cl in 2 cases, and of 33.3% in the case where old tubing was used. S. WALDBOTT.

**Official standard for caffeine sodio-benzoate.** A. B. LYONS. *J. Am. Pharm. Assoc.* 7, 1029-30(1918).—The U. S. Pharmacopeia permits a variation of from 46 to 50% in the caffeine content of this salt. The discussion indicates that a range of from 47.3 to 48% of anhydrous caffeine is amply sufficient. L. E. WARREN.

**The effect of alcohol on pituitary extract.** H. C. HAMILTON. *J. Am. Pharm. Assoc.* 7, 1030-1(1918).—Pituitary preps. containing more EtOH than could possibly be present from washing the syringe or the site of injections with EtOH, were diluted and tested by the usual method. The activity was unlessered. From a series of expts. H. concludes that the only action between EtOH and pituitary exts. is a precipitant one if the solvent be in very great excess. L. E. WARREN.

**Dry tuberculin preparation.** E. HELBIG. U. S. 1,288,582, Dec. 24. A dry tuberculin prepn. suitable for making injection liquids is prepd. by mixing concd. tuberculin with about an equal weight of dehydrated borax. Glycerol, NaCl and milk sugar may be included in the mixt. and it may be formed into tablets.

**Synthetic drugs.** ROCKEFELLER INSTITUTE FOR MEDICAL RESEARCH. Brit. 120,383, Oct. 3, 1918. Aromatic arsonic acids, containing an  $\alpha$ -aminoacylarylamide group  $\text{—NH.CHR.CONR'R''}$  ( $R = H$ , alkyl, or aryl,  $R'$  and  $R'' = H$  or aryl), are prepd., (1) by treating  $p$ -aminophenylarsonic acid, or homologs, isomers, or substitution products thereof, or their salts, with an  $\alpha$ -haloacylarylamide, (2) by treating an ester of a phenylglycinearsonic acid with an arylamine. Examples are given of the prepn. of phenylglycinanilide- $p$ -arsonic acid from  $p$ -aminoglycinanilide- $p$ -arsonic acid from  $p$ -aminophenylarsonic acid and  $\alpha$ -iodoacetanilide (or the corresponding bromo- or chloroacetanilide) and from the methyl ether of phenylglycine- $p$ -arsonic acid and aniline and of phenylglycyl- $m'$ -aminophenol- $p$ -arsonic acid from  $p$ -aminophenylarsonic acid and  $m$ -chloroacetylaminophenol. The following products also are specified: phenylglycine- $p$ -arsonic acid- $o'$ -toluidide,  $-m'$ -toluidide,  $-p$ -toluidide,  $\alpha$ -naphthalide,  $-\beta$ -naphthalide- $p'$ -chloroanilide,  $-p'$ -iodoanilide,  $-p'$ -nitroanilide,  $-p'$ -aminoanilide,  $-p'$ -acetaminoanilide,  $-p'$ -uraminoanilide,  $-4'$ -methyl-5'-uraminoanilide,  $-m'$ -oxamylaminoanilide,  $-p'$ -oxamylaminoanilide,  $-p'$ -hydroxyanilide,  $-4'$ -hydroxy- $\alpha$ -naphthalide,  $-p'$ -methoxyanilide,  $p$ -arsonic acid of phenylglycyl- $o'$ -aminophenoxyacetamide,  $-p'$ -aminophenoxyacetic acid,  $-p'$ -aminophenoxyacetamide,  $-p'$ -aminophenoxyacetylurea,  $-3'$ -methyl-4'-aminophenoxyacetic acid,  $-\text{anthranilic acid}$ ,  $-\text{anthranilic ethyl ester}$ ,  $-N$ -methylantranilic acid,  $-\text{anthranilamide}$ ,  $-m'$ -aminobenzamide,  $-m'$ -aminobenzoylurea,  $-p'$ -aminobenzamide,  $-5$ -aminosalicylamide,  $-m'$ -aminobenzenesulfoneamide,  $-\text{sulfanilic acid}$ ,  $-p'$ -aminobenzenesulfonamide,  $-p'$ -aminophenylarsonic acid,  $-m'$ -aminophenylacetamide,  $-p'$ -aminophenylacetamide,  $-p'$ -aminophenylacetylurea,  $-p'$ -aminoacetophenone, 4-arsonic acid of 2-methylphenylglycyl-3'-aminophenol, 4-arsonic acid of 2-methylphenylglycyl-4'-aminophenol,  $p$ -arsonic acids of phenyl- $\alpha$ -phenylglycyl- $m'$ -aminophenol,  $-p'$ -aminophenylurea,  $-m'$ -aminobenzamide,  $-p'$ -aminophenylacetamide. Sol. salts are prepd. by treating the products with NaOH, etc.

**Synthetic drugs.** ROCKEFELLER INSTITUTE FOR MEDICAL RESEARCH. Brit. 120,384, Oct. 3, 1918. Aromatic arsenoxides containing an  $\alpha$ -aminoacylamide group  $\text{—NH.CHR.CONR'R''}$  ( $R, R'$ , and  $R'' = H$ , alkyl, or aryl), are prepd. (1) by treating the arsonic acids described in 120,381 and 120,383 with mild reducing agents, *e. g.*,  $\text{SO}_2$  in the presence of HI, (2) by treating aminophenylarsenoxides with  $\alpha$ -haloacyl-

amides. Examples are given of the prepn. of phenyl-*p*-arsenoxide- $\alpha$ -phenylglycinamide by reducing the corresponding arsonic acid, phenyl-*p*-arsenoxideglycinanilide by condensing *p*-aminophenylarsenoxide with  $\alpha$ -chloroacetylaniine, phenyl-*p*-arsenoxideglycyl-*m'*-aminophenol and phenyl-*p*-arsenoxideglycylanthranilic acid by reduction of the corresponding arsonic acids. The following products are also specified: *p*-arsenoxides of phenylglycyl-*p'*-aminophenol, -*m'*-aminobenzenesulfonamide, -*p'*-aminobenzenesulfonamide, -sulfanilic acid, and of *o*-tolylglycyl-4'-aminophenol.

**Synthetic drugs.** ROCKEFELLER INSTITUTE FOR MEDICAL RESEARCH. Brit. 120,385, Oct. 3, 1917. Arsenoaryl compds. containing in each aromatic nucleus an  $\alpha$ -aminoacylarylamide group are prepd. by treating with strong reducing agents the corresponding arsonic acids or arsenoxides, described in 120,383 and 120,384 (*supra*). Examples are given of the prepn. of *p*-arsenophenylglycinebis-*m'*-hydroxyanilide by reducing the *p*-arsonic acid of phenylglycyl-*m'*-aminophenol with hypophosphorus acid in the presence of HI, or by reducing the corresponding arsenoxide with hypophosphorus acid alone. The following products also are specified: *p*-arsenophenylglycinebis-*p'*-hydroxyanilide, 4-arsenophenylglycinebis-3'-carboxamido-4'-hydroxyanilide, *p*-arsenophenylglycinebis-*m'*-sulfonamidoanilide, *p*-arsenophenylglycinebis-*p'*-hydroxyanilide. The products containing salt-forming groups (OH, HOCO, SO<sub>3</sub>H, etc.) are sol. in aq. alkalis.

**Synthetic drugs; intermediate products.** N. NAGAI. Brit. 120,936, July 13, 1917. 1-Phenyl-2-nitro-1-propanol (*a*) is prepd. by condensing BzH with nitroethane in the presence of weak inorg. or org. bases. 1-Phenyl-2-(methylamino)-1-propanol is obtained by reducing (*a*) in the presence of HCHO by means of Zn and HOAc; the acetate formed is converted into the hydrochloride. The product is isomeric with the known ephedrine and resembles them in its pupil-dilating properties.

**Synthetic drugs.** ROCKEFELLER INSTITUTE FOR MEDICAL RESEARCH. Brit. 120,381, Oct. 3, 1918. Aromatic arsonic acids containing an  $\alpha$ -amino acylamide group NH.CHR.CONR'R' (R = H, alkyl, or aryl, R' = H, benzyl, or substituted benzyl) are prepd. (1) by treating *p*-aminophenylarsonic acid, or its isomers, homologs, or substitution products, or salts thereof, with an  $\alpha$ -haloacylamide; (2) by treating the esters of phenylglycinearsonic acids with NH<sub>3</sub> or an amine. Examples are given of the prepn. of phenylglycinamide-*p*-arsonic acid from *p*-aminophenylarsonic acid and chloroacetamide, or from methyl phenylglycine-*p*-arsonate and NH<sub>3</sub>, and of the  $\alpha$ -phenyl deriv. thereof from *p*-aminophenylarsonic acid and phenylchloroacetamide. The following products are also specified: phenylglycinamide-*o*- and -*m*-arsonic acids, phenylglycinemethylamide-*m*- and -*p*-arsonic acids, phenylglycinethylamide-*p*-arsonic acid, phenylglycinepropylamide-*p*-arsonic acid, phenylglycinedimethylamide-*p*-arsonic acid, phenylglycinediethylamide-*p*-arsonic acid, phenylglycinepiperidide-*p*-arsonic acid, phenylglycinebenzylamide-*p*-arsonic acid, phenylglycine-*m'*-carboxamidobenzylamide-*p*-arsonic acid, phenylglycine-*p'*-acetaminobenzylamide-*p*-arsonic acid, phenylglycine-*m'*-carboxureidobenzylamide-*p*-arsonic acid, phenylglycine-*p*-uraminobenzylamide-*p*-arsonic acid, phenyl- $\alpha$ -aminopropionamide-*p*-arsonic acid, and the glycinamides of amino-*o*-tolyl-*p*-arsonic acid and amino-*m*-tolyl-*p*-arsonic acid. Sol. salts are prepd. by treating the products with alkalis, alkali carbonates, or NH<sub>3</sub>.

**Synthetic drugs.** ROCKEFELLER INSTITUTE FOR MEDICAL RESEARCH. Brit. 120,382, Oct. 3, 1918. Aromatic arsonic acids, containing an  $\alpha$ -aminoacylurea group -NH.CHR.CONHCONHR' (R = H, alkyl, or aryl, R' = H, alkyl, aryl, or aralkyl) are prepd. by treating *p*-aminophenylarsonic acid, or its isomers, homologs, or substitution products, or salts thereof, with  $\alpha$ -halogenacylureas XCHRCONHCONHR' (X = halogen). Examples are given of the prepn. of phenylglycineureide-*p*-arsonic

acid from *p*-aminophenylarsonic acid and  $\alpha$ -chloroacetylurea, phenylglycine- $\beta$ -methylureide-*p*-arsonic acid from *p*-aminophenylarsonic acid and  $\alpha$ -chloroacetyl- $\beta$ -methylurea, and phenyl- $\alpha$ -phenylglycineureide-*p*-arsonic acid from *p*-aminophenylarsonic acid and  $\alpha$ -phenyl- $\alpha$ -chloroacetylurea. The following products also are specified: phenylglycinethylureide-*p*-arsonic acid, phenyl- $\alpha$ -aminopropylurea-*p*-arsonic acid, phenylglycinebenzylureide-*p*-arsonic acid, phenylglycinebenzylureide-*p*-arsonic acid, *o*-tolylglycineureide-*p*-arsonic acid, *o*-tolylglycinemethylureide-*p*-arsonic acid, phenylglycinemethylureide-*m*-arsonic acid, and 2-hydroxyphenylglycineureide-5-arsonic acid. Sol. salts are obtained by treating the products with NaOH, etc. Phenylglycylurethan-*p*-arsonic acid also is described.

**Compounds of urea and a calcium salt.** KNOLL & Co. Ger. 306,804, 1918. The compd.,  $\text{CaCl}_2 \cdot 4\text{CO}(\text{NH}_2)_2$ , white powder, stable in air and very readily sol. in  $\text{H}_2\text{O}$ , m.  $158-160^\circ$ , is obtained by evapg. an aq. soln. of the components in the required proportion to dryness or of an alc. soln. to crystn.; it is useful for subcutaneous injection in hay fever and asthma, since it does not give rise to pain as does  $\text{CaCl}_2$  alone. The compds. of  $\text{CaCl}_2$  with one, two, or three mols. of urea are hygroscopic, while those with more than four mols. have a too low content of  $\text{CaCl}_2$  for pharmaceutical purposes.

**Ethanoltrialkylarsonium hydroxides and their salts.** CHEM. WERKE GRENZACH. Ger. 305,772, 1918. Arsonium compds. of the choline type are prepd. by the action of glycol halohydrins on trialkylarsines; they possess valuable therapeutic properties. *Trimethylethanolarsonium hydrochloride*,  $\text{C}_6\text{H}_{14}\text{OAsCl}$ , very hygroscopic, prismatic crystals, m.  $218-220^\circ$ , is produced from  $\text{CH}_2\text{ClCH}_2\text{OH}$  and  $\text{Me}_3\text{As}$  at  $120-125^\circ$ ; the free base forms a viscous mass which slowly crystallizes and reacts strongly alk.  $\text{H}_2\text{S}$  does not give a ppt. with the aq. soln. of the hydrochloride; with  $\text{HgCl}_2$ , a cryst. double salt is formed. Mayer's reagent gives a faint white, KI and I a dirty brown ppt. Phosphotungstic acid gives a copious white ppt. The hydriodide forms long, hygroscopic needles; the sulfate, m.  $240^\circ$ , is hygroscopic. The diiodosalicylate, m.  $140^\circ$ , is stable in the air. The picrate, Au and Pt salts, and the picrolonate are also described. *Trimethylethanolarsonium hydrobromide* forms thick, hygroscopic prisms, m.  $219^\circ$ . *Triethylethanolarsonium hydrochloride*, consists of slender, very hygroscopic needles; the free base forms a viscous mass. The *di-iodosalicylate*, m.  $118^\circ$ , is stable in the air, as is also the *triborate*. The *picrate* m.  $152^\circ$ .

**Hydrogenated alkaloids.** C. F. BOEHRINGER & SÖHNE. Ger. 306,939, 1918. Alkaloids or their salts can be smoothly hydrogenated in aq. soln. or suspension by means of mol. H in the presence of Ni suboxide; the temp. may be normal or somewhat above (up to  $60^\circ$ ), and the pressure normal or slightly raised. Thus, hydroquinine and dihydromorphine are prepd. from quinine-HCl and morphine, resp., while cinchamylcoccaine gives hydrocinchamylcoccaine, an oily liquid which is decomposed by heat.

**Enzymes.** CHEM. WORKS (FORMERLY SANDOZ) AND A. STOLL. Brit. 120,571, Oct. 21, 1918. Peroxidases are extd. from plants rich in them (*Cochlearia armoracia*, *Cucurbita pepo*, *Brassica rapa*, etc.) by steeping thin slices in dil. acid, washing away sol. products in  $\text{H}_2\text{O}$ , then extg. the peroxidases by dil. alkali, and fractionally pptg. by alc. The products may be further purified by treating their aq. solns. with Hg salts to ppt. inactive substances. According to an example, horse-radish roots are sliced, dialyzed in running  $\text{H}_2\text{O}$ , steeped in dil. oxalic acid, washed, and extd. with  $\text{Ba}(\text{OH})_2$  soln.; the ext. is neutralized with dil. acid, and mixed with alc.; the ppt. is filtered off, the filtrate concd., and again mixed with alc.; the pptd. peroxidase is further purified by dissolving in  $\text{H}_2\text{O}$ , adding  $\text{HgCl}_2$  soln., filtering off the ppt., and pptg. the filtrate by excess of alc.; the product is finally freed from Hg by redissolving in  $\text{H}_2\text{O}$  and re-pptg. by alc. The products are suitable for intravenous injection, etc.

## 18. ACIDS, ALKALIES, SALTS AND SUNDRIES.

Our chemical industries made permanent. G. W. THOMPSON. *Chem. Met. Eng.* 20, 118-23(1919). E. H.

The French chemical industry. ANON. *Chem. Trade J.* 64, 41-2(1919). E. H.

The future of Madagascar. L. DE PRITZBUER. *Chim. & ind.* 1, 679-83(1918).  
—A review of the present, and of the probable future development of the natural resources of Madagascar. R. H. LOMBARD.

Nitric acid as a by-product of internal-combustion engines. A. W. H. GRIEPE. *Am. Gas Eng. J.* 109, 487-9, 492(1918).—The author outlines, with curves, illustrations, and calcs., the following proposed processes: "(1) An explosive mixt. of gas and air is compressed and ignited; the explosive mixt. decomposes into NO at 2250° and 40 atm. pressure. At this period H<sub>2</sub>O is injected to cool the gases quickly, thus forming NO<sub>2</sub> and HNO<sub>3</sub>. (2) In a 4-cycle gas engine, instead of letting the gases expand gradually, at the highest pressure and highest temp. (2250° and 41 atm.) H<sub>2</sub>O is injected, reducing the temp. to 1800° and the pressure to 33 atm., thus absorbing NO; the gases escape through the exhaust valve into a receiver, forming HNO<sub>3</sub>. (3) A compressor of large capacity compressing flue gases, air and a small amt. of hydrocarbon to 12 atm.; then exploding this mixt. Otherwise same operations as (1)." Cost data are given for various processes showing that the gas engine by-product process, while not the most economical, can compete with other processes in times of stress when speed is essential, and where natural gas is available. F. W. S.

Furnace settings for caustic pots. F. H. NICKLE. *Chem. Met. Eng.* 20, 65-9 (1919).—An article on the design of radial, tangential and reversible series Dutch oven type of furnace settings for countercurrent economizer NaOH pots. The development of the most efficient modern types is discussed. Illustrations and drawings accompany the text. F. W. SMITHER.

Separation of potash salts. H. P. BASSETT. *Chem. Met. Eng.* 20, 76-7(1919).—The author points out that the K salts derived from wood ashes, brines, etc., contain too much admixed salt (Na<sub>2</sub>CO<sub>3</sub>, borax, etc.) for many uses, and urges the chemists of the country to put this industry on a basis that will meet the peace-time demands. From a study of the problem of sepn. the author concludes: "(1) It is almost impossible to sep. a 3-ion system, e. g., K<sub>2</sub>SO<sub>4</sub> and Na<sub>2</sub>SO<sub>4</sub>. This is due either to the formation of double salts or the salting out of one salt by the other on account of common ion. This may be overcome in this instance by the addition of NaCl, which has 2 effects—it produces a 4-ion system and also tends to salt out the salt with a common ion, viz., Na<sub>2</sub>SO<sub>4</sub>. (2) There is that tendency in any 4-ion system to form the greatest opposites possible, e. g., in the above system KCl remains in soln. while the Na<sub>2</sub>SO<sub>4</sub> is pptd. on evapg. the soln. (3) The presence of an alkali or a salt acting as an alkali tends to throw down the heavy acid salts as they exist in soln.; e. g., in a soln. containing Na<sub>2</sub>CO<sub>3</sub>, AcONa, Na<sub>2</sub>SO<sub>4</sub> and K<sub>2</sub>SO<sub>4</sub>, the 2 latter salts will tend to be thrown down in the proportion in which they occur in soln., and this condition will be nearer and nearer approached on evapg. the soln. on account of the increase in concn. of the alkali salt. Hence, when an alkali salt is present, salts like K<sub>2</sub>SO<sub>4</sub> and Na<sub>2</sub>SO<sub>4</sub>, KCl and NaCl will have to be thrown out of soln. to free them from Na<sub>2</sub>CO<sub>3</sub> and then sepd., adhering to the 4-ion system. As to how these 3 so-called laws shall be operated depends on local conditions and original compn. of the brines to be dealt with." The author reports in detail lab. results obtained on a brine, showing that it is feasible to

produce K salts of high grade and to recover the other products in marketable form.

F. W. SMITHER.

**Potash salts in the United States of America.** ANON. *Agr. Gas. N. S. Wales* 29, Pt. 10, 716(1918).—The production of available  $K_2O$  in 1917 was 32,366 tons, which is 12% of the amt. of  $K_2O$  imported in a normal year. The amts. from inorg. and org. sources are tabulated and reported with approx. value at shipping points.

R. B. DEEMER.

**The manufacture of barium chloride.** H. TOUSSAINT. *Ind. chim.* 5, 250-2 (1918).—Early processes are reviewed. In the Kolb-Duflos 240-250 kg. of finely ground barytes (93-95%  $BaSO_4$ ) and 85-90 kg. of pulverized coal are thoroughly mixed in a hollow cylinder, and then 160-170 kg. of a 70-75%  $CaCl_2$  soln. are added. The mixt. is fused in a hand-operated furnace, where it is heated for 4 hrs. at 900-1000°. During the operation, it is important to stir the mass frequently. A good fusion is indicated by a grayish fracture with black specks of unchanged C. Lixiviation takes place in vats ( $3 \times 3 \times 1.5$  m.), provided with perforated false bottoms. Each vat is charged with 28-30 fusions coarsely broken up and contg. 50-60%  $BaCl_2$ . Hot water is added and the temp. is brought to boiling by live steam. When the soln. reaches 30-31° Bé., the operation is stopped and the liquor is removed through an outlet, while cold water is added until the d. becomes 24° Bé. After the strong liquors have been withdrawn, the sediment on the false bottom is washed with water until a minimum d. of 1° Bé. is reached. The weak liquors are used instead of fresh water to ext. future fusions. The residues should not contain more than 0.5%  $BaCl_2$ . The sol. sulfides are removed from the strong liquor, after settling, by means of  $CO_2$  and steam, S being pptd. The clear soln. is then decanted, neutralized with HCl and concd. in suitable app. to 30° Bé. Crystals of  $BaCl_2 \cdot 2H_2O$  begin to form at this point and the crystn. is allowed to continue to completion. The crystals are dried and packed into sacks or barrels. To obtain anhydrous  $BaCl_2$ , the crystg. soln. is vigorously agitated. The product is calcined. 95% pure  $BaCl_2$ , containing but little  $H_2O$  and  $CaCl_2$ , is obtained. When  $CaCl_2$  is not available, barytes is reduced at 1000-1100°, according to the reaction:  $BaSO_4 + 4C \rightarrow BaS + 4CO$ . This process is described. A product running 60-70% sol. BaS is obtained. 20-25% is sol. in acids (carbonate and silicate) and 5% is insol. BaS can be converted into  $BaCl_2$  by means of HCl. Care must be taken to remove the  $H_2S$  fumes, which can be oxidized to  $H_2SO_4$ . Wooden vats, furnished with agitators and closed by covers provided with fume vents, hoppers for the introduction of the BaS and earthenware tubes extending to the bottom of the app. for adding the acid, are used. The acid is added first, then the BaS, a little at a time. At the finish, the charge is heated by direct steam to drive out the  $H_2S$ . Tumeric paper is used to control the operation. The paper should remain slightly brown in color at the completion of the reaction. From this point on, the procedure is identical with the above. Patents have been issued on the use of Cl,  $MgCl_2$  and  $FeCl_3$  in the conversion of the sulfide.  $CO_2$  may be used to convert BaS into  $BaCO_3$  directly, but the process requires a  $CO_2$  installation. A Belgian process consists in dissolving BaS with  $Na_2CO_3$ , forming  $Na_2S$  and  $BaCO_3$ , gaining thereby, a valuable by-product.  $BaCl_2$  may be manufactured from  $BaCO_3$  directly, but the process is costly, due to the use of  $K_2CO_3$  in converting  $BaSO_4$  to  $BaCO_3$  (Fr. Pat. 408,357). ISMAR GINSBERG.

**A special bleaching powder for use in hot countries.** T. RETTIE, J. L. SMITH AND J. RITCHIE. *J. Soc. Chem. Ind.* 37, 311-317(1918).—See C. A. 13, 249.

**Nitric acid.** NORSK HYDRO ELEKTRISK KVAHLSTOFAKTIESELSKAB. Brit. 120,378, Sept. 19, 1918. The production of concd.  $\text{HNO}_3$  from N peroxide or other oxides of N is effected by passing the gas together with O and  $\text{H}_2\text{O}$  or dil.  $\text{HNO}_3$  under pressure through a series of reaction vessels, so arranged that the current of O passes in the same direction as the liquid through each individual reaction vessel, while the O and liquid pass in opposite directions through the app. as a whole. The process may be carried out at a pressure of 10 atm. and a temp. of  $70^\circ$ . App. for use in carrying the process into effect is described. Cf. C. A. 12, 2113.

**Nitric acid.** B. DAWSON. Brit. 120,869, Sept. 4, 1918. In the absorption of N oxides in an upward spray of  $\text{H}_2\text{O}$  and air in an empty tower in which the spray is produced by a jet of compressed air opening below the surface of  $\text{H}_2\text{O}$  in the bottom of the tower, the jet is surrounded by an inverted funnel having holes, the upper part of the funnel being above the level of the  $\text{H}_2\text{O}$ . This arrangement prevents irregularities in the working of the jet owing to variations in the level of the  $\text{H}_2\text{O}$ .

**Concentrating waste acids.** J. N. BROOKE. Brit. 120,951, Nov. 8, 1917. Waste acids contg.  $\text{HNO}_3$ , such as are produced in making picric acid, are concd. in earthenware, enamelled, or other acid-proof vessels provided with coils or jackets through which pressure or superheated steam is circulated. A battery of vessels, each fed from a pipe and discharging into a trough, may be used, the vapors being led to a fume pipe. Alternatively, the vessels may be arranged so that the acid flows through them in series.

**Distilling ammonia.** G. WILTON. Brit. 120,596, Oct. 11, 1917. The hot spent liquors from an  $\text{NH}_3$  still are subjected to reduced pressure in an evaporator in order to disengage the residual  $\text{NH}_3$ , and the vapors so obtained are led through a concentrating column surmounted by a reflux condenser to a coil condenser from which the  $\text{NH}_3$  is led to a receiver which is placed at a low level so as to create or assist in creating the requisite vacuum. A vacuum pump may be connected to the receiver. The evaporator is fitted with deflector plates which cause the liquor to take a sinuous course, and may be provided with heating coils. Less steam than usual may be supplied to the still with the result that a larger proportion of the  $\text{NH}_3$  is obtained in the vacuum plant.

**Ammonia; cyanogen compounds.** H. BAKER. Brit. 120,759, Nov. 16, 1917. The residual liquor left after the distn. of gas liquor with lime or the like is boiled down with  $\text{Na}_2\text{CO}_3$  or  $\text{K}_2\text{CO}_3$  to decompose certain cyanogen compds. with the production of  $\text{NH}_3$ . A compd. of a metal other than Hg is then added to ppt. the remaining cyanides and thiocyanates, or the liquor may first be used as often as desired instead of lime for the distn. of gas liquor, alkali carbonate being added as described above at each operation, the residual liquor being finally pptd. as described above. The pptd. cyanides and thiocyanates may be sepd. from the alk. liquor, which may then be used instead of lime for the distn. of gas liquor or for dissolving the metal compd. used for the pptn. of the cyanides in a subsequent operation; or the liquor, contg. the ppt., and it may be also  $\text{CaCO}_3$  derived from the lime originally used in the distn., may be evapd. to dryness. Spent oxide from gas purifiers is washed or boiled with soln. of alkali carbonate and the soln. obtained is concd. to decompose certain cyanogen compds. and then pptd. as above described. The pptd. cyanides and thiocyanates or the mixt. obtained in the evapn. to dryness above described, or the cyanogen compds. obtained according to 110,819 and 112,329 are heated with or without the addition of alkali carbonate and in the presence or absence of air to obtain  $\text{NH}_3$ . In the presence of air, an oxide is obtained which may be used again, and as the  $\text{NH}_3$  is first liberated and subsequently  $\text{SO}_3$ , it is possible to collect them sep. In the absence of air, a sulfide is obtained which may be roasted to obtain a soln. which, after neutralization, may be used for the pptn. of the cyanides as above described.

**Nitrates by bacterial action.** C. T. THORSSELL and H. L. R. LUNDEN. U. S. 1,288,754, Dec. 24. Nitrate-forming bacteria are allowed to act upon 1  $m^3$  of nutrient soln. containing 150 kg.  $\text{Ca}(\text{NO}_3)_2$  and 8 kg.  $(\text{NH}_4)_2\text{SO}_4$  until the soln. is completely oxidized and contains 160 g.  $\text{Ca}(\text{NO}_3)_2$  per l. 60 l. of this soln. are sepd. and to the remainder there are added  $\text{H}_2\text{O}$  60 l.  $(\text{NH}_4)_2\text{SO}_4$  8 kg. and a combining proportion of  $\text{CaCO}_3$  for the continuation of the process. In another and preferred manner of carrying out the oxidation, 1  $m^3$  of soln. is formed containing  $\text{Ca}(\text{NO}_3)_2$  150 kg. and  $\text{NH}_4\text{NO}_3$  10 kg. At complete oxidation, a soln. is obtained which contains 170 g.  $\text{Ca}(\text{NO}_3)_2$  per l. 120 l. of this soln. are sepd. and transformed into  $\text{NH}_4\text{NO}_3$ , a portion of which is added to the residual 880 l. of soln. from the first oxidation for continuation of the process.

**Nitrates by bacterial action.** C. T. THORSSELL and H. L. R. LUNDEN. U. S. 1,288,755, Dec. 24. In the oxidation of  $\text{NH}_3$  or  $\text{NH}_4$  compds. to nitrates by the action of bacteria in mellow soil or other nutrient, the deleterious action of molds or other enemies of nitrifying bacteria is prevented by the addition of small amts. of  $\text{PhOH}$ ,  $\text{CuCN}$ ,  $\text{NaCN}$ ,  $\text{NaF}$ , aniline or other poisons which are harmless to the nitrifying bacteria.

**Nitrates by bacterial action.** C. T. THORSSELL and H. L. R. LUNDEN. U. S. 1,288,756, Dec. 24. A porous solid substratum material such as peat or sponge carrying nitrifying bacteria is mixed with  $\text{CaCO}_3$  and perforated trays containing this material are placed one above another. A soln. of  $\text{NH}_4$  salts to be oxidized is allowed to percolate through the material in the trays while exposed to free access of air.

**Potassium chloride from brines.** J. W. HORNSEY. U. S. 1,288,592, Dec. 24,  $\text{KCl}$  is sepd. from a soln. containing also  $\text{NaCl}$ , borax,  $\text{Na}_2\text{SO}_4$  and  $\text{Na}_2\text{CO}_3$  by treating the soln. with  $\text{CO}_2$  to remove the carbonate, filtering off the soln. and evapg. the filtrate to remove  $\text{NaCl}$ , cooling and dilg. the soln. and pptg.  $\text{KCl}$  and borax, and then by successive evapns. and coolings removing  $\text{NaCl}$  and  $\text{Na}_2\text{SO}_4$  as a result of the evapns. and removing borax and  $\text{KCl}$  as a result of the coolings, sepg. the borax and  $\text{KCl}$  by dissolving to form a soln. having a sp. gr. of 1.12–1.22 at a temp. of  $95^\circ$ , cooling to ppt. borax from the soln. and then, after sepn. of the borax, concg. and cooling to ppt.  $\text{KCl}$ . U. S. 1,288,593 specifies a similar method, in which the filtrate obtained after sepn. of  $\text{KCl}$  may be returned to the cycle for more complete recovery of the borax and  $\text{KCl}$ .

**Separating borax and potassium chloride from solutions.** J. W. HORNSEY. U. S. 1,288,591, Dec. 24. Solns. containing both borax and  $\text{KCl}$  are dild. to a sp. gr. of 1.12–1.22 at a temp. of about  $95^\circ$ , cooled to about  $5^\circ$  to ppt. borax, and, after sepg. the borax from the soln., the latter is concd. at a temp. of about  $95^\circ$  and then again cooled to ppt.  $\text{KCl}$ .

**Calcium hypochlorite.** A. HOFFMANN and A. H. KROFF. U. S. 1,288,587, Dec. 24. The object of the invention is to prep. a uniform compn. suitable for purifying  $\text{H}_2\text{O}$  and containing a standardized % of  $\text{Cl}$  and insol. matter. Three sep. portions of com.  $\text{Ca}(\text{OCl})_2$  each of equal wt. are used in making up the product. One portion is given no special treatment, a second portion is heated to about  $50^\circ$  in a closed chamber for 4–5 weeks partially to convert it into  $\text{CaCl}_2$ , and the third portion is allowed to stand in contact with the air for 1–2 weeks. By mixing these three portions together a material is obtained containing  $\text{Ca}(\text{OCl})_2$  65%,  $\text{CaCO}_3$  5% and  $\text{CaCl}_2$  30%, which is neither dusty nor sticky.

**Titanium hydrates.** M. FLADMARK. U. S. 1,288,863, Dec. 24. Hydrates, hydrated oxides or hydrated salts of  $\text{Ti}$  are pptd. from concd. solns. of  $\text{Ti}$  compds., e. g., a soln. containing 80–350 g.  $\text{TiO}_2$  per l. and 82–410 g.  $\text{SO}_3$  per l. not bound to bases other than  $\text{Ti}$  (such as the solns. obtained by decomposing ilmenite with  $\text{H}_2\text{SO}_4$  in

the manner described in Norwegian pat. to Jebsen, No. 27,292), by heating the solns. in a Pb-lined vessel. The heating may be carried out at the b. p. of the soln. or the reaction and pptn. may be hastened by heating in an autoclave under pressure. A ppt. may be obtained carrying 15-25% combined  $H_2O$ , 3-7%  $SO_3$ , a small amt. of Fe oxide and the remainder  $TiO_2$ .

**Sodium sulfide.** E. M. SYMMES. U. S. 1,289,016, Dec. 24.  $Na_2S$  is produced by fusion of  $Na_2SO_4$  with C in a container of corrosion.

**Ammonium sulfate.** S. E. LINDER. Brit. 121,082, June 3, 1918. Neutral  $(NH_4)_2SO_4$  is produced by adding to the slightly acid sulfate a small proportion of  $(NH_4)_2CO_3$  in the solid state or in soln. in sufficient  $H_2O$  merely to moisten the sulfate, or partly in the solid state and partly in soln. in sufficient  $H_2O$  merely to moisten the sulfate.

**Lead arsenate.** J. LYTLE. Brit. 121,101, Aug. 19, 1918. Pb arsenate is produced by thoroughly mixing, preferably by rubbing or grinding,  $PbCO_3$  or white Pb with  $H_3AsO_4$  in the presence of  $H_2O$ . A concd. soln. of  $H_3AsO_4$  may be used, and  $H_2O$  may be added at the end of the reaction, to produce a paste of the desired consistency.

**Alumina; ammonium sulfate.** J. P. LARSON and W. D. BERGMAN. Brit. 120,550, Aug. 26, 1918. Clay, bauxite, or other natural substance containing Al together with Fe and  $SiO_2$  is treated with  $H_2SO_4$  to yield an impure soln. of  $Al_2(SO_4)_3$ . The soln. is treated with a reducing agent such as  $SO_2$  or a sulfite to reduce ferric to ferrous sulfate, and is mixed while at 70-100° with  $(NH_4)_2SO_4$ , allowed to settle at this temp., and the decanted soln. cooled to sep. crystals of  $NH_4$  alum. The crystals are decomposed by exposing them to  $NH_3$ , either gaseous or in soln., to yield  $(NH_4)_2SO_4$  and  $Al(OH)_3$ , which may be heated to obtain  $Al_2O_3$ .

**Alumina.** E. E. and P. C. DUTT. Brit. 120,638, Mar. 4, 1918. A mixt. of calcined clay or bauxite, or both, with Ca or other alk.-earth chloride is heated to bright redness in a stream of  $As_2O_3$  vapor, producing  $AsCl_3$  which is decompd. by steam into  $As_2O_3$  and HCl, and an aluminate. The residue is dissolved in HCl and treated with Ca aluminate to ppt.  $Al_2O_3$  and to re-form  $CaCl_2$ , which, after the addition of some lime to ppt. the Fe, may be used again.

**Thorium compounds.** J. V. CLARKE and W. A. CLARKE. Brit. 120,748, Sept. 21, 1917. Solns. contg. Th, obtained, *e. g.*, by dissolving in  $H_2O$  the product of the action of  $H_2SO_4$  on monazite sand, are treated with oxidizing agents such as  $KMnO_4$ , or  $NaMnO_4$ , or  $H_2O_2$  in the presence of acid. Hydrated Th oxide or peroxide is pptd. and may be dissolved directly in  $HNO_3$  or other acid, and the resulting soln. may be crystd. The Th nitrate may be purified by pptn. by the oxidizing agent first employed, or the soln. may be treated with  $Na_2CO_3$  in excess, which dissolves the Th carbonate first produced. The soln. is filtered and treated with NaOH to ppt. Th hydroxide, which is then dissolved in  $HNO_3$ .

**Preparing decolorizing carbon.** R. HAYASHI and KWANTO SANJO KABUSIKI KAISHA. Brit. 121,035, Feb. 11, 1918. Decolorizing C is made by soaking sawdust, chaff, etc., in a soln. of  $CaH_4(PO_4)_2$ , or by sprinkling the material thus soaked with  $NH_4OH$ , carbonizing the same, extg. the Ca phosphate with  $H_3PO_4$ , and washing. During the final washing, a part of the  $H_3PO_4$  may be allowed to remain and the C then used for filtering crude sugar sirup, while the filtered sirup may be added to beverages to impart the flavor of  $H_3PO_4$ .

**Albumins.** S. SAROW. Brit. 121,141, June 28, 1917. Albumins are extd. in a pure and undenatured condition from soy bean and other vegetable materials by crushing the raw material, removing oil therefrom by a solvent, then removing the solvent

by a vacuum or by air at a low temp., then extg. the albumins by means of  $H_2O$ , alkali or salt soln., or other non-alc. liquid which will not denature the albumins, removing colloidal, etc., impurities from the ext. until a transparent clear soln. is obtained, and finally pptg. the albumins from the clear soln. The removal of impurities from the ext. may be effected by first passing the ext. through a centrifugal separator and then filtering and fractionally pptg. the liquid by adding a little  $H_2SO_4$  or  $H_2SO_3$ , allowing to stand, decanting, and filtering; another method consists in carefully pptg. the albumins together with impurities by an acid ( $H_2SO_4$  or  $HOAc$ ), decanting, redissolving the albumins in dil.  $H_2SO_3$  or  $HCl$ , and filtering. The wet albumins may be finally dried *in vacuo*, and are suitable for use in the manuf. of plastic materials, etc.

Obtaining products by destructive distillation. E. L. RINMAN. Brit. 120,724, Oct. 30, 1918. Various products ( $NH_3$ ,  $CH_3OH$ , acetone, paraffins, lubricating oils, wax, etc.) are obtained by the dry distn. of mixts. of organic acids with strong bases. The process is particularly applicable to waste lyes from soda-cellulose manuf., waste lyes obtained by dissolving vegetable substances in boiling  $NaOH$  soln.,  $Na$  salts of resin acids and fatty acids obtained, *e. g.*, by treating wood with  $NaOH$ , liquors obtained by boiling waste sulfite-cellulose lyes with  $Ca(OH)_2$ , and waste liquors obtained in the treatment of vegetable textile fibers with alkalies. The distn. is carried out in stages, each stage corresponding with the production of a specific product or products, which are thus collected separately. The heating is preferably effected by the introduction of superheated steam, or superheated steam mixed with the distn. gases. Examples are given of the treatment of waste liquor obtained in the treatment of straw with  $NaOH$  lye, waste soda-cellulose liquor, waste liquor obtained by dissolving wood in  $NaOH$  lye, resin acids and fatty acids, waste liquors from retting flax with  $NaOH$  or the treatment of esparto with  $NaOH$ , and the liquor obtained by boiling waste sulfite-cellulose lye with  $Ca(OH)_2$ .

Catalytic apparatus; hydrogen; ammonia; nitric acid; heat-exchangers; distilling. GEN. CHEM. CO. Brit. 120,546, Feb. 28, 1918. A mixt. of three vols. of  $H$  with one vol. of  $N$  for the synthesis of  $NH_3$  is produced by blowing a producer alternately with air and with air and steam in regulated proportions and then adding steam and passing the gases over a catalyst to convert the  $CO$  into  $CO_2$  and  $H$ , the  $CO_2$  being then sepd. The  $N-H$  mixt. after purification is passed through a catalytic app. for the production of  $NH_3$ , which is then oxidized to produce  $N$  oxides in another catalytic app. Dil.  $HNO_3$  is produced from the gases and this is then concd. by means of air and  $H_2SO_4$  in a distg. app. A suitable construction, with operation, is specified.

Catalytic agents. G. FRABETTI. Brit. 120,551, Sept. 3, 1918. Platinized asbestos, for use as a catalyst, is prepd. by dissolving  $Pt$  in aqua regia, evapg. the soln. to dryness, extg. the residue with  $HCl$ , neutralizing the soln. with  $Na_2CO_3$ , mixing it with a paste of asbestos and distd.  $H_2O$ , and reducing at  $60^\circ$  by  $HCOOH$ ; the product is finally washed, dried, carded, and made into flakes.

Fireproofing compositions. S. A. WALTON. Brit. 120,421, Nov. 6, 1917. In fireproofing wood, cloth, paper, metals, etc., coating or impregnating the object to be fireproofed with a compd. containing a pptd. double borate of  $Zn$  and  $Al$  and a colloidal medium. The double borate of  $Zn$  and  $Al$  is formed by dissolving mol. proportions of  $ZnSO_4$  and  $Al_2(SO_4)_3$  in hot  $H_2O$  and adding to the boiling soln. the requisite quantity of borax to ppt. the double borate. The fireproofing compn. is formed by suspending the ppt. in a colloidal medium, preferably one formed by dissolving 4 oz. gelatin in a gal. of  $H_2O$  at  $90^\circ$  and adding 12 oz. of  $NH_4Cl$ , the temp. being maintained until effervescence ceases. When subjected to great heat, the compd. forms an amorphous glaze which offers great resistance to high temp. or flame.

**Refractory compositions.** G. MARSH. Brit. 120,471, Dec. 3, 1917. Ground furnace slag, slate waste, infusorial earths, and similar materials in admixt. with portland, Roman, or hydraulic cement, and, if desired, plumbago, are mixed with a soln. of a protein substance such as casein, blood, glue, or gelatin. The soln. may contain also Na or K silicate, with or without addition of borax, boric acid, or  $\text{NH}_3$ . The mixt., when dried, is intended for use as a refractory material. Slate dust, slate waste, marble, granite, or similar material, mixed with portland, Roman, or hydraulic cement is mixed also with a similar soln. to form artificial slate.

**Containers for fluids.** G. H. HADFIELD and A. E. BAWTREE. Brit. 120,934, Nov. 26, 1917. Tubes of cardboard or other porous material, to be used for making containers for fluid, are rendered impervious by coating the interior surface with a colloid such as gelatin, which is hardened by an agent applied previously. The hardening agent may be incorporated in the material of the tube during its manuf.

**Ink ribbons.** B. L. BEALL. Brit. 121,114, June 27, 1918. Ink ribbons are woven from pure undyed silk and, before being impregnated with ink, are treated with a soln. of  $\text{SnCl}_4$  or other salt of Sn.

## 19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLEININGER.

**The nature of the air content of pugged clays.** H. SPURRIER. *J. Am. Ceram. Soc.* 1, 584-5(1918).—A sample of the occluded gas from pugged clay showed:  $\text{CO}_2$  3.85,  $\text{O}_2$  13.46,  $\text{CO}$  1.92,  $\text{N}_2$  80.77%. C. H. KERR.

**Sudanese pottery.** F. STIRK. *Trans. Eng. Ceram. Soc.* 17, 226-35(1918).—River Nile mud is used. Wares are built up by hand and fired by placing in pits and covering with fuel. C. H. KERR.

**Note on a firebrick from the crown of an electric steel-melting furnace.** W. J. REES. *Trans. Eng. Ceram. Soc.* 17, 248-9(1918).—Samples from a fire brick crown of a half-ton Greaves-Etchells furnace which had lasted 145 charges showed the following analysis:  $\text{SiO}_2$ , 51.83;  $\text{Al}_2\text{O}_3$ , 38.73;  $\text{TiO}_2$ , 6.68;  $\text{Fe}_2\text{O}_3$ , 1.56;  $\text{CaO}$ , 0.31;  $\text{MgO}$ , 0.19;  $\text{K}_2\text{O}$ , 0.59;  $\text{Na}_2\text{O}$ , 0.32%. Softening point was cone 37. The fluxed end of the brick showed abundant development of sillimanite. These bricks were made from a newly discovered bauxite clay containing numerous spherulites of bauxite. It is almost non-plastic and requires a plastic clay bond. Samples have analyzed up to 50%  $\text{Al}_2\text{O}_3$  and up to 10%  $\text{TiO}_2$  and softening points have run from cones 32 to 38. C. H. KERR.

**Corrosive action of flue dust on fire bricks.** J. W. MELLOR. *Gas J.* 144, 421-3 (1918).—A report of the Refractory Materials Committee to the Institution of Gas Engineers (England). Trials were made in a small furnace 18" high, 18" wide by 9" deep, heated by air blast with air at 3-4 lbs. and town gas at 3-4 in. pressure, both preheated to 350-400° by an auxiliary burner. A tube running down the center of the burner carries the dust under test. It is sucked into the burner blast and projected downward on to the test brick. Uniform furnace conditions were maintained for 1/2 hr. both before and after the period of feeding in dust. The following dusts were tried: (1) boiler flue dust of a slate-brown color, (2) boiler flue dust of a brown color, (3) deep red dust from the top of the retort-bench of a gas-works, (4) dust from the slag-chamber between a steel-smelting furnace and the regenerator, (5) dust from a blast-furnace Cowper stove, (6) bull dog, (7) red hematite ore, (8) top cinder, (9) lime from calcined marble, (10) equal amts. of  $\text{CaO}$  and  $\text{NaCl}$ , (11) salt, (12)  $\text{Na}_2\text{SO}_4$ , (13) equal amts. of salt and potash spar, (14) equal amts. of Na and Ca silicates. Analyses of the flue dusts follow:

| Soda-lime glass.....                           | s.P.; s.C. | s.P.; m.C.    | .....                      |

In the table, P = penetration; C = corrosion; s = slight; d = deep; k = complete; m = medium; gC = great corrosion or slagging. In  $\text{SiO}_2$  the bond is the most vulnerable part.  $\text{Fe}_2\text{O}_3$  corrodes fireclay more easily than it does  $\text{SiO}_2$  bricks.  $\text{SiO}_2$

conversions are hastened by the dusts, due possibly to the alk. vapors in the dust. If the dust forms a surface glaze the brick is largely protected from further attack. Further reports will be made by the Committee.

C. H. KERR.

Our knowledge of the refractory products industry. J. BURN. *Chim. & ind.* 1, 579-600(1918).—A review of the progress, during the war, of the French refractory products industry. *Dolomitic bricks*: The disintegration of dolomitic furnace bricks before use, as a result of slaking, may be greatly reduced by mixing 5-6% of kaolin with the dolomitic carbonate before burning it. In making the bricks, the calcined dolomite is mixed with boiled tar, and pressed under 400-500 kg./cm<sup>2</sup>. pressure. They are stable for only 2-3 days and should be used at once. However, they are as stable with respect to slaking as bricks made from "dead burned" magnesium carbonate, and may replace them in localities where dolomite is more abundant than MgCO<sub>3</sub>. *Magnesia*. Before the war France was largely dependent on Styrian magnesia for furnace blocks, but during the war MgCO<sub>3</sub> from Greece (Euboea) and Italy (Caglian-cello) was calcined in France. Grecian magnesia contains less Fe<sub>2</sub>O<sub>3</sub> than Styrian magnesia, and requires a correspondingly higher temp. for burning. Also, bricks made from it slake rather easily and exhibit considerable shrinkage when submitted to prolonged high temp. The Italian MgCO<sub>3</sub> deposits contain siliceous and calcareous concretions, the removal of which increases the cost of prepg. it. MgO bricks are molded under a pressure of 500 kg./cm<sup>2</sup>. with no binder except H<sub>2</sub>O, and then burned at 1550°. *Silica-alumina products*: The behavior of kaolinite (argil) blocks when subjected to pressure at high temp., was studied. The resistance to pressure is increased by replacing some of the clay by pure silica sand, and molding dry (8-10% H<sub>2</sub>O) under a pressure of 200-400 kg./cm<sup>2</sup>. Also, the addition of 10% of fat coal helps. Blocks composed of 1 part sand and 1 part kaolin withstood 10 kg./cm<sup>2</sup>. at 1200°, and 4 kg. at 1460°. *Silica bricks*: The manuf. of silica bricks is described; and the relation between their stability and the transformation of quartz into tridymite and cristobalite is discussed. A silica brick should contain at least 95% SiO<sub>2</sub>; should have a crushing resistance of 150 kg./cm<sup>2</sup>. cold, and at least 20 kg. at 1600°; and should exhibit only slight swelling, which quality is probably assured by its having a density of 2.38 to 2.42.

R. H. LOMBARD.

Electric furnace treatment of refractories. R. S. HUTTON. *Trans. Eng. Ceram. Soc.* 17, 236-43(1918).—An open-hearth steel furnace reaches 1650° and few refractories are burned to or even capable of withstanding that temp. Should not first grade refractories be fired to 2000°? This requires elec.-furnace firing. In the elec. furnace materials may be fully shrunk owing to the high temps.

C. H. KERR.

Heat balance on a producer-gas fired chamber kiln. R. K. HURSH. *J. Am. Ceram. Soc.* 1, 567-77(1918).—Tests were made at the Baker Clay Co., Grand Ledge, Mich., of a 16-chamber kiln and three 6-ft. water-seal pressure producers. *Results*: Total heat input from coal, air, steam and carbon in clay, 100%; heat to raise temp. of clay and drive off water, 43.59%; loss due to sensible heat of flue-gas, 32.35%; loss due to conduction, radiation, etc., from kiln, 8.72%; loss due to conduction, radiation, etc., from producers, 14.72%; loss due to unburned carbon in ashes, 0.62%.

C. H. KERR.

Hydraulic separation as applied to the recovery of fine coals, shales and clays (DRAPER) 1. Refractory materials in gas-works, from a user's point of view (LEATHER) 21.

DUNNICLIFF, H.-B.: *Laboratory Glassware Economy*. London: Macmillan & Co., Ltd.; Saint Martin's St. 92 pp. 4s. For review see *Rev. sci.* 56, 543(1918).

**Refractory material for furnace construction.** L. P. KRAUS, JR. U. S. 1,289,049, Dec. 24. Bauxite or similar material is powdered, mixed with twice its volume of ground wood and molded into blocks with  $H_2O$  and glucose or other binder. The blocks are dried and then roasted at a temp. (preferably about  $160^\circ$  below the m. p.) sufficiently high to produce clinkered material in the form of spongy grains with the cleavage planes destroyed. Air is supplied during the heating to oxidize and remove impurities, and after clinkering the material is crushed to the degree of fineness desired for use. Most of the  $Fe_2O_3$  in the bauxite is eliminated during the process.

**Washing clay.** W. FELDENHEIMER. Brit. 121,191, Dec. 6, 1917. In a process for cleaning clay by treating an aq. suspension first in one vessel with a deflocculator such as weak  $Na_2CO_3$  to enable impurities to settle out and then in another vessel with a flocculator, such as alum soln. which causes the clay to settle, as described in 106,890 (C. A. 11,2607), the flocculating reagent is added so slowly, or in such total quantity relatively to the quantity of the deflocculator, as to cause flocculation or coagulation of the clay, but not rapid sedimentation. By this means, there is obtained a sepn. from the clay in suspension of impurities not ordinarily sepd. therefrom by the deflocculator alone. With certain deflocculators, such as a weak soln. of  $Na_2CO_3$ , a strong soln. of the same material may be used as a flocculator. When  $Na_2CO_3$  is employed, discoloration of the clay may be prevented by the addition of ultramarine prior to the addition of the flocculating agent. Various flocculating and deflocculating agents are described.

## 20. CEMENT AND OTHER BUILDING MATERIALS.

C. N. WILEY.

Some mix-crystals of calcium ferrite and aluminate. E. D. CAMPBELL. *J. Ind. Eng. Chem.* 11, 116-20(1919).—Continuing his researches on the equil. relations of the oxides composing portland cement clinker, C. has applied his methods of slow cooling to produce large crystals (C. A. 9, 703) and absorption of the liquid phase at a definite temp. (C. A. 7, 3400) to several  $CaO.Fe_2O_3.Al_2O_3$  melts. From pure  $Al_2O_3$ - $Fe_2O_3$  melts only the compds.  $CaO.Fe_2O_3$  and  $2CaO.Fe_2O_3$  could be isolated confirming the work of Sosman and Merwin (C. A. 10, 2673). From a melt of compn.  $8CaO$ -. $3Al_2O_3$  crystals of the compd.  $3CaO.Al_2O_3$  were isolated, though these could not be prepd. from melts of compn.  $4CaO.Al_2O_3$  due to crystn. of  $CaO$  (C. A. 11, 2953). From melts of compn.  $8CaO$ -. $3R_2O_3$  containing 2  $Fe_2O_3$  to 6  $Al_2O_3$  solid solns. containing 1  $Fe_2O_3$  to 7  $Al_2O_3$  were isolated when liquid phase contained less than 3  $Fe_2O_3$  to 5  $Al_2O_3$ . With liquid phase between  $3Fe_2O_3$ -. $5Al_2O_3$  and  $Fe_2O_3$ -. $Al_2O_3$  solid solns. containing 3  $Fe_2O_3$  to 5  $Al_2O_3$  were isolated. All samples were hydraulic. Substitution of  $Fe_2O_3$  for  $Al_2O_3$  decreased the amount of  $CaO$  which could be held in combination. J. S. LAIRD.

**The elasticity of pure cement.** L. JOUAN. *Compt. rend.* 167, 591-3(1918).—The coeff. of elasticity of a small prism of neat cement was detd. in the following manner: One end of the test piece, 38.6 cm. in length, 2.96 cm. wide, 1.43 cm. thick, wt. 286.07 g., d. 1.75, was fastened solidly in a wall; the other end on which the force was applied was gripped in a jaw suspended by its upper hook at the end of a balance beam. A mirror fastened near the knife edge of the beam served to det. the deformation of the test piece by the method of Poggenдорff. By an arrangement of funnels to discharge certain wts. of sand the test piece was subjected to forces alternatively in both directions reaching progressively 500 g. From the formula  $E_f = 4Pl/a^3bf$ , where  $P$  = force in kg.,  $f$  = corresponding deformation in cm.,  $l$  = the distance between points of fixation in the wall and jaw,  $a$  = thickness of the test piece,  $b$  = width,  $E_f = 1.080 \times 10^8$

kg. per sq. cm. With another procedure carried by moving the test piece from its position of equil. and registering the vibrations on a smoked cylinder, 45.5 vibrations per second were obtained. In applying the formula  $E_u = 48\delta\pi^2 N^2 l^4 / (a^3 \times 1.87^4 \times 9.81 \times 10^8)$  in which  $E_u$  is the coeff. of elasticity in kg. per cm.;  $\delta$  the density,  $N$  the number of vibrations per sec.;  $l$  the distance from the fixed end to the movable end of the test piece,  $E_u = 1.074 \times 10^5$  kg. per sq. cm. Further detns. by both methods gave results agreeing very closely with these figures. The expts. show that a given test piece at a given time has a well defined coeff. of elasticity.

H. A. BRIGHT.

**Influence of gypsum on the blast furnace slag used in the manufacture of cement.** E. BERESLAVSKY. *Chem. Met. Eng.* 20, 25-8 (1919).—Puzzolan cement manuf. from slag and quick-lime at the Alexandrook South Russian works of the Briansk Co. gave 35 kg. per sq. cm. at 7 days, 45 kg. at 28 days for neat briquets, and 12 kg. for 7 days, 16 kg. for 28 days for 1 to 3 sand briquets. Pats made of this cement showed constancy of vol. A study was made of this slag in combination with lime and gypsum using both granulated and degranulated slag (slag in which all granulation properties had been eliminated by preliminary heating at a high temp. and subsequent cooling in a closed kiln). A slag cement made of granulated slag and 10% of quick-lime which had a good stress lost its stress upon the addition of 5% of gypsum. Sand briquets made from both granulated and degranulated slags with 4 to 6% of gypsum when placed in water disintegrated and showed deleterious vol. changes. Increasing the amt. of gypsum to 10% gave 10.4 kg. per sq. cm. at 7 days and 23 kg. at 28 days. Additions to 15% of  $\text{CaSO}_4$  gave about the same resistances. After further additions the briquets showed rapid lowering in strength tests. Cements of this type—low lime to gypsum—provided strength requirements are sufficient are perhaps more resistant to sea water and  $\text{H}_2\text{SO}_4$  and if properly prepared should be favorably considered for some classes of marine construction and where resistance to  $\text{SO}_3$  ions is a factor.

C. G. F.

**Storage tanks made of reinforced concrete.** F. W. FRERICHs. *Trans. Am. Inst. Chem. Engineers* 1919, Preprint.—These tanks were of exceptional size and were made of concrete because of steel-plate shortage during the war. Before their erection permeability tests were made both with water and ammonia liquor in four small exptl. tanks which were subjected to systematic tests. The concrete mixt. was 1 part cement, 2 parts sand and 4 parts gravel. To one of them 2% of hydrate of lime was added and to 2 others 2% of com. waterproofing material (stearates). The iron cover was luted on to prevent evapn., as the tests were operated in St. Louis in the summer time. The inside area per exptl. tank was 15.7 sq. ft. and outside area 35.74 sq. ft. After 10 days' drying the tanks were filled with water with the result that the av. evapn. (omitting the first day for satn.) per day per sq. ft. outside area (of 25 sq. ft. atm. exposure) was 2.8 cu. in. for the straight concrete mixt. 1.0 cu. in. for the hydrated lime mixt. and 0.7 and 2.8 cu. in. for the com. stearate mixts. The aqua ammonia tests showed no perceptible decrease in strength during the ten days' exposure to the hot sun. Omitting the first 2 days for satn. of the concrete, the av. evapn. per day per sq. ft. outside area, 25 sq. ft., exposed to the atm., was 3.5 cu. in. for the straight concrete mixt., 1.0 cu. in. for the hydrated lime mixt. and 1.25 cu. in. and 1.02 cu. in. for the stearate mixts. The dried test tanks were then given 3 coats of raw gas tar, the first one thinned down with turpentine (causing penetration of  $1/8$  in.). After drying for a week test with ammoniacal liquor during several months showed no appreciable loss in contents. With this as a basis 3 tanks were built in a concrete pit beside the Mississippi River using Red Wing Portland Cement 1 part, 2 parts sand and 4 parts

washed and screened Meramec gravel. Tanks were 35 ft. inside diam., 26 ft. deep. Walls were 7 in. thick. Roof was 6-in. concrete. Inverted steel man-hole covers were used, which were luted into water, and the whole of the top was water-sealed to prevent gas escaping through the concrete by an annular curb construction. The sides were heeled into circular chases in the floor of the pit. The mortar was of a stiff consistency, thoroughly rammed continuously day and night during erection with continuous upward movement of the form during erection. The forms carried a platform for delivery of material and workmen. The whole was properly stayed and reinforced by steel. The rate of form movement varied from 8 in. per hr. during the cool hrs. to 14 in. per hr. during the heat of the day. Three coats of tar were applied after the tanks were dried. Water test developed slight leakage through lifting-cracks due to slow movement of the forms. These lifting cracks were avoided in the other tanks by more rapid movement. Capacity of each tank was 185,000 gals. and cost approx. \$10,000 exclusive of the tank pit. Also in *Chem. Met. Eng.* 20, 234-6(1919).

JAMES R. WITHROW.

**Water content and concrete strength.** *Eng. Mining J.* 106, 998(1918).—A brief résumé of expts. made at Lewis Inst., Chicago, by D. A. Abrams, to study the effect of various quantities of water on the strength of concrete. A curve is given showing the results of compression tests on 6 × 12 in. cylinders with mixes ranging from 1 part of cement and 9 of aggregate to 1 cement and 2 parts aggregate by vol. A composite curve can be drawn as the effect of proportional changes in the mixing is approx. the same for all mixes of concrete. With the consistency most used in concrete construction which contains about 110 to 115% of water (where 100% is the amt. of water giving max. strength) a concrete is obtained which gives 85 to 90% of the max. strength that can be secured from a given amt. of cement and the same aggregates. As the amt. of water is increased there is a rapid falling in strength. With an amt. of water double that required for max. strength, the concrete has only 20% max. strength. In the "sloppy" concrete often used (135% of water) one-half the strength is lost. Any method that involves puddling, tamping, rolling or vibrating, or the exertion of pressure in any manner, will have a tendency to increase the strength of the concrete regardless of the amt. of water used.

**An advance towards greater economy of fuel and increased output in the dead-burning of magnesite and dolomite and the burning of cement.** E. STEIGER. *Trans. Eng. Ceram. Soc.* 17, 250-9(1918).—The old shaft kilns are practically obsolete. The rotary kilns are standard in cement burning and have received practically all the attention recently. The patented Steiger kiln is a producer-fired shaft kiln with automatic charging and discharging devices and with "perfect heating of the air of combustion." The "rotator" at the bottom accomplishes discharging. The capacity of the kiln is about 14 tons per day, the fuel consumption under 20% of the wt. of burned material (compared with 35-40% in the old kilns) and the power consumption 30 h. p.

C. H. KERR.

**Some factors influencing the time of set of calcined gypsum.** F. F. HOUSEHOLDER. *J. Am. Ceram. Soc.* 1, 578-84(1918).—Increasing % H<sub>2</sub>O decreased viscosity and increased time of set. Vigorous stirring when mixing with H<sub>2</sub>O decreased the time of set. Variation in temp. of the mixing H<sub>2</sub>O had no effect on time of set. C. H. K.

**Volume-temperature correction for creosote oil measurements.** S. R. CHURCH AND JOHN MORRIS WEISS. The Barrett Co. *Proc. Am. Wood Preservers' Assoc.* 1918, 160-6.—The mean coeff. of cubical expansion of coal-tar creosote oil in the liquid phase below 79° should be taken as 0.0007 instead of 0.0008 per ° C. A large and inconst. vol. change takes place when naphthalene is crystallizing or dissolving, so no

accurate correction factor can be established below the temp. where the oil is entirely liquid. The customary practice of basing the purchase and use of creosote on a temp. of 100° F. is commended.

GEO. M. HUNT.

**Tentative specifications for wooden paving blocks for exposed pavements.** H. VON SCHRENK, *et al.* *Proc. Am. Soc. Testing Materials* 18, Pt. I, 625-9, 340-6(1918).—The tentative specifications covering wood used, treatment, preservatives and inspection, are practically the same as adopted by Am. Wood Preservers' Assoc., Jan., 1917 (cf. *C. A.* 11, 695). The only changes in preservatives are increase in max. sp. gr. permitted for coal-tar oil to 1.14 and decrease of min. sp. gr. of fraction 315-55° to 1.09 for both coal-tar oil and distillate oil. A specification for water gas tar is presented as information.

**Waterproofing concrete.** A. E. HORN. *Brit.* 120,918, Nov. 19, 1918. A soln. contg.  $\text{NH}_4$  compds. of resinic or resinous acids, with or without  $\text{NH}_4$  compds. of fatty acids, is added to the  $\text{H}_2\text{O}$  mixed with portland cement in making concrete. The resinate may be formed from ordinary resin or colophony or from harder resins including the resin acids of Manila and other copals. Fatty acids which can be used are stearic and oleic or stearic acid mixed with palmitic acid. The stearic acid should be free from lubricating hydrocarbons. Other volatile alkalies such as some of the amines may be used in whole or part substitution for  $\text{NH}_4$ . Preferably resin acid and stearic acid are mixed in mol. proportions. The  $\text{NH}_4$  may be added in quantity to sat. the acids exactly or to leave an excess of  $\text{NH}_4$ , but preferably less  $\text{NH}_4$  is used than is required to combine with the resinic and fatty acids so as to leave some uncombined resin. The proportion of resinate or of mixed resinate and stearate, reckoned as anhydrous, which is added to the cement is from half to two %. The soln. is stated to increase the proportion of colloidal silicates in the cement.

**Road-making composition.** G. ROSS. *Brit.* 120,961, Nov. 26, 1917. A material for surfacing roads is made by mixing preferably 100 parts of earthy material, such as loam, soil, or clay, with 35 parts of  $\text{H}_2\text{O}$  to form a thin mud, and adding in succession 20 parts of asphalt, natural bitumen, or coal-tar pitch, or other artificially prepd. pitch, and 1 part of a solvent for the asphalt, etc., such as dead oil, cresol, or crude carbolic acid. The bitumen may be added in a powdered state, or it may be liquefied by heat. In a modified process, the solvent is sprayed upon the mixt. of bitumen, etc., and mud after the mud has been spread upon the road and when substantially all the  $\text{H}_2\text{O}$  has evapd. therefrom.

**Roofing and like materials.** D. L. IRWIN and E. R. JAMES. *Brit.* 121,205, Dec. 21, 1917. A layer of flexible roofing material, such as tarred felt, is combined with a non-metallic supporting material, such as strawboard, etc. The compd. sheet is rigid, so that it can be applied to the rafters, etc., without any support. The strawboard, etc., may be waterproofed, and the edges of the sheets may be coated with waterproofing material. Cf. 25,589, 1901.

**Heat-insulating building material.** H. CASTOR. U. S. 1,288,834, Dec. 24. Infusorial earth cut from natural deposits is heated to about 1000° to improve its resistance

to handling and the product is then cut into shapes for use as a heat-insulating or building material.

## 21. FUELS, GAS, TAR AND COKE.

J. D. PENNOCK.

**Oxidation and ignition of coal.** RICHARD V. WHEELER. *J. Chem. Soc.* 113, 945-55(1918).—It was found, in conformity with the results of previous investigations, that the absorption of O by newly won bituminous coal is initially very rapid, even at ordinary atm. temps., but that this rapid absorption soon gives place to a slow but long continued absorption. The initial rapid absorption of O at low temps. is not accompanied, so far as could be ascertained, by the formation of water or the oxides of C, but during the second or slow phase of the absorption these products of oxidation of the coal substance make their appearance, the amts. increasing with the temp. of the coal. For a given coal at a given temp. the ratio  $\text{CO}_2/\text{CO}$  in the products of combustion remained appreciably const. throughout the period of long-continued slow absorption of O, the ratio decreasing with increased temp. The following hypothesis was advanced as an interpretation of the results of the research work which had been finished at that time: The reaction responsible for the self-heating of coal is mainly one of attachment of O to mols. of high C content. Subsidiary to this reaction, but playing an important role in detg. the actual spontaneous ignition of coal, is a chem. interaction between the O thus loosely held, with the C-like conglomerate. J. H. YOUNG.

**Method of least squares applied to estimating errors in coal analysis.** J. D. DAVIS AND J. G. FAIRCHILD. *Bur. Mines, Tech. Paper* 171, 36 pp.(1918).—The method of least squares has been applied to estg. the probable limits of error in analyzing samples of coal and it is shown how this method should be applied. The results obtained through the application of the theory of probability would seem to indicate rather clearly what degree of precision may be expected with the coal analysis when the quantities are defined by the actual methods used for the analysis. When the error corresponding to a probability of  $1/2$  is taken, the errors involved in sampling and analyzing coal may be taken to be as follows: In taking the 5-lb. gross sample, about 0.04% of sample is ash in the analysis because of failure to include or exclude impurities represented; in the ash detn. 0.08%; in the moisture detn., 0.04%; in the volatile-matter detn., 0.15%, and in the heating-value detn., 0.15%. Combining these possible errors makes a possible error in calcg. the heating value of coal substance of about 0.18% of the heating value. Now the limit detg. rejection is often taken as the error whose probability is 1 in 1000, which is 4.9 times (or roughly 5 times) the probable error of a single detn.; the outside limit for error in the above detns. may be easily calcd. The limits of error would then be as follows: For sampling, 0.20%; for the ash detn., 0.40%; for the moisture detn., 0.20%; and for the heating-value detn., 0.75%. J. H. YOUNG.

**Distillation of coal at low temperatures.** ANON. *Genie civil* July 7, 1917; *Chem. Met. Eng.* 20, 78-9(1919).—When the distn. of coal is carried out at low temps., it is possible to ext. from the coal all the industrial products of petrol; paraffins, lubricants, benzines and oils. In other words, the distn. products may consist largely of either the paraffin hydrocarbons or of the aromatic hydrocarbons, depending upon the temp. and pressure at which the coal was distd., low temps. being favorable for the formation of the paraffin hydrocarbons. J. H. YOUNG.

**Combustion of lignites and high-moisture fuels.** T. A. MARSH. *Elec. World* 73, 265-7(1919).—Typical analyses of high-moisture fuels of the U. S. and Canada and a summary of experience derived from burning these fuels in power plants. C. G. F.

**Fuel-burning equipment of modern power stations.** JOSEPH G. WORKER. *Elec. J.* 16, 55-60(1919).—A study of the equipment of most modern plants. Numerous analyses of coals and diagrams are included. Of particular interest to the chem. engineer. C. G. F.

**Fuel economizers.** C. V. BOYS. *Nature* 102, 249-50(1918).—For the purpose of increasing the heat efficiency of the domestic fire grate an economizer has been devised in which the flue-gases are diverted on their way to the chimney through 2 upright cylinders standing on each side of the fire place, each cylinder surrounding a concentric pipe which is open above and below. The flue-gases pass through the annular space thus formed on their way to the chimney heating the inner tube and causing a current of warm air to be discharged into the room; also the surrounding air is warmed by contact with the exterior of the flue-gas chambers. The fire remains visible and radiates as usual. JOHN AITKEN. *Ibid* 102, 285(1918).—An outline is given of a fuel economizer that was designed to increase the efficiency of the open fire-grate, but owing to the rapid accumulation of soot it was found to be impractical, and a similar drawback was predicted for the economizer designed by Boys. The objectionable appearance of economizers may be improved by painting them with suitable colors, and it is claimed that all paints, with the exception of Al, rank equally well for heat of wave lengths given out at the temps. employed. C. V. BOYS. *Ibid* 102, 285(1918).—It is pointed out that in the economizer designed by the author the trouble of cleaning is only a minor inconvenience, and provision to make this easy is incorporated in the design. J. A. HARKER. *Ibid* 102, 324(1918).—Exptl. evidence is given in support of the view advanced by Aitken that the color of a hot surface at relatively low temp. has very little influence on the amt. of radiation leaving it. For temp. differences in the region of 100°, it was found that a bright surface of ordinary tin-plate gave off an amt. of radiation equal to only 5-10% of that from a black body. Burnished Cu well cleaned with metal polish gave a lower intrinsic radiation than Sn. A coat of almost any paint, however, regardless of color brings the true radiation up to from 80 to 90% of that of a black body, and a layer of paper varnish, or of celluloid varnish so thin and transparent as to be almost imperceptible has almost the same effect. With Al paint the pure radiation is reduced to from 40 to 55% of that of a black body. It has been found also that in the case of low-pressure steam radiators in the region of 100° almost exactly half the heat leaving the vertical surfaces, if these are of an ordinary character or painted in the usual manner, consists of pure radiation, the remainder being the combined effect of conduction and convection. If the radiators are metallized by painting with Al paint, the amt. of heat reaching the middle of a room warmed by such radiators would be lowered to one-half, or double the amt. of heating surface would be required to produce the same radiation effect as if the surface were black or of bare metallic Fe. R. C. PARSONS. *Ibid* 102, 324-5(1918).—A description is given of an app. for economizing fuel that has been in operation for the past 20 years without causing any trouble, or requiring any repairs. JOHN AITKEN. *Ibid* 102, 346-7(1919).—Fuel economizers may be used in connection with stoves as well as with open fire-grates and in this way much better heating is obtained with a greatly reduced consumption of fuel.

W. H. ROSS.

**Blue water gas in conjunction with benzene recovery.** E. F. KEABLE. *Gas World* 69, 183-4(1918); *Gas J.* 144, 77-9, 120-1(1918).—The plant described is the "K. and A." Smith's modification. The arrangement, design of plant, and method of operation are given in detail. Some working results are: sp. gr. of blue water gas 0.6, S content 113 grains per 100 cu. ft., cal. value 331 B. t. u., fuel consumption 29.8 lbs. per 1000 cu. ft. of blue water gas, benzene recovered 1.79 gals. per ton of coal. With this plant clinkering troubles are reduced, heat is given up by the blue water gas to

the cool coke, the gas leaves the plant freed from dust, and the content of  $\text{CO}_2$  is low. K. is convinced that a combination of horizontal retorts worked in conjunction with blue water gas, would prove the solution not only of cheaper gas and the conservation of coal but would give to the gas-consuming public a gas in every way suitable for modern requirements.

J. L. WILEY.

**Reinforced concrete purifiers at Tottenham.** A. E. BROADBERRY. *Gas J.* 144, 657(1918); cf. *Ibid* 138, 485.—A novel use of reinforced concrete for overhead purifiers. The concrete was treated with "Ironite" to make it gas-tight. The purifiers have been in use for 1 yr. No defects have developed and their operation is satisfactory, particularly since their cost was barely one-half of what it would have been if cast-iron had been used.

J. L. WILEY.

**Gas economies with special regard to carbonization and the treatment and disposal of residual products.** JAMES DICKSON. *Gas J.* 144, 187-9(1918).—This paper contains some practical comments on steaming of retorts and the precautions to be taken. By steaming vertical retorts of the continuous-intermittent type a yield of 16,193 cu. ft. of gas per ton of coal was obtained with an av. cal. value of 450-460 B. t. u. after oil washing. An av. % compn. showed  $\text{H}_2$  50.8,  $\text{CH}_4$  19.7, unsatd. hydrocarbons 2.2,  $\text{CO}$  14.1,  $\text{O}_2$  0.8,  $\text{CO}_2$  5.6,  $\text{N}_2$  6.8. The coal passes the "sticky" stage sooner and the yield per unit of plant is increased by the last remains of volatile matter being pushed out by the action of the steam. Practical comments are made on recent progress in coke manuf., boiler firing, and fuel economy, intensive production of  $\text{NH}_3$  by steaming, tar dehydration and benzene recovery.

J. L. WILEY.

**Results with and without steaming in continuous vertical retorts compared.** JOHN WEST. *Gas World* 69, 180(1918).—Respective results with and without steaming in Glover-West retorts at Uddingston Gas Works. Number retorts required to make 350,000 cu. ft. daily 4-10, gas per ton of coal 25,273-11,450 cu. ft., av. cal. value (stripped) 460 B. t. u., (not stripped) 560 B. t. u., coke sold per ton 8.53-9.25 cwt., tar and light oils per ton 24.6-14.5 gals.,  $(\text{NH}_4)_2\text{SO}_4$  52.86-30.5 lbs.

J. L. WILEY.

**Use of gas coal in water-gas sets presents disadvantages, but shows money saving in cost of make.** A. C. HOWARD. *Am. Gas Eng. J.* 109, 385-6(1918).—The Union Gas and Elec. Co., Bloomington, Ill., has been using for several months Indiana gas coal instead of coke for making water gas. There is indicated a considerable saving both in gas oil and in fuel, the total net saving per day for May being \$71.21 with an av. production of gas of 571,000 cu. ft. The chief disadvantages are a reduction to about 70% of the set capacity on good coke, the escape of a yellowish gas from the stack when blasting, the presence of gas on the operating floor, and burning gases at the coaling door when charging the generator. There were used 2.68 gals. of oil per 1000 cu. ft. of 572 B. t. u. gas produced. The operating cycle and general method of handling are not sufficiently different from ordinary coke operation to warrant discussion. The set is operated on 100% coal except that when starting coke is used.

J. L. WILEY.

**Effect of direct and indirect ammonia recovery upon other by-products, and some of the advantages to be made use of.** THOMAS B. SMITH. *Gas World* 70, (Coking and By-products Sec.) No. 1798, 12-4(1919); *Gas J.* 144, 661-2(1918).—The direct system is as yet the nearest step the coke-oven industry has taken toward the idealist's "fractionation of the hydrocarbons in the tar main." The tar is brought down at a temp. considerably above the dew-point of many of the hydrocarbons, which in consequence are dephlegmated free from the heavier constituents. But many of the possible advantages of this have been neglected, with the result that a good deal of work is unnecessarily imposed on the benzene rectification plant. The clean-cut in the condensation of the hydrocarbons naturally has a drastic effect upon the tar, the viscosity of

which is so great that in cold weather it is more like pitch; and where it has to be loaded into tanks there has to be a constant addition of thick oil from the benzene plants. Upon distn. only a negligible quantity of benzene and pyridine bases are obtained. The yield of phenolic compds. is also very poor. The pink coloration of  $(\text{NH}_4)_2\text{SO}_4$  is due to the cyanogen compds. and is peculiar to the direct process. The  $\text{NH}_4\text{CNS}$  formed by the water vapor,  $\text{NH}_3$  and  $\text{CS}_2$  in the gas forms in the saturator a compd. with iron, probably an impurity in the acid. An apparently white salt is obtained which, however, colors quickly on exposure to the air, due to the presence of slight traces of a blood-red  $\text{Fe}(\text{CNS})_3$ . The coloration is intensified if more ferric salt is added, this salt being gradually formed from the oxidation of the slight traces of  $\text{FeSO}_4$  always present in com.  $(\text{NH}_4)_2\text{SO}_4$ . Naphthalene trouble on the cooling plant with the direct process is very great, but by using a suitable preventative the condenser can be kept clean for as long a period as with the indirect process. In regard to benzene recovery, S. thinks that the Simon-Carves plan is unique in its method of raising the strength of the benzene while completely stripping the oil. Complete denudation is effected in the still, the light vapors being dephlegmated from the creosote, naphthalene, cresols, heavy naphthas, and the bulk of the condensed water, in a primary condenser, the outlet temp. of which is maintained at about  $92^\circ$ . The intermediate substances are led to a sepg. tank, and will be found to include from 7 to 10% of phenolic compds. It is considerable of a com. proposition also now to recover cyanogen from coke-oven gas. The Bueb process appears to be the most effective. This involves the scrubbing of the gas before it enters the  $\text{NH}_3$  saturator with a 25-30% soln. of  $\text{FeSO}_4$ , which combines with the cyanogen,  $\text{H}_2\text{S}$  and  $\text{NH}_3$ , the ultimate products being the double ferrocyanide of  $\text{NH}_3$  and  $\text{Fe}$ , and a proportion of  $(\text{NH}_4)_2\text{SO}_4$ . By recovering the cyanogen after passing through the saturators, ultimate products can be obtained of greater purity than those obtained in the indirect process.

J. L. WILEY.

**Fine coal washing for coke in South Wales.** ANON. *Gas World* 69 (Coking and By-products Sec.), No. 1785, 16(1918).—In connection with the colliery and by-product coking works of the Glamorgan Coal Co., at Llwynypia, a Draper installation for the washing of fine coal has been in use successfully for some months. The plant deals with 30 tons of material per hr., consisting of slurry from the main washery, dust from the coal screens, and sweepings from other sources. After washing this material goes to the coke ovens with a relatively low ash content, and with not more than 8% moisture, and gives an excellent coke with not more than 7.5% total ash. The system is also applicable to washing of sizes up to nuts. The plant is described in detail by aid of diagrams.

J. L. WILEY.

**Carbonization of wood in the Stockholm gas works.** ANON. *Gas Age* 43, 74-6 (1919).—In order to det. whether or not wood could be used as a substitute for coal for gas-making, tests were carried out in inclined retorts. Bundles of wood in 3-ft. lengths were charged into the upper half of the retort, the lower half being left full of red-hot charcoal for the purpose of reducing the high content of  $\text{CO}_2$  to  $\text{CO}$ , and a small amt. of coal was used in the upper end to cause graphitization in the retorts for the purpose of sealing them and also to furnish  $\text{NH}_3$  for neutralizing the acetic acid in the wood gas. Each charge consisted approx. of 110 lbs. of wood, and 11 lbs. of coal charged about every 2-3 hrs. The temp. of the retort was about  $1200^\circ$ . Tabulated results show that the gas recovery with moist wood as well as its cal. value decreases with increasing % of moisture whereas with dry wood the contrary is true although not uniformly due probably to secondary reactions. Without a reducing charge the gas recovery diminishes by almost one-half. The sp. gr. of the gas is high, due to the high content of  $\text{CO}_2$  which decreases with the decrease in moisture. Three distns. were made with a reducing charge with moisture contents of, resp., 16, 25, and 35%, and one without with a mois-

ture content of 19%. The % compn. of the gas produced in each distn., resp., are: CO<sub>2</sub> 11.4, 14.2, 16-15.8; heavy hydrocarbons 1.9, 1.2, 1.8-2.1; O<sub>2</sub> 1.8, 2.1, 1.3-1.3; CO 21.9, 26.1, 21.8-23.6; CH<sub>4</sub> 14.9, 8.2, 9.1-14.5; H<sub>2</sub> 46.5, 44.5, 47.1-39.2; N<sub>2</sub> 1.6, 3.7, 2.9-3.5. The charcoal production from dry wood was for each distn., resp., 23, 18, 16-19%. In firing tests it was found that the mixt. of charcoal and coke could be used for heating the retorts provided the air supply was properly adjusted.

J. L. WILEY.

**Modernization of plant.** H. C. WIDLAK. *Gas J.* 144, 171-3, 232-4, 301-2 (1918).—Experiences in altering retort-house machinery without holding up operations.

J. L. WILEY.

**Koppers chamber ovens for coal-gas manufacture.** K. BUNTE AND E. TERRES. *J. Gasbel.* 61, 433-6, 445-50 (1918); *Gas J.* 144, 661 (1918).—A series of efficiency tests carried out in 1912 at the Vienna-Leopoldau Gas Works on the Koppers system of chamber ovens. The plant consisted of 72 chamber ovens in ranges of 9, 5 of which were working during the test. \* Each chamber was 10.3 m. long by 540 mm. broad at the discharging end, tapering to 480 mm. at the charging end. The cold producer gas and secondary air were heated by the waste gas in 4 regenerators built under each oven. The producer gas came from an external Kerpely-Marischka plant consisting of 12 producers, 5 of which were at work. The water-jacket steam boilers on these producers generated the necessary steam. The vol. of producer gas made was calcd. on a carbon balance sheet obtained from analyses. It was shown by one test that 11.17 kg. of coke were burned in the producer during the carbonization of 100 kg. of coal and that 663 cal. had to be supplied as producer gas to the ovens to carbonize 1 kg. of coal. The percentage compn. of the producer gas was: CO<sub>2</sub> 3.65, O<sub>2</sub> 0.2, CO 29.12, H<sub>2</sub> 9.88, CH<sub>4</sub> 0.2, N<sub>2</sub> 56.95. The thermal balance sheet showed that the heat doing useful work in the ovens amounted to 71.1% of the heat of combustion of the coke used in the producers, whereas the producer gas itself contained 81.6% of the heat of combustion of the coke used in its production. The difference represents the heat lost in the waste gases and by radiation.

J. L. WILEY.

**Inclined chamber ovens at Auburn Junction.** C. E. REESE AND F. W. SEYMOUR. *Gas Age* 43, 80-3 (1919).—A description of installations of Russell Engineering Co.'s inclined slot ovens at Auburn Junction, Ind., and Battle Creek, Mich. The ovens are each 19.5 ft. long and built of silica materials. Producer gas is generated for heating the retorts, and recuperative heating is employed. Provision is also made for steaming under the grates with the object of preventing clinkers and reducing fuel consumption. Operation results for the month of March in 1 setting of 3 slots at Auburn Junction show an av. of 173.4 thousand cu. ft. of gas daily, 5.81 cu. ft. of gas per lb. of coal carbonized, 6690 lbs. of coke generator fuel used per day, 467 lbs. of generator fuel per ton of coal carbonized, 40 lbs. of generator fuel per 1000 cu. ft. of gas made, 5.7 ovens charged per day, and 5200 lbs. of coal per charge. This installation resembles the coke oven in that the charges are larger and the coking period is longer than in the usual gas bench practice. At Battle Creek tests of the raw gas indicate yields of 5.5 lbs. NH<sub>3</sub> and 11 gals. tar per ton of coal.

J. L. WILEY.

**New coke-fired German gas producer.** ANON. *Stahl u. Eisen*, March 7, 1918; *Iron Age* 103, 180-1 (1919).—A type of tapping gas producer similar in design to a small blast furnace with a vertical shaft and narrowed hearth, charging hopper and cone, and using coke exclusively. It has been in operation for 2 yrs. The producer is arranged with tapholes because the ash of the coke is changed into slag by means of charges of mixer slag or basic open-hearth slag, or mixts. of the two. The iron is reduced and obtained as a pig-iron high in Mn and P. No steam is used nor is there any heating of the hearth. The blast heated to 55-70° has a pressure of 9.1 oz. per sq. in. It is

distributed from the bustle pipe to 6 water-cooled tuyères. The gas produced known as dry-gas has the following analysis:  $\text{CO}_2$  0.30-0.70%,  $\text{CO}$  33-33.5%,  $\text{CH}_4$  1.2-1.3%,  $\text{H}_2$  0.10%, S 0.122 grains per cu. ft., moisture 5.24 grains per cu. ft., dust 0.73 grains per cu. ft., sp. wt. 0.91-0.94, cal. value 127 B. t. u., temp. attained by burning  $85^\circ$  higher than ordinary coal producer gas. The gas is practically free from tar, there is no loss of C through the formation of tar, and all the C in the coke is gasified. With an av. C content of 86-88%, each kg. of coke gives 4.8-5 cu. m. of gas, whereas in usual producer practice 1 kg. of coke gives 4.4 cu. m. Except for the hearth lining which needs renewal about every 13 months, the producer requires little repairs.

J. L. WILKY.

**Refractory materials in gas-works, from a user's point of view.** JNO. P. LEATHER. *Trans. Eng. Ceram. Soc.* 17, 246-7(1918).—See C. A. 12, 1824. C. H. KERR.

**Corrosion of dry gas meters.** J. G. TAPLAY. *Gas World* 69, 230-1(1918); *Gas J.* 144, 359-62(1918).—An examn. of the liquor found in a meter showed it to consist of (1) an oily part containing 94.5% unsatd. hydrocarbons together with resins and naphthalene, 5% pyridine bases and 0.5% paraffins, (2) an aq. part containing pyridine bases,  $\text{FeSO}_4$  and  $\text{Fe}_2(\text{SO}_4)_3$ ,  $\text{Fe}(\text{CNS})_3$ ,  $\text{NH}_4\text{CNS}$ ,  $(\text{NH}_4)_2\text{S}_2\text{O}_8$  and leather residue, (3) a solid part containing 91% leather substance, 8.5%  $\text{Fe}_2\text{O}_3$ ,  $\text{Fe}_2(\text{SO}_4)_3$ ,  $\text{Sn}(\text{SO}_4)_2$ ,  $\text{ZnSO}_4$ , and 0.5% free S. Further investigation recorded the effects of the solns. of salts on tinned sheet-iron, and on undressed and dressed meter leathers, left in contact for 4 hrs. **Tinned Sheet Iron:**  $(\text{NH}_4)_2\text{SO}_4$  and  $(\text{NH}_4)_2\text{S}_2\text{O}_8$  appear to be more active than  $\text{NH}_4\text{CNS}$ . Only the 2 latter salts dissolve the  $\text{Fe}_2\text{O}_3$  formed and liberate the  $\text{NH}_3$  which can combine with a further quantity of  $\text{CS}_2$ .  $(\text{NH}_4)_2\text{SO}_4$  appears to produce more perforation of the sheet-iron than do other  $\text{NH}_4$  salts, probably because of the greater galvanic action set up. With aq. soln. of pyridine bases, no corrosion is likely to occur. This applies also to a soln. of  $\text{Fe}(\text{CNS})_3$ . Moist  $\text{SO}_2$  is very destructive both toward sheet-iron and the brass parts of the meter, converting them into sulfites and sulfates. **Undressed Leather:** Solns. of  $\text{NH}_4\text{CNS}$ ,  $(\text{NH}_4)_2\text{S}_2\text{O}_8$ , pyridine bases,  $\text{Fe}(\text{CNS})_3$ , remove tannin and lime, and the 3 former remove  $\text{Fe}_2\text{O}_3$  from leather. With regard to the sediments containing leather substance, solns. of  $\text{NH}_4\text{CNS}$ ,  $(\text{NH}_4)_2\text{SO}_4$ , pyridine bases and  $\text{Fe}(\text{CNS})_3$  cause this sediment to be produced, while  $(\text{NH}_4)_2\text{S}_2\text{O}_8$  does not. A mixed soln. of pyridine bases and  $\text{NH}_4\text{CNS}$  produced more sediment than each of these alone. Moist  $\text{SO}_2$  causes the rotting of leather. The mixed liquor produced by the action of  $\text{CS}_2$  with  $\text{NH}_3$  also contained a leather substance; the filtered liquor contained tannin,  $\text{Fe}_2\text{O}_3$ , lime and soluble leather substance. **Dressed Leather:** Solns. of  $\text{NH}_4\text{CNS}$ ,  $(\text{NH}_4)_2\text{SO}_4$ ,  $(\text{NH}_4)_2\text{S}_2\text{O}_8$ , pyridine bases, and  $\text{Fe}(\text{CNS})_3$  remove the oil-dressing from leather.  $(\text{NH}_4)_2\text{SO}_4$  removes the least, and  $\text{Fe}(\text{CNS})_3$  the most. After removal of the oil-dressing, solns. of  $\text{NH}_4\text{CNS}$ , pyridine bases, and  $\text{Fe}(\text{CNS})_3$  contained a sediment of leather substance. Solns. of  $(\text{NH}_4)_2\text{SO}_4$  and  $(\text{NH}_4)_2\text{S}_2\text{O}_8$  contained no sediment. All the filtered liquors except  $(\text{NH}_4)_2\text{SO}_4$  contained tannin,  $\text{Fe}_2\text{O}_3$  and lime derived from leather. Benzene was found to retard the action of a moist mixt. of  $\text{CS}_2$  and  $\text{NH}_3$  upon meter materials. In many meters which failed to register correctly the fault was attributed to the presence of a resinous material on the valve. A cure for corrosion is suggested by reference to meters which had become coated with paraffin due to the spraying of the gas with paraffin oil for naphthalene prevention. T. remarks that there seemed to be no doubt that this oil had preserved the metal parts and the leathers from corrosive action, for when the meters were opened after service of from 5-14 yrs. the metal parts and leather were in an excellent state of preservation. This paraffin oil spray also kept the valves lubricated and the meters in proper working condition. The method has been permanently adopted at the Hagerston Meter Works for preserving the meters.

J. L. WILKY.

**Unaccounted for gas.** B. R. PARKINSON. *Gas World* 69, 228-30(1918); *Gas J.* 144, 362-9(1918).—Gas losses are due to 3 causes: (1) Corrections for temp., condensation and pressure, 0.75%; (2) leakage, 1%; (3) measurement, 5% with an added 0.25% for fast station meters. P. discusses also the practical application of spraying meters for preserving them from corrosion. The immediate effect is to clean the slide valves, ultimately to soften the leathers and restore the mechanism to a normal working. The app. used is the same as for spraying paint. One gal. of oil will spray 100 meters. The oil used is the same as for gas-making. A heavy mineral oil is equally effective, or hot paraffin vapor may be used. A considerable saving is possible in meter repairs and gas leakage.

J. L. WILEY.

**Coal tar as a key industry.** ALFRED BURTON. *Can. Chem. J.* 3, 58-9(1919).

E. H.

**Plant of the Seaboard By-product Coke Company.** D. MACARTHUR. *Gas Age* 43, 1-6, 69-73(1919).—Description of a Koppers installation which is said to represent the latest developments in coke oven practice. The article is illustrated. Seventy-two % of the by-product ovens in the country are Koppers ovens, capable of carbonizing 33 million tons of coal per yr. and of producing 24.75 million tons of coke. The products of this plant are coke, gas, tar,  $(\text{NH}_4)_2\text{SO}_4$ , benzene, and naphthalene. The installation consists of 165 ovens or 3 batteries of 55 ovens each. One battery is the Koppers standard horizontal cross-regenerative by-product coke oven type, the other 2 the horizontal cross-regenerative combination type. The ovens are designed for 15-hr. coking time, each having a capacity of 12.5 tons, and being 37.5 ft. long by 10 ft. high by 18.25 in. av. width. Silica brick are used throughout for the oven walls and heating flues. With 165 ovens carbonizing on 16.5 hrs. coking time, there is a daily capacity of 3,000 tons of coal, yielding 2,200 tons of coke, 16.5 million cu. ft of surplus gas of 610 B. t. u. quality, 75,000 lbs. of  $(\text{NH}_4)_2\text{SO}_4$ , 24,000 gals. tar and 10,000 gals. light oil. The company is producing a motor fuel called B-zol. It is said to yield about 20% more power and 15-25% more mileage than gasoline. Since the fuel has been introduced in the market, the demand for it promises to exceed greatly the supply. The plant is equipped to make 350,000 gals. of B-zol per month.

J. L. WILEY.

Hydraulic separation as applied to the recovery of fine coals, shales and clays (DRAPER) 1. Corrosive action of flue dust on fire-bricks (MELLOR) 19. Photometric apparatus (TROTTER) 1.

**GUIEU, PIERRE:** *La tourbe, Prospection, Extraction, Traitement, Utilisation.* Paris: Garnier frères, 6 rue des Sts-Pères. 220 pp. 3 francs. For review see *Rev. sci.* 56, 606(1918).

**Artificial fuel.** L. LE W. HAMON. *Brit.* 121,102, Aug. 20, 1918. Lignite, peat, sod, leaf mold, or shale, or two or more of these raw carbonaceous materials are mixed with cellulose material, such as sawdust, silica, alkali, and tar or pitch, or residues from tar or pitch, or residues from the distn. of oils, and the mixt. is molded into blocks. Other carbonaceous materials, such as graphite, anthracite, or coal dust, coke breeze, or culm and mineral substances, such as Fe and Mn ores, may be added. A smokeless fuel can be obtained by coking the blocks in the usual way in retorts.

**Briquets.** C. H. SMITH. *Brit.* 120,585, Aug. 29, 1917. Briquets are made from mixts. of raw coals, raw coal and coke, or raw coals and a hydrocarbon binder such as coal-tar pitch, asphalt pitch, coal-tar or petroleum oils, the mixt. being such that the volatile matter contained therein is between 11 and 17%. The mixt. is made into a

mash with  $H_2O$ , or by the aid of the binder, the whole being well crushed. The mixt. is then molded into briquets, and these are carbonized in a chamber which is maintained at a temp. between  $1400$  and  $2000^\circ F.$ —preferably at about  $1850^\circ F.$ —the by-products being collected. It is stated that the briquet produced is hard and porous, burns with a non-smoky flame, and has a volatile content of about 2.5%. Cf. 111,285 (C. A. 12, 627.)

**Motor spirit.** J. PENHALE. Brit. 120,792, Dec. 3, 1917. A motor spirit consists of a satd. soln. of  $C_2H_2$  in alc. with the addition of acrolein as a denaturant.

**Treating gases.** W. G. LEAMON. Brit. 120,554, Sept. 25, 1918. In a process of eliminating  $H_2S$  from natural gas, coke-oven gas, producer gas, illuminating gas, or the like, the gas, preheated to about  $300^\circ$ , is supplied with a small quantity of air sufficient to oxidize the H of the impurity but not necessarily the S, and is passed over heated pumice, fire-brick, broken pottery, or the like, wherein the oxidation occurs. Proceeding immediately to cold scrubbers or absorbs the S vapor is condensed or fixed. The pumice, etc., may carry metal catalysts as Pt, Ni, or the like. The operation may be conducted with the gas at delivery or enhanced pressure. The preheater comprizes a folded Fe pipe in a jacket or furnace, the oxidizer comprizes a folded Fe pipe in a jacket or furnace and the oxidizer comprizes an Fe U-tube fitted with the pumice in a furnace.

**Coke.** A. McD. DUCKHAM. U. S. 1,289,045, Dec. 24. The pat. relates to a method of heating coal in vertical retorts to effect coking.

**Cooling coke, etc.** B. E. D. KILBURN. Brit. 120,329, Mar. 7, 1918. Hot residues from distn. processes, such as coke, are cooled by the repeated circulation through them of a body of air, the O of which is taken up in the early stages of the process. The app. is specified.

---

## 22. PETROLEUM, ASPHALT AND WOOD PRODUCTS.

---

F. M. ROGERS.

**The Russian petroleum industry and its prospects.** D. GHAMBASHIDZE. *J. Inst. Petroleum Tech.* 4, 158-88(1918).—A statistical review. F. W. SMITHER.

**The Scottish mineral oil industry.** ANON. *J. Soc. Chem. Ind.* 37, 467-8R(1918). E. H.

**Gasoline plants and their operation.** G. A. BURRELL. *Oil & Gas J.* 17, No. 36, 54-6(1919).—The first essential is clean gas-gathering lines with care observed in having all joints tight. Air which leaks into the system not only may be dangerous but also makes a greater pressure necessary to remove gasoline. The most effective pressure and temp. for each particular plant should be detd. by test. Cooling water should always be dropped in thin sheets to get best radiation and evapn. Good results are obtained using expansion engines, and artificial cooling is coming into greater favor. Direct cooling of the residual gases with brine holds possibilities. Mineral seal oil is still considered best for absorption and vertical absorbers with minimum height of 35 ft. are better than horizontal. For gas containing up to 1 gal. per 1000 cu. ft. the absorption plant is most effective, but compression may be used above that point or a combination of both methods. The gasoline content of inlet and residual gas should be detd. regularly, and meters also checked up occasionally. The use of vacuum pumps is not recommended unless exptl. data have shown they increase the yield. The simple rule for blending is as follows: "blend as soon after making, and with as little agitation and exposure to air as possible, using proportions as detd. by experimentation."

R. R. MATTHEWS.

**Physical tests of gasoline.** J. F. NEWTON AND F. N. WILLIAMS. *Petroleum Age* 6, No. 2, 41-4 (1919).—Distn. is the most important as it indicates clearly the quality of the gasoline. The initial b. p. is the temp. at which the first drop of condensate falls from the condenser. The final b. p. is the highest temp. reached in distg. a sample to dryness. Tagliabue's app. is used for gasoline distn. and 5% temp. readings are made. The "doctor test" (i. e., test for S compds.) is next in importance to distn. The gasoline is thoroughly shaken with a soln. of sodium plumbite and a small quantity of flowers of S is added. If neither the gasoline or S is discolored the "doctor test" is satisfactory. The color is now generally taken with some type of colorimeter and not in a 4-oz. bottle. D., odor, % water, and foreign matter, chill test and calorific value are also taken up, but are minor considerations. With casing-head gasoline the detn. of vapor pressure is of importance because of shipping restrictions. The standard method of taking vapor pressure is shown. Gasoline specifications of U. S. Government for motor gasoline are as follows: Initial b. p. not over 140° F., 20% off at 221° F., 45% off at 275° F., 90% off at 356° F., and final b. p. not over 428° F. Domestic aviation must have 5% distd. between 122° F. and 157° F., 50% off at 221° F., 90% off at 311° F., and 96% off at 347° F. This means a gasoline having a final b. p. approx. 370° F. Export aviation gasoline must have 65% off at 212° F., 87% off at 240° F., and final b. p. not over 302° F.

R. R. MATTHEWS.

#### Transformer oils (ESCHHOLZ, PHILIP) 4.

---

HAGER, DORSEY: *Practical Oil Geology*. 3rd Ed. New York: McGraw-Hill Book Co., Inc. 243 pp. \$2.50. For review see *Mining Sci. Press* 118, 234 (1919); cf. C. A. 9, 1891; 11, 3117.

**Distilling petroleum oils.** L. O. SHERMAN. U. S. 1,288,711, Dec. 24. In distg. petroleum oils to obtain products of low b. p., the oil is heated under pressure to vaporize a portion of it, the higher boiling portions of the distillate are condensed and this condensed portion of the distillate is mixed with a portion of oil from the still and heated under a pressure above that of the initial vaporization to obtain low-boiling products. The pat. illustrates and describes an app. for carrying out this procedure.

**Apparatus for distilling and refining petroleum oils.** H. C. LEEFE. U. S. 1,288,934, Dec. 24.

**Distilling hydrocarbons, etc.** C. TURNER. Brit. 120,854, Nov. 23, 1917. In the fractional or destructive distn. of hydrocarbon oils or other liquids, the pressure in the still is raised and lowered alternately. The still is closed to raise the pressure, and is opened to lower the pressure rapidly solely by expansion of the vapors. The operation is effected without intermittent cooling, except such as may occur during the lowering of the pressure. In distg. hydrocarbon oil, pressure steam is blown into the oil until the pressure reaches 5 lbs. per sq. in. The vapor outlet is then opened until the pressure falls to 2 lbs. per sq. in. whereupon the vapor outlet is closed and steam is again admitted. The operation is continued until the steam, which is of 20 lb. pressure, no longer effects distn.; after this stage, superheated steam is used.

**Vaporizing oils.** C. B. FORWARD. Brit. 120,626, Nov. 15, 1917. Oils are vaporized or gasified by injecting oil vapor and steam into one of three tubes which are connected together and are heated in a furnace, the tubes being surrounded by outer tubes which contain superheated steam. The vaporizing tubes are connected by U-bends arranged in an air-tight manner, and the outer and inner tubes are connected together in a manner which permits of unequal expansion of the tubes without loss of air-tightness in the connection.

**Purifying acetates, etc.** SOCIÉTÉ E. BARBET ET FILS ET CIE. Brit. 120,558, Oct. 9, 1918. Crude aq. acetates obtained by wood distn. are purified from tar by treating them with an org. solvent for tar which is insol. or only slightly sol. in  $H_2O$ . The preferred solvent is cresol; benzene hydrocarbons, carbolic oils, naphthols, petroleum spirit, turpentine spirit, Me acetate, etc., also may be used. Using the app. specified, a tower packed with porcelain balls, quartz, broken glass, coke, etc., is supplied at the bottom with cresol from a vessel and at the top with crude acetate soln. from a vessel. The purified acetate soln. is withdrawn from the bottom of the tower and the dissolved tar from the top. The tar soln. is distd. to recover the solvent of the tar. The process can be applied to remove tar from other liquids, e. g., crude acetone or  $NH_4OH$ .

**Distilling wood.** SOCIÉTÉ E. BARBET ET FILS ET CIE. Brit. 120,560, Oct. 11, 1918. App. adapted for continuous working for treating the vapors, generated in distg. wood to sep. "methylene" (presumably  $CH_2OH$ ) and to form a soln. of Na or Ca acetate free from tar. Constructional details and operation are specified.

---

### 23. CELLULOSE AND PAPER.

---

A. D. LITTLE.

**Cellulose esters.** A. DUBOSC. *Caoutchouc et gutta-percha* 15, 9501-8(1918).—A review of the work done on the nature of the reactions in the formation of nitrocellulose and cellulose acetate. D. confirms the statements of Mosenthal that materials of the same chem. compn., having different physical states or construction, produce esters with widely varying properties. JOHN B. TUTTLE.

**The Webb paper tester, a new instrument for testing corrugated fiber boards.** J. D. MALCOLMSON. *J. Ind. Eng. Chem.* 11, 133-8(1919).—The Webb tester consists essentially of a steel plunger, 0.1 in. in diam., actuated by a helical steel spring which may be compressed by means of a hand wheel operating through suitable gearing, and the deflection of the spring indicated by a dial calibrated to read in pounds per sq. in. Owing to the small test area required, it is possible to test the component parts of corrugated board, and the strength value of the board is more nearly indicated than is possible with the Mullen tester. In addition to the puncture test, the Webb machine may be used for tensile, elongation, and compression tests. R. B. ROX.

**Paper textiles.** LILLIAN B. STORMS. Iowa State College. *J. Home Econ.* 10, 451-6(1918).—A summary of the development of paper textiles. A bibliography is appended. HELEN N. ELLIOTT.

---

**Obtaining products by destructive distillation (application to soda cellulose waste liquors)** (Brit. pat. 120,724) 18.

---

**Fermenting sulfite liquors.** R. H. MCKEE. Brit. 120,520, May 15, 1918. To produce alc. from sulfite liquors containing fermentable sugars they are treated with yeast in the presence of excess  $O$ . The amt. of free  $SO_2$  in the liquor is preferably reduced to 0.35 g. per liter by boiling, blowing air through the soln. while heated, or other methods. The liquor is then brought to a temp. of  $27-8^\circ$  and yeast is added. Air is blown through the liquor while fermentation is proceeding. The liquid is then distd. to sep. the alc., alkali being added to fix the  $SO_2$ . The air used in the process is washed in unfermented liquor to recover alc. carried off by it.

**Obtaining pulp, etc., from sea tang.** V. FRYDENBERG. Brit. 120,761, Nov. 19, 1917. In prepg. sea tang, particularly *Zostera marina*, for paper pulp or for strength-

ening plaster, stucco, and the like, the whole mass, which may be bleached with Cl, chloride of lime, or the like, is dried in the air or artificially and then comminuted by ordinary crushing, rubbing, or carding processes to the required degree of fineness.

**Stencil-sheet.** J. A. AMBLER. U. S. 1,288,792, Dec. 24. A stencil-sheet is prep'd. by passing an open-texture porous paper through a soln. of gelatin and CaCl<sub>2</sub> and then through a soln. of glycerol. The sheet is tough and pliable.

## 25. DYES AND TEXTILE CHEMISTRY.

L. A. OLNEY.

**Recommendations of the tariff commission regarding dyestuffs.** GRINNELL JONES. *Color Trade J.* 4, 27-30(1919).—Address before Am. Inst. Chem. Eng. Cf. C. A. 12, 767. L. A. OLNEY.

**British scheme for state aid to dye industry.** ANON. *Board of Trade J. (Brit.)* Nov., 1918; *Color Trade J.* 4, 44-6(1919).—The object is to insure that the trade requirements of the British Empire dependent upon a supply of dyes are met within a reasonable period to an extent sufficient to make them independent of German dyestuffs, but not to assist financially the formation or development of any dye-making business in the interests of the business as such. Two kinds of assistance are proposed: (A) Loans at commercial rate of interest especially for the development of dyes which are reasonably necessary for dye users, but which are not manuf'd. at all or in any sufficient quantity. (B) Grants (1) in aid of the cost of plant and building provided, mainly for the purpose described under A, and (2) in aid of research. Such grants are not to exceed 40% of extension of lab: buildings and equipment and 40% of annual maintenance. The whole supervision and administration of these loans and grants are to be under the British Board of Trade. L. A. OLNEY.

**Dyestuff industry in France.** ANON. *Color Trade J.* 4, 47(1919).—From U. S. Consular Report. France is following the example of America and England in endeavoring to create a national chem. industry to combat the monopoly which Germany has controlled. La Compagnie National des Matieres Colorantes et des Products Chimiques with a capital of 40,000,000 francs was organized with this object in view.

L. A. OLNEY.

**The Brazilian market for aniline dyes.** ANON. *Color Trade J.* 4, 36-8(1919).—Statistics as to imports of dyes by this country, import duties, German sales systems, and the methods available for distributing dyes. L. A. OLNEY.

**Influence of dyeing and finishing processes on woven fabrics.** EBER MIDGLEY. *J. Soc. Dyers Colourists* 35, 20-3(1919).—During the dyeing and finishing processes all woven fabrics alter to some extent in appearance, handle, strength, and elasticity. The amt. of alteration is dependent on 4 factors: (1) the type and quality of the raw material or materials employed, (2) the type and structure of the warp and filling threads, (3) the structure and setting of the cloth in the loom, (4) the particular processes and degree of treatment in each to which the fabric is subjected during the dyeing and finishing. A series of tests recorded in diagrammatic form indicates that crabbing, scouring and permanent finishing attack the wool fiber to some extent, and are responsible for an appreciable amt. of tendering. While the limit has been reached in respect to the types of raw materials and the structures of yarns employed in the manuf. of textiles, there is no limitation in the mechanical treatment and manipulation, nor the chem. treatment of the materials to provide them with new and improved properties. The most serious irregularity developing during dyeing and finishing and the most difficult to account for is known as "crimps." Uneven shrinkage being the cause of

the defect indicates that it arises from an absence of uniformity in either materials or treatment in some process from fiber to finished cloth. L. A. OLNEY.

**Notes on cleaning and dyeing with volatile solvents.** H. HEGY. *J. Soc. Dyers Colourists* 35, 12-8(1919).—The use of solvent liquids in the so-called "dry," "French" or "chemical" cleansing enables the operation to be more effectively done and with far less damage than would result from use of water. The commonest solvents are petroleum, benzene and solvent naphtha. Non-inflammable solvents like  $\text{CCl}_4$  and  $\text{C}_2\text{HCl}_3$  have been suggested, but cannot be recommended if exposed to the air, as their vapors are injurious to work people and when purified by distn. they are likely to decompose if in contact with water and metals at high temps. They are also more costly. Water is slightly sol. in these solvents, and this soly. increases with temp. Such dissolved water will sep. upon cold surfaces during the cooling, and for this reason all articles must be dry before coming in contact with the solvent. Solvents containing oils and fatty acids dissolve more  $\text{H}_2\text{O}$  than non-greasy solns. "Benzine soap" dissolved in the solvent makes it capable of taking up much more  $\text{H}_2\text{O}$  and this is one of the properties which makes it valuable in dry cleansing. The  $\text{H}_2\text{O}$  contained in the volatile soln. may hold certain dyes, sol. hydroxides, water-sol. gums, and various disinfectants and the solvent acts as an inert vehicle for conveying a small amt. of very strong soln. of the substance to the material immersed in the mixed liquid. For each pound of goods cleansed something like 5 or 6 gals. of clean spirit is required but much of that used is reclaimed. The general principles involved in all systems are discussed and then detail is given in regard to the "Barbe" system, which uses a closed revolving barrel, and "Smith's" system, which uses a machine consisting of an outer casing of Fe containing the solvents and an inner cage of steel with a periphery of perforated steel plates which is carried on a strong steel shaft. The cage may be revolved in the solvent within the outer casing, or when the solvent has been withdrawn it may be revolved more rapidly and thus act as a hydro-extractor. The paper closes with a discussion of "Dry Dyeing." Cf. Fort, C. A. 13, 379. L. A. OLNEY.

**Carbonizing wool.** ANON. *Chem. Eng. Mining Rev.* 10, 23(1918).—The process consists in steeping the wool in  $\text{H}_2\text{SO}_4$ , then dry heating it to about  $100^\circ$ , after which it is passed through a burr-crushing machine. The acid is then neutralized and the wool washed. Care should be taken that the acid is not too concd., that it is applied evenly to the wool, that the temp. is not too high, or the time of treatment too long. During the heating there must be no condensation, as acid would concentrate in the moist part and injure the fiber. Neither concns., temps., nor times are stated. As about 200,000 bales of burry wool are produced yearly in Australia, a standardized process for removing the burrs is apparently needed. L. W. RIGGS.

Quinoneimide dyes (KEHRMANN, SANDOZ) 10. Medieval pigments (LAURIE) 26.

---

FORD AND LLOYD: **The Chemistry of Dyestuffs.** London: Cambridge University Press. C. F. Clay, Fetter Lane, E. C. 4. 311 pp. 7s. 6d. For review see *Rev. sci.* 56, 557(1918).

GREEN, ARTHUR G.: **The Analysis of Dyestuffs.** 2nd Ed. London: Charles Griffin & Co., Ltd., Exeter St., Strand, W. C. 144 pp. For review see *Rev. sci.* 56, 607(1918).

PERKIN, A. G. AND EVEREST, A. E.: **Natural Organic Colouring Matters.** London: Longmans, Green & Co. 28s. net. For review see *Chem. Trade J.* 64, 97 (1919).

**Dyes; dyeing.** A. M. HART. Brit. 120,588, Aug. 13, 1917. Peat is treated with  $\text{H}_2\text{SO}_4$  and  $\text{HNO}_3$ , either in admixt. or successively; the resulting acid liquid is sepd. from the fibrous residue and is used as a dye base. The liquid may be evapd. to dryness, or may be neutralized by an alk. salt and the neutral soln. crystd. The bulk of the Fe present in the acid liquid may be removed by pptn. by  $\text{K}_4\text{Fe}(\text{CN})_6$  or  $\text{K}_3\text{Fe}(\text{CN})_6$ . The acid liquid dyes yellow and brown shades, and if applied to cotton acts as a mordant for cochineal. The acid liquid or a soln. of the neutral crystals may be subjected to a process analogous to diazotization, by treating them with  $\text{NaNO}_2$ , with  $\text{HCl}$  if necessary, and treating the fiber with the resulting bath, preceded or followed by  $\beta$ -naphthol or similar azo dye component; a metallic salt, *e. g.*,  $\text{KCN}$ , may be added to the grounding bath of  $\beta$ -naphthol, etc., or the cloth may be first mordanted with a metallic salt, *e. g.*,  $\text{KCN}$  or  $\text{K}_4\text{Fe}(\text{CN})_6$ , then treated with the bath of acid liquid and nitrite and finally with a developer.

**Wool-like effects on cotton fabrics.** G. HEBERLEIN. U. S. 1,288,884, Dec. 24. Pattern effects of wool-like appearance are produced upon cotton goods by alternately treating the material with a concd. caustic alkali soln. and  $\text{H}_2\text{SO}_4$  of 49–50.5° B $\acute{\text{e}}$ . At least 3 applications of the solns. are made, followed by washing and the material is stretched during at least one of the treatments. One treatment is applied to a portion only of the fabric so as to produce pattern effects. U. S. 1,288,885 relates to a similar method except that  $\text{H}_2\text{SO}_4$  of a somewhat higher concn. is used.

## 26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN.

**Medieval pigments.** A. P. LAURIE. *J. Soc. Dyers Colourists* 35, 18–20(1919).—Historical. Mention is made of Egyptian blue (made by heating Cu or Cu ore, sand, soda and lime), ultramarine blue, purple from shell fish, gold dust, malachite green, red lead, vermillion, and orpiment. L. A. OLNEY.

**Report of sub-committee XIV on the preparation of iron and steel surfaces for painting.** ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 310–20(1918).—After one year's exposure, all the test panels (*cf.* C. A. 11, 405), which consisted of new and old steel plates which had been given various surface treatments such as pickling, sand blasting, wire brushing, etc., and then painted, were still so well protected against corrosion that no conclusions as to the relative effects of the different surface conditions could be reached. The only marked deterioration found in one set along diagonal lines was due to a process of straightening the plates during mfr. Complete data with photographs are given. F. A. WERTZ.

**Industrial colors and varnishes.** C. CLAUDIUS. *Rev. prod. chim.* 21, 170–1 (1918).—The most satisfactory protective coating to prevent the corrosion of metal products should be homogeneous and as chemically inert to the hydrolytic action of  $\text{H}_2\text{O}$  and to oxidation as possible. A bodied linseed oil containing copal and mixed with drier, thinner, and  $\text{ZnO}$  answers these requirements fairly well but is rather easily attacked by acids and fumes. The method of bodying the oil and "running" the copal are given. A paint with greater resistance is produced by using a polyterpene resin, made as follows: Treat 10 parts turpentine with one part 66° B $\acute{\text{e}}$ .  $\text{H}_2\text{SO}_4$ . Regulate the addition of acid to keep the temp. below 110°, and then agitate the mixt. for about 5 hrs. Two layers are formed. Draw off the polymer which constitutes the upper layer, wash thoroughly with  $\text{H}_2\text{O}$  and with 3%  $\text{Na}_2\text{CO}_3$  soln. to remove excess acid and organic salts such as borneol and camphene. Any emulsion formed during this process can be broken up by heating on the  $\text{H}_2\text{O}$  bath to 45–50°. The polymer

is subjected to a vacuum to remove  $H_2O$  mechanically held in the mass, and is then distd. at a pressure of 2 to 3 mm. The first fraction, coming over at  $165-175^\circ$ , is a clear liquid consisting essentially of pinene, limonene, cymene, etc.; it constitutes about  $\frac{1}{2}$  of the total product. These first fractions are repolymerized. The fraction between  $210$  and  $220^\circ$  is of a yellow color, sp. gr. 1.8 to 1.9. When the latter is mixed with copal, it produces a varnish of remarkable resistance. Best results have been obtained with a paint made of polyterpene 25%, hard copal 10%, blanc fixe 65%. This paint should be thinned with benzine, and used in several coats to get proper hiding power. F. A. WERTZ.

Some present-day aspects of the paint and varnish industry with special reference to the war. A. DE WAELE. *J. Soc. Chem. Ind.* 38, 2-4R(1919). E. H.

Report of sub-committee IX on varnish. ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 305-8(1918).—The reports of the committee members are given, on a proposed elasticity test. This test consists in "reducing" the elasticity of the varnish by adding to it a definite amt. of  $33\frac{1}{2}\%$  soln. of "run" kauri gum in turpentine, flowing the mixt. on tin plate and allowing it to dry. The amt. of reduction that the varnish will stand before the film on tin plate will crack on bending is a measure of elasticity. Details of the method are given. F. A. WERTZ.

Tentative specifications for foots permissible in properly clarified pure raw linseed oil from North American seed; serial designation D51-18T. ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 615-6(1918).—The amt. of foots shall not exceed 2% by vol. Det. foots by shaking 25 cc. of the oil at  $70-80^\circ$  for exactly 1 min. with 25 cc.  $Me_2CO$  (U. S. P.) and 10 cc. of a 10% by vol. soln. of HCl (sp. gr. 1.2) in  $H_2O$  satd. with  $CaCl_2$ . Pour the mixt. into a buret and allow to settle 24 hrs. and then read the vol. of the foots strata lying between the  $CaCl_2$  layer and the oil- $Me_2CO$  layer. F. A. WERTZ.

Report of sub-committee V on linseed oil. ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 299-300(1918).—Reports are given of the committee members on oils examd. during the year, with special reference to the foots test (see preceding abstract). F. A. WERTZ.

Tentative specifications for flash point of paint thinners other than turpentine; serial designation D28-18T. ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 685-8(1918).—The flash point shall be detd. with the Tag closed tester operated according to the specific directions given. For unofficial tests, any suitable closed type tester may be used. F. A. WERTZ.

A study of the fatty acids obtained from varnish oils and from varnishes. W. T. PEARCE. *J. Ind. Eng. Chem.* 11, 121-6(1919).—P. found that as little as 5% tung oil present in linseed oil raises  $n$  of the mixed fatty acids derived from the oils directly; but the values obtained from the fatty acids derived from varnishes were not in good agreement (cf. *C. A.* 11, 1315). Changes in  $n$  of mixts. of other oils with linseed were not appreciable. I-jelly tests (Boughton, *C. A.* 4, 2049) made on the mixed fatty acids detected 10% tung oil in linseed, 20% in soy-bean and in menhaden oil mixts., and 25% in varnishes. Results are tabulated. F. A. WERTZ.

Po-yoak oil, a new drying oil. ANON. *J. Ind. Eng. Chem.* 11, 156(1919).—Po-yoak oil, derived from a species of *Parinarium* in Sierra Leone, is pale yellow in color, contains a deposit of dark-colored "stearine," resembles tung oil in odor, and its high I no. places it in the class of drying oils. F. A. WERTZ.

Pigment containing titanium oxide. L. E. BARTON. U. S. 1,288,473, Dec. 24. Pigments of good opacity are produced by treating Ti sulfate solns. (such as those

prepd. according to the methods of U. S. pat. 1,155,462 (C. A. 9, 3369) or 1,205,144, (C. A. 11, 216) with pigment bases such as barytes, silica, china clay or asbestine and also pptg. sulfate bases in the soln. and then pptg. the Ti compds. from the soln. A composite pigment results from coalescence of the freshly pptd. particles and other added pigments.

**Coating metal surfaces.** N. C. F. JENSEN. Brit. 121,150, Nov. 6, 1917. A preservative coating is formed on metallic articles by dipping the article into an oil, e. g., a mixt. of whale oil and mineral oil, draining, and then heating to a temp. high enough to gasify the volatile constituents in an oven which permits the escape of the lighter gases. A suitable oven is one having an outlet at the top, the aperture of which can be varied, and a suitable temp. is about 300°. Cf. 2,022, 1873, 4,486, 1874, 9,570, 1888, 9,848, 1888, 1,146, 1896, 3,682, 1904, and 3,945, 1915 (C. A. 10, 2157).

**Preserving metal from rust.** W. C. A. MATH. Brit. 120,619, Nov. 14, 1917. In a process of preserving metal articles from rust by heating and immersing them in linseed oil, either alone or mixed with other substances, the linseed oil is maintained at a boiling temp.

**Resins and resinous compounds.** J. R. KOHLER. Brit. 120,729, Nov. 7, 1918. Shellac substitutes for use in making polishes and insulating materials are produced from natural resin, water resin, or colophony by isolating therefrom the amorphous constituents consisting of oxidized resin acids. Preferably the cryst. resin acids are first extd. by a solvent such as ether, benzene, oil of turpentine, or mineral oils, and the residue is then extd. with EtOH or MeOH giving a soln. corresponding with a soln. of shellac. This soln. may be used as a polish, or a solid shellac substitute may be recovered therefrom by evapn., and subsequently purified by sapon. with alkali and pptn. with acid. The product may be converted into metal salts or esters by treating with metal oxides, glycerol, and the like. To increase the proportion of shellac substitute recoverable, the raw material may be first oxidized under moderate heat by means of air, O, or ozone.

## 27. FATS, FATTY OILS AND SOAPS.

R. SCHERUBEL.

**Elm-seed oil.** HANS KREIS. Basel. *Schweis. Apoth. Ztg.* 56, 483(1918).—Preliminary note. The av. wt. of the winged seed was 7 mg.; without wing 5.5 mg. Only traces of starch were present. The seed, wings removed, contained H<sub>2</sub>O 9.3, ash 5.09, crude fiber 5.95, N substance 34.35, fat 28.22, N-free ext. 17.09%. The seed are excellent as chicken feed. The oil extd. with Et<sub>2</sub>O is greenish, odorless and tasteless and solidifies incompletely at 0°. When shaken with 75% H<sub>2</sub>SO<sub>4</sub> it turns a permanent olive-green, with HCl (d. 1.19) light green. No striking test is obtained with HNO<sub>3</sub>, and Bellier's test is indistinct. A mixt. of concd. H<sub>2</sub>SO<sub>4</sub> and concd. HNO<sub>3</sub> produces a passing green then a permanent coffee-brown color. Solstien's reagent at 40–50° produces a transient red. The consts. of the oil are d. 0.9374, acid no. 15.9, refraction no. at 40° 36.0, sapon. no. 274.1, I no. 31.8, Reichert-Meissl no. 3.0, Polenske no. 33.5. The high content of volatile fatty acids with low olein content is notable. When distn. was continued with renewal of H<sub>2</sub>O until 500 cc. were obtained, the Reichert-Meissl no. rose to 7.3, the Polenske no. to 121.5. Hence the volatile fatty acids are mainly insol. in H<sub>2</sub>O. The seeds also seem to be rich in lipolytic enzymes, since the acid no. increases to 160.5 when the crushed seeds are allowed to stand with H<sub>2</sub>O for 24 hrs. at an elevated temp.

S. WALDBOTT.

**Determination of unsaponifiable matter in fats and oils.** LEO MEYER. *Mitt. Lebensm. Hyg.* 9, 283-4(1918).—Comparison of results obtained on oils and fats and mixts. containing paraffin oil showed that the detn. of unsaponifiable matter by 2 sapons. was very little lower than that by 1 sapon. H. E. WOODWARD.

**Utilization of glycerol residues from Reichert-Wollny (Leffman-Beam) estimations.** A. E. PARKES. *Analyst* 43, 408-9(1918).—The cold residue from the detn. is filtered into a stock bottle. Sufficient solid  $\text{Ca}(\text{OH})_2$  is added to combine with total  $\text{SO}_4$  and the mixt. is boiled and filtered after intermittent shaking for a few hrs. The filtrate (dil. glycerol, NaOH and traces  $\text{CaSO}_4$ ) is concd. to  $1/2$  vol. when it will be approx. the required NaOH strength. Results with recovered glycerol were identical with fresh but the blank was somewhat higher due to sol. fatty acids in the original residue.

H. A. LEPPER.

**The manufacture of glycerol.** GEORGES VIR'. *Rev. prod. chim.* 21, 355-6(1918).—Description of well known processes. E. SCHERUBEL.

**The hydrolysis of soap solutions, measured by the rate of catalysis of nitrosotriacetnamine.** JAMES WILLIAM MCBAIN AND THOMAS ROBERT BOLAM. Bristol Univ. *J. Chem. Soc.* 113, 825-32(1918).—As a method of study the rate was investi-

gated of the catalysis of the reaction  $\text{CO} \begin{array}{c} \text{CH}_3.\text{CMe}_2 \\ \text{CH}_3.\text{CMe}_2 \end{array} \text{N.NO} \longrightarrow \text{H}_2\text{O} + \text{N}_2 +$

This reaction is unimolecular and its velocity is proportional to the concn. of OH ion. The volumetric method was used and was found to be accurate to within about 2 or 3% at ordinary temp. The results obtained show that the alkalinity of all soap solns. is low and cannot account for more than a few % of the cond. of soaps, except in very dil. solns. The alkalinity of soap solns. decreases with falling temp., but is increased again when the soln. solidifies or becomes heterogeneous. The concn. of the OH-ion in soap solns. is only of the order of magnitude of 0.001 N. This, however, is quite sufficient to exclude the existence of free fatty acids in soap solns. except in very minute amt. MAX PHILLIPS.

Soft soaps (WOODROFFE) 29. Cleaning and dyeing with volatile solvents (HEY) 25.

CHALMERS, T. W.: *The Production and Treatment of Vegetable Oils.* London: Constable & Co., Ltd. 218. net. For review see *Chem. Trade J.* 64, 97(1919).

FRYER, PERCIVAL J. AND WESTON, FRANK E.: *Technical Handbook of Oils, Fats and Waxes.* Vol. II. Cambridge: The University Press. 158. net. For review see *Chem. Trade J.* 64, 97(1919); cf. C. A. 12, 436.

MAXTED, E. B.: *Catalytic Hydrogenation and Reduction.* London: J. & A. Churchill. 48. 6d. net. For review see *Chem. Trade J.* 64, 97(1919).

**Purifying fatty oils.** SUPERIOR OIL & PROCESS CO. and W. P. SCHUCK. *Brit.* 120,820, Dec. 31, 1917. Fatty oils are purified by passing a current of H through them in the absence of catalysts at temps. not below  $185^\circ$ . The oils are thus deodorized, their free fatty-acid content is reduced, their I numbers are lowered, and they are rendered resistant to the development of rancidity. Castor oil is treated at  $185^\circ$ , eel oil and codliver oil at  $300^\circ$ , and corn oil at  $250^\circ$ , the operation being effected in 1-2 hrs. A suitable app. is specified.

## 28. SUGAR, STARCH AND GUMS.

A. HUGH BRYAN.

Report of committee on sugar manufacture and utilization of by-products, Hawaiian Sugar Planters' Association, 1918. HORACE JOHNSON. *Louisiana Planter* 61, 395-8, 411-3 (1918).—Cane shredders have given great satisfaction. By their use the extn. has been raised to 97.1% of the sucrose in the cane, and the capacity of the mill has also been increased. The use of shredders may make it possible to replace milling by diffusion. Expts. on centrifugal clarification have given no definite results as yet. Tests with the Oliver continuous filter have also failed so far to give results. Revolving screens employed to strain clarified juices or sirups have been found satisfactory. The most favored type of multiple effect is the quadruple, with pre-evaporator, the vapor from which is utilized for heating raw juices. The boiling capacity of the factories has been increased, and this, in conjunction with better management of the pans, has resulted in an improvement of the sugars. A table is given showing the compn. and size of grain of sugars turned out by the different plantations. 21 mills out of 40, representing 60% of the total output of the islands, have made satisfactory sugar, against 14 out of 42 in 1917, and 4 out of 31 in 1916. This is a better performance than in Cuba, but still further improvement is needed. The total recovery in 1918 was 2.23% higher than the av. of 1909 to 1914, and the extn. 3.24%, which shows that increased extn. is followed by increased recovery, amounting to 14,500 tons of sugar for the islands. The total loss in manuf. amounts to 12% of the total sugar; 25% of this is lost at the mill, 1.75% in press cake, 58.25% in molasses, and 15% is undetd. The molasses is exhausted to an av. of 40 gravity purity. Lab. tests have shown that it is possible to reduce the purity to from 28.14 to 31.67, but it remains to be detd. how low a figure can be reached in actual practice. Undetd. losses, caused by fermentation, may be reduced by cleanliness and use of formalin. Expts. in Java have shown that as much as 6% of the total sugar may be lost by the activity of microorganisms at the mill, and for this reason extreme cleanliness is imperative at that station. Losses by entrainment can also be reduced by proper manipulation and cleanliness. Further studies should be made towards obtaining still higher extn., a better recovery from low-grade massecuites, and improvements in methods of clarification. One new method of clarification, advocated by Peck and Adams, consists in filtering the clarified juice through decolorizing carbon made from a mixt. of final molasses and kieselguhr with concd.  $H_2SO_4$ . In lab. tests increases in purity of 4.4 to 1.5 points were obtained, and removal of 95% of coloring matter, decreasing with repeated use to 70%. A large decrease in gums and ash was effected. Almost as good results were obtained in a small-scale expt. with a filter press. The C is again freed from the impurities taken up by washing with hot water and steaming. The C-treated juices were boiled to sirup and to grain much more rapidly than ordinary clarified juices. Later a still larger expt. was made with satisfactory results, in spite of adverse conditions. The juice was readily concd. with no scale formation. The ash of the C, 30% at the beginning, increased after repeated use to 60%. *Utilization of by-products: Bagasse as fuel* is worth as much per ton as oil per barrel. Bagasse will shortly be utilized in Hawaii for the manuf. of an *asphalt roofing paper*, employed in cane cultivation, and of other paper products. The bagasse is sifted to remove pith, treated with steam and lime, sent through the beaters, oven drying screens, further dried in mills, and pressed. It is then satd. with 40% asphaltum. The cost of manuf. is \$30 per ton. *Press cake* is used exclusively as *fertilizer*. Various sugar men in the islands place the value of press cake at \$5 to \$20 per ton, with an av. of \$10. The actual value will have to be detd. by field tests. *Molasses*: Sixty % of the total output is sold, 7% fed to stock, 15% used as fuel, 10%

for manuf. of potash, and 8% thrown away. As fuel, molasses is worth the same as bagasse; when burned for potash, \$15 per ton, at \$5 per unit of potash. The actual selling price is \$7 per ton. A new outlet for waste molasses may be the conversion into denatured alc. as a gasoline substitute. The denaturing formula, approved by the Internal Revenue officials, is 100 gals. alc., 25 gals. ether, 2 gals. benzine, 1 gal. pyridine. The distillery slops will still contain all of the fertilizing constituents of the molasses, and they alone will more than pay for the molasses. F. ZERBAN.

Some notes on present conditions in Louisiana sugar houses. C. E. COATES. *Louisiana Planter* 61, 393-4, 410-1(1918).—There is at present a tendency, to be encouraged, towards the manuf. in Louisiana of sugars, sirups and molasses for direct consumption, without refining, processing or blending. All these products must be carefully standardized. High-grade sugars should invariably be passed through granulators; first molasses should be of about 50 to 53 purity, second molasses of 37 to 40 purity, and both of them of about 78° Brix. More attention ought to be paid to flavor than to color. A number of improvements are pointed out, which will favorably affect quantity, quality, and cost of the products. The principal ones are deep grooving of the mills; increased extn. by the use of crushers, shredders, and larger number of rolls, up to nine; filtration of the entire juice by the use of bag filters and presses, and possibly that of the newer types of filters, like the Kelly and Sweetland press, and centrifugal filters; a greater effort in keeping the effects clean, not only the lower part, but the entire body and dome, to prevent contamination with iron which imparts a dark color to the sirup; the exptl. use of one of the new acid- and alkali-proof paints in the effects; a more elastic way of connecting the different bodies of the effect, so that one or more of them may be disconnected and cleaned while the others are being used; boiling of the sirup to high density, in order to shorten the boiling in the pan which will save fuel and give a sugar of better color; the more general introduction of calandria pans, with two coils if necessary; double purging of the sugar; use of more crystallizers, provided with seeding devices; greater attention to the fuel-saving problem; washing and accurately weighing all the cane entering the mill; more extended chem. control, and, if possible, mutual control. An excellent sirup has been made in an exptl. plant by Dale. Neither lime nor S was used. The juice was mixed with kieselguhr, boiled and filtered. Invertase was added to the partly cooled juice, and the latter boiled to the desired d. A sirup of good flavor is obtained in this way. F. ZERBAN.

Experiments on methods for preventing the decomposition of frozen canes. W. E. CROSS. *Rev. ind. agr. Tucuman* 9, 51-6(1918).—Neither windrowing, nor topping of the standing cane, as practiced in Louisiana, showed any advantage over leaving the cane standing without any treatment, as was shown by field tests made after the heavy freeze of June 23, 1918. The topped cane, and more so the windrowed cane dried out considerably, and their purity decreased rapidly, while the standing cane kept fairly well. F. ZERBAN.

Report on milling in Hawaii. J. P. FOSTER. *Intern. Sugar J.* 21, 17-22(1919).—From the replies to a questionnaire concerning the economic limit of extn. the conclusion is drawn that the fuel expense is the only limiting factor, and that extn. should be pushed as high as possible. As high as 75 to 80% of the sucrose extd. can be recovered. F. ZERBAN.

Seedling sugar canes. J. B. HARRISON. *Intern. Sugar J.* 20, 558-60(1918).—Reprinted from *Agr. News*. It has been very difficult to produce seedling canes which will not soon show signs of degeneration when second and third ratoons are grown, while it is comparatively easy to breed varieties which will hold up well, if replanted every year or two. Up to 1902 breeding work in Demerara consisted mainly

in the selection of seedlings obtained by chance fertilization, the principal object being vegetative vigor and high sugar content. Controlled cross-fertilization has so far proved rather disappointing. The natural varieties represent very complex hybrids, and are therefore unsuitable for this particular purpose. It is to be expected that from strains of high purity valuable varieties may be derived by controlled cross-fertilization, but this procedure is naturally very slow. F. ZERBAN.

**The new American polariscope.** CHARLES E. COATES. *Louisiana Planter* 62, 58-9(1919).—Report of a committee appointed by the Louisiana Section of the A. C. S., to draw up specifications for a saccharimeter to be manufd. in the U. S. The principal features recommended are: The adoption of the "international" normal wt. of 20 g. per 100 true cc. at 20°; field of vision divided into halves, not into 3 parts; light filter to be placed between instrument and light source, and not within the instrument; single quartz wedge compensating system, ranging from +110 to -35. The Jellet-Cornu prism is recommended for instruments to be used in the tropics, but the choice between this system and the Lippich should be optional with the purchaser. There are some further minor suggestions regarding mechanical design. F. ZERBAN.

**The manufacture of polariscopes in the United States.** C. A. BROWNE. *Louisiana Planter* 62, 12-4(1919).—Tentative specifications for a polariscope have been submitted to sugar chemists in the U. S., Hawaii and Cuba, so that any instrument to be manufd. in the States may conform as much as possible to the wishes of prospective users. The advantages of the 20 g. normal wt. are again enumerated. Extracts are given of letters from a number of sugar chemists, most of whom favor the adoption of this normal wt. F. ZERBAN.

**Baumé or Béaumé?** C. A. BROWNE. *Louisiana Planter* 61, 363-4(1918).—There is considerable confusion among authors concerning the spelling of this name. The proper spelling is that used by the chemist in question himself, which is "Baumé." The use of the Baumé scale in the sugar industry should be abandoned, in favor of the Brix scale, because Baumé degrees must first be converted into Brix degrees, to have any definite meaning. F. ZERBAN.

**The Mauritius sugar industry.** H. A. TEMPANY. *Intern. Sugar J.* 20, 554-8 (1918).—Report of the Dept. of Agr. of Mauritius for 1917. Methods of manuf. are constantly improving, and good progress is being made in the fight against insect pests. Root disease is, however, becoming more prevalent. Labor-saving implements could be used to a larger extent. Chem. factory control is gaining ground. Fertilizers should be used more judiciously, on account of their high price. The cane area under irrigation is spreading from year to year. Close attention should be paid to the cost of production, to offset any decrease in sugar prices, and the partial loss of the Indian market. F. ZERBAN.

**The sugar industry in Mexico.** ANON. *Bull. chambre de commerce française du Mexique; Intern. Sugar J.* 20, 547-50(1918).—The production of sugar has steadily declined, from 160,000 tons in 1910-11 to 35,000 tons in 1917-18, on account of the political disturbances. There is no possibility of reviving the industry until uninterrupted peace is again established in the country. F. ZERBAN.

**France. The beet sugar campaign of 1917-18.** GEORGES DURBAU. *Intern. Sugar J.* 20, 540-2(1918).—This article contains mainly statistical data on the production of beets, sugar and molasses, and on prices of these products. Production of beets per acre, sugar content of the roots, and factory output were better than during the previous year. The proportion of first masseuite to second and third has steadily risen since the introduction of crystn. in movement and of boiling back methods. French factories compare well, in most respects, with those in other countries, but the cost of

manuf. could be further reduced by increasing the capacity of the factories, and by more economical fuel consumption.

F. ZERBAN.

Brazil. The sugar industry. ANON. *Board of Trade J.*; *Intern. Sugar J.* 20, 538-9(1918).

## 29. LEATHER AND GLUE.

---

ALLEN ROGERS.

Scudding, its uses and functions. J. R. BLOCKEY. *Shoe and Leather Rep.* 141, 143, Dec. 26, 1918; 79, 81, 90, Jan. 2, 1919.—Scudding is a process generally applied to hides and skins after liming and unhairing. It consists in passing the knife over the grain with a pressing motion. Scudding is also often performed after any of the various operations up to tanning. The changes brought about by liming enable one to remove by scudding not only the short hairs, the epidermis, and surface dirt and coloring, but also to squeeze out some of the liquefied fat and hide or cementing substances, and the lime soaps. The removal of these substances is, for certain purposes, important. Short hairs not removed will become firmly fastened in tanning and will seriously interfere with finish and dyeing, especially for black upper leather. Grease particularly, and also the coloring matters from the hair roots, if not removed, cause trouble in uniform dyeing. Tanning is actually prevented or retarded at times by grease. Scudding several times, as for example, after unhairing, fleshing and possibly liming, has been known to be very effective in tanning greasy hides. With heavy leathers scudding after acid deliming has certain advantages in that there is a saving of the hide substance due to the pptg. of the latter in the hide by the acid. One disadvantage is the danger of scudding-knife marks which may become fixed in the tanning. Suspension of the delimed, scudded hides overnight in H<sub>2</sub>O before tanning will overcome the danger of lasting knife marks. Light skins may be scudded several times and after any of the foretanning stages.

R. W. FREY.

Alum-tanned boot leather. F. T. HOWARD. *Leather World* 10, No. 46, 845-6; No. 50, 934-5(1918).—While pure alum-tanned leather is principally used to-day for belt laces, combing leathers, and sometimes for picker bands, it was at one time, after being further treated with egg yolk, flour, and oil, extensively used as calf kid for boots and shoes. As a matter of record, the manuf. of this leather is given. Soaking, liming, unhairing, fleshing, drenching, dressing with egg yolk, flour, and oil, tawing, drying, staking, dyeing, ironing, and finishing with soap, oil, and beeswax are described in detail. Also in *J. Am. Leather Chem. Assoc.* 14, 62-8(1919).

R. W. FREY.

Chrome-tanned Buffalo hide picker bands. E. H. HOWARD. *Leather Manufacturer* 30, No. 1, 11-4(1919).—This leather is used in the weaving districts throughout the world. It must be very soft and tough, but not too greasy, as the friction on the bands heats them and softens the grease, causing it at times to drip and soil the cloth being woven. So-called "raw hide" bands, while extensively used, are not so favorably

considered as is chrome leather, probably because of the comparatively greater detrimental effect of the heat upon the former class of stock. English or salted ox hides are the very best ones to use but generally dried buffalo hides imported from East India, China, and the Dutch Colonies are utilized. Because of poor curing and handling, many of the hides are defective when received but may not be noticed until soaked so that as a general thing the manufacturer of picker bands from buffalo hides would do well to buy his raw goods already limed, fleshed and trimmed with bellies and shoulders off. This can be done from the firms who buy buffalo hides and sort them after fleshing for their clients. When starting with dry hides they should be selected for weight before soaking. After soaking, milling, liming, and fleshing the sound goods of the lighter class are selected for picker bands. As little splitting as possible should be done in order not to sacrifice any toughness. Bating is generally done with hen or pigeon manure, although several of the patent bates are satisfactory. Lactic and formic acid may also be used. From the bate a very soft, silky hide should be obtained. Pickling with  $H_2SO_4$  and NaCl or better yet alum and NaCl follows: Both the one- and two-bath processes of Cr tanning are used and are described; the latter is recommended. The goods are then neutralized with 2%  $Na_2B_4O_7$  and fat-liquored with soap and castor or neatsfoot oil. Stuffing follows, and such a mixture should be selected that the subsequent working temp. for the band will not cause the grease to soften and fly off. A mixt. of 30 lbs. of hard stearin, 30 lbs. of paraffin wax, 20 lbs. of tallow and 20 lbs. of oil is suggested, but the quantities should be varied some what to suit the requirements of any particular weaver. The leather is set out well and dried. Piling in a cool place for about 3 weeks makes it more mellow and pliable. French chalk is then rubbed in on both grain and flesh and the leather is cut into bands, which process is briefly described.

R. W. FREY.

**Absorption of tannic acid in sole-leather manufacture.** ALLEN ROGERS. *J. Am. Leather Chem. Assoc.* 13, 520-7(1918).—Analyses are given of leather samples on wet and dry basis taken beginning with the raw hide and at frequent stages in the rockers, layers, etc., tempering pit, bleach, oil wheel, loft and after rolling. Analyses of liquors from tail rocker to head third layer are given, and other liquor analyses to show the effect of taking samples at top, middle and bottom of the pits. The results indicate that over half of the tannage is accomplished during 15 days in the rockers and that after 13 days in the press layers tannage had reached  $\frac{4}{5}$  of the total absorption. The cost per hide, on a basis of 7 cents per tan unit, of putting stock through the yard is \$1.264 in rockers, \$0.3175 in press layers, \$0.1125 in first layer, \$0.2600 in second layer, \$0.0264 in third layer, or a total of \$1.9804. Analyses of samples of liquors taken from the top, middle and bottom of pits show higher tannin in the middle and bottom portions; a point which should be considered in taking an inventory. Analyses are also given of the sludge from the ext. house and rocker pit. It is concluded that a sample analysis of yard liquors is not sufficient basis for calcg. the complete cost system; that the degree of tannage is not subject to a mathematical calculation; and that the yard should never be considered as half-tanned.

J. S. ROGERS.

**Shark-skin leather.** ALLEN ROGERS. *J. Am. Leather Chem. Assoc.* 13, 528-30 (1918).—After numerous expts. in the tanning of shark skins the following procedure was found to give the best results: Upon arrival the skins are cut into sides, soaked 24 hrs., washed thoroughly, placed in paddle in a 0.2% NaOH soln., stirred occasionally for 2 days, washed, and fleshed by machine or by hand. The grain which was still harsh was beamed with a blunt knife to remove shagreen. The difficulty in removing the outer layer which appears much like rough sandpaper was partially overcome by the NaOH treatment. The fleshed beamed stock was bated with  $NH_4Cl$  at 100° F., using 3% of the wt. of the stock, and washed. The stock was tanned as follows:

The skins were drummed until struck through in a soln. containing 5%  $\text{Na}_2\text{Cr}_2\text{O}_7$  and 2.5%  $\text{H}_2\text{SO}_4$  in 5 gals. water to each 100 lbs. of stock, horsed overnight, then drummed with 6 lbs.  $\text{NaHSO}_3$  in 4 gals. water to each 100 lbs. of stock until the chrome was entirely reduced, then horsed overnight. From this stage the skins can be finished as regular chrome stock; but better results are obtained by retanning in quebracho, running for 1 hr. in a 10° Bk. quebracho liquor, then until struck through in a 30° Bk. liquor, and finally 5 days in a 40° Bk. quebracho layer. The skins are then fat-liquored or stuffed according to the grade of leather desired.

J. S. ROGERS.

**The non-tannin enigma.** JOHN A. WILSON AND ERVIN J. KERN. *J. Am. Leather Chem. Assoc.* 13, 429-38(1918).—This work was inspired by a letter from Alsop giving results of expts. which he had carried out on the detn. of non-tans of a chestnut ext. under different conditions of concn. of soln. and amt. of hide powder, and also by the results obtained by the Committee on the Effect of Hard Water on Tannins (*C. A.* 13, 84). Results of expts. on shaking pure solns. of salts and other non-tanning materials with chromed hide powder are tabulated and indicated graphically. These results were calcd. approx. before the expts. were performed by application of formulas published by Procter and his collaborators from time to time on the theory of the equil. of colloid jellies and electrolytes. Solns. of gallic acid, cane sugar,  $\text{NaCl}$ ,  $\text{H}_2\text{SO}_4$ , and  $\text{MgSO}_4$  were used. The non-tannins are divided into the following types: electrolytes which do not combine with hide powder; non-electrolytes which do not combine with hide powder and substances which do combine with hide powder. The influence of the presence of each type of non-tannins on the analytical results is discussed fully. The results show that the addition to a tan liquor of any sol. substance having no action on the hide powder will tend to raise the % of non-tannins to a figure higher than its true value while the addition of any sol. non-tanning substance which combines to a very appreciable extent with the hide powder will tend to decrease the non-tannin figure. The error in either case is increased by using large proportions of hide powder and is decreased by using more concd. liquors. In Alsop's expts. decreasing the concn. from official to  $\frac{1}{4}$  strength only lowered the non-tannins from 18.76 to 18.30 while decreasing the amt. of hide powder from 50 to 12.5 g. raised the % of non-tannins from 18.30 to 22.07. It is in closing that in a liquor of definite tannin content an alteration of the nature or concn. of non-tannins will cause a corresponding change in the % of tannin obtained by the official method, even though there actually is no alteration on the tannin content nor emphasized in the amt. of tannin removed from soln. by the hide powder. It is therefore not permissible in investigational work to compare the tannin figures of liquors containing different kinds or amts. of non-tannins without taking this into consideration."

R. W. FREY.

**The "forsare" liming process.** ANON. *Leather Trades Review* 822-3, Dec. 11, 1918.—A description is given of a liming process in use at the Messrs. William Walker and Sons, Ltd., Bolton plant, which was referred to by Mr. C. E. Parker in a recent lecture as the "Walker-Bolton" method. The essential features are constant agitation of the liquors by compressed air from tubes across the bottom of the pits and removal of these liquors by air lifts. The suspended hides are soaked and limed in the same pit without being removed until ready for unhairing, thereby saving much labor. Because of the constant agitation, soaking and liming are very uniform, efficient, and rapid. Liming is completed in from 3 to 4 days, the hides are thoroughly plumped and do not suffer the loss of much hide substance. Only about 3 lbs. of lime per hide are required instead of from 8 to 10 by the old processes. In order to make the liming less subject to seasonal variations in temp., the compressed air is heated to the av.

summer temp. Air pressure from 12 to 15 lbs. above atm. pressure is ample and the compressor for 1000 hides per week capacity requires at the max. 15 h. p.

R. W. FREY.

**Methods of bating and drenching.** ANON. *Leather Manufacturer* 30, No. 1, 7-8(1918).—New England tanners call killing the lime "drenching," while the same process is called "bating" by Pennsylvania and Delaware tanners. Bating is usually done in the paddle and should never be done in stationary tubs. Overbating will give loose-grained and spongy leather, while underbated skins still contain lime and will produce hard, brittle, and cracky leather, which in fancy dyeing will give uneven color. Excrement bates, besides their disagreeable features, vary in strength and action. Their control requires skilled tanners, and even then the result is uncertain. These bates consume much of the gelatin of the skin which is the life of the fiber and besides makes for fineness of texture and toughness of the leather.  $H_2BO_3$  gives excellent results as a bate, and when used with a bacterial bate is one of the best lime cleansers known. For drenching or bating light skins bran is mostly used. An emulsion of bran, middlings, or flour is allowed to ferment until quite acid before immersing in it the hides and skins. The bran drench is a long and likewise dirty, uncertain operation. It is often claimed that the acid-forming ferments saturate the skins and are carried over to the tanning liquors where they cause further acid fermentation. Weeds containing tannin are sometimes present in the bran and may cause spotted and cloudy tanned stock. Some of the patent bates give gratifying results. For proper bating more than killing the lime is necessary. The skins must be reduced to a certain extent by some bacterial action, after which a bath in  $H_2BO_3$  will remove all remaining lime.

R. W. FREY.

**Niter cake as a substitute for sulfuric acid.** J. B. CHURCHILL. *Shoe and Leather Rep.* Oct. 24, 1918; *J. Am. Leather Chem. Assoc.* 13, 607.—A report to the Tanners Council. Data on the production of niter cake in the U. S. show an almost unlimited quantity produced in widely scattered sections of the country. Analyses of many samples show 26-40% acid as  $H_2SO_4$ . The selling price f. o. b. shipping point, varies from \$2 to \$9 per ton. Reports from tanners indicate that niter cake has been successfully used in bleaching sole leather, for deliming previous to Cr tanning, for pickling, and in making up one-bath Cr liquors. The large amt. of  $Na_2SO_4$  in niter cake should be allowed for in making up mixtures which should contain  $H_2SO_4$  and salt.

R. W. FREY.

**Cu-Nao. Its utilization in tanning.** JALADE. *Bull. sci. pharmacol.* 25, Pt. 2, 298-301(1918).—The so-called "dry extract" of this common plant (*Dioscorea atropurpurea* Roseb.) of Indo-China consists of dried slices of the tubers and is not, properly speaking, an ext. 100 parts contain 16.43  $H_2O$ , 20.20 tannins absorbed by hide powder, 7.07 sol. nontannins, 26.8 starch, 3.24 N-contg. derivs. (Kjeldahl), 0.32 fat, 25.94 cellulose. The tannins were detd. in the soln. obtained by exhausting with  $H_2O$  at 50°, the use of higher temps. being inadvisable owing to the large amt. of starch present. The tannins belong to the pyrocatechol group and give a grayish ppt. with ferric salts. A reddish yellow coloring matter is also present. Ash 2.10%, strongly alk. in  $H_2O$ , contains  $SiO_2$  and  $CO_2$ , with traces of Al, Fe, Ca and Mg tests for K were negative. After extn. of the tannin the residue might be used as a feed, but the difficulty of drying and the rapid development of molds are obstacles.

M. HEIDELBERGER.

**Notes on soft soaps.** D. WOODROFFE. *Leather Trades Rev.* 1918, 820, Dec. 11.—Attention is called to the inferiority of soaps during the War. Many of the so-called soft soaps on the market do not appear either to be potash soaps or to contain any glycerol, which is misleading since English and Continental technologists describe

soft soaps as potash soaps containing glycerol. Analyses of samples of com. soft soaps are given and show that most of them do not contain any glycerol. By the modern methods of soap-making the oils and fats are first hydrolyzed, thus permitting a sepn. of the glycerol from the fatty acids, which are then mixed with the necessary amt. of alkali to furnish soap. Most of the soft soaps are merely ordinary soda soap with a higher  $H_2O$  content. While the value of glycerol in leather dressing is a much disputed point, W. still is of the opinion that the glycerol content of soft soaps is an important factor in their use for fat liquoring. The glycerol in the soft soap makes the emulsion more stable and the globules of oil more finely divided. In view of the difficulty of purchasing genuine soft soaps it is recommended that the leather dresser prepare his own. Not only is this easily done but the best and most suitable oils can be used.

R. W. FREY.

**Leather compositions.** H. E. WHITE. Brit. 120,802, Dec. 7, 1917. Leather waste or scrap is first treated with weak acid soln., *e. g.*, 10% strength HCl, or with acid and salts such as  $MgSO_4$  or NaCl. The excess of acid may be removed and the waste heated to, say,  $100^\circ$ , with or without stirring or crushing or otherwise working to produce a homogeneous mass, which may be rolled, pressed, extruded, etc., or, after treating with acid, the waste may be heated alone, or with methylated spirit, olive or other oil, or gelatin, until it becomes homogeneous and may be worked. The product is then hardened by HCHO, Cr compds., tanning exts. or compns. (including those prepd. synthetically), or by picric acid alone or in combination with oils. During the treatment, organic or inorganic filling materials may be added.

**Tanning.** K. BENDIXEN. Brit. 120,398, Oct. 26, 1918. Fishskins, etc., are treated prior to tanning to ext. the oil and fatty matters either wholly or partially. The extn. is effected by treating the skin with any fat-removing means, *e. g.*, a lye consisting of a soln. of  $Na_2CO_3$ , etc., and the excess of lye is neutralized by an acid, such as weak HCl. The skin is washed either after the treatment with lye or after the addition of acid.

**Tanning.** L. R. PAYRACHE and O. V. BAILLY. Brit. 120,928, Nov. 22, 1918. A bate for the treatment of hides consists of an opotherapeutic pancreatic powder, prepd. from fresh pancreatic glands and contg., in addition to the water-sol. principles of said glands, the whole of their sol. and insol. enzymes. One method of prepg. the powder consists in finely triturating fresh pancreas and mixing the pulp with acetone, filtering, and pressing the residue. This residue is subjected to two further treatments with anhydrous acetone, and, when dry, is powdered. The powder is dissolved in  $H_2O$  at  $30-40^\circ$ , either alone or after mixing with a similar powder obtained in a like manner from fresh mucus of the small intestines, and may be mixed with neutral or faintly alk. or acid unliming agents, with the addition of inert substances such as cellulose, or its derivs., etc.

**Glue.** R. W. MUMFORD. U. S. 1,289,053, Dec. 24. Clear and decolorized glue or similar product is produced by mixing the gelatinous material, in soln., with decolorizing C, and also with a small amt. of kieselguhr, agitating the mixt. vigorously, sepg. the decolorizing material, and then cong. the soln.

### 30. RUBBER AND ALLIED SUBSTANCES.

JOHN B. TUTTLE.

Technical course in rubber manufacture. H. E. SIMMONS. *Rubber Age* 3, 118-20, 169-71, 210-12, 249-51, 294-6(1918).—Section XXII: Analysis of Manufactured

Rubber. Section XXIII: Physical testing of compounded samples. Cf. C. A. 12, 103, 342, 871.

JOHN B. TUTTLE.

Rubber substitutes, or vulcanized oils. ANDRÉ DUBOSC. *Chimie et industrie* 1, 727-32(1918).—A description of the methods used in the manuf. of white and brown rubber substitutes. It contains nothing new.

JOHN B. TUTTLE.

Accelerene: a catalyst in rubber vulcanization. ANON. *Caoutchouc et gutta-percha* 15, 9464-6(1918).—A popular description of the use of this accelerator ( $p\text{-NO-C}_6\text{H}_4\text{NMe}_2$ ). For soft cured goods 0.5% is recommended, and 0.75% for ebonite. It is claimed that the finished product possesses greater durability than it would have when other catalysts are used.

JOHN B. TUTTLE.

Polymerization and oxidation of crude rubber. A. DUBOSC. *Caoutchouc et gutta-percha* 15, 9478-82(1918).—A review of work done at Delft under Van Rossem (cf. C. A. 12, 2463).

JOHN B. TUTTLE.

The chemistry of vulcanization. D. F. TWISS. *Caoutchouc et gutta-percha* 15, 9484(1918).—A review, containing no new matter.

JOHN B. TUTTLE.

Aging of plantation rubber. II. HENRY P. STEVENS. *J. Soc. Chem. Ind.* 37, 340-21(1918).—A continuation of his work on a study of the aging properties of vulcanized rubber (cf. C. A. 13, 387). This series deals with smoked sheet, smoked slab, pale crepe and smoked crepe. The results of the previous expts. on ordinary sheets and slab rubber were confirmed, samples having the highest coeff. of vulcanization showing the most rapid deterioration. The max. tensile strength is secured only by overcuring, and such samples age quickly. There was practically no difference in behavior between the various kinds of rubber.

JOHN B. TUTTLE.

Rubber-producing weeds in Germany. H. E. PEARSON. *India Rubber World* 59, 201-2(1919).—A discussion of some rubber-bearing plants found in Germany including *Abrotylis gummifera* L., *Sonchus oleraceus* L., *Euphorbia cyparassias*, and others.

JOHN B. TUTTLE.

Specifications for pneumatic tires and tubes, adopted by the Motor Transport Corps (U. S. Army). ANON. *India Rubber World* 59, 16-22(1918).—Specification Nos. 1046, 1062, 1065, 1066, 1067, 1068, 1069, 1070, 1071 and 1072 for pneumatic tires and tubes.

JOHN B. TUTTLE.

Rubber laboratory organization. H. B. UNDERWOOD. *India Rubber World* 58, 534(1918).—U. suggests the following organization for a lab. connected with a rubber factory: (1) Testing of raw materials: *a*, rubber; *b*, fabric; *c*, compounding ingredients; (2) factory control; (3) development: *a*, new compds.; *b*, research; *c*, manufacturing processes; (4) commercial, *i. e.*, a study of competitors output.

JOHN B. TUTTLE.

Jar rings for cold-pack preserving. ANON. *India Rubber World* 58, 584(1918).—Specifications adopted by the U. S. Dept. of Agric., States Relations Service, Office of Extension Work North and West, for rubber jar rings. Methods for testing are given.

JOHN B. TUTTLE.

The absorption of water by vulcanized fiber and erinoid on exposure to moist air and the consequent change of electrical resistance. R. G. ALLEN. *Sci. Proc. Roy. Dublin Soc.* 15, 405-14(1918); cf. C. A. 12, 2497.—Plates of vulcanized fiber, red and blue erinoid,  $5.5 \times 5.95 \times 0.5$  cm. were exposed to air of satd. humidity for 400 hrs., when the fiber had absorbed 3.42 g., the red erinoid 1.43 g., and the blue erinoid 1.26 g. Comparable results were obtained with samples in the form of tubes. Tables are given showing the elec. resistance of the samples, and the effect of increased absorption of water at various temps.

JOHN B. TUTTLE.

**Colored rubber.** INDIA RUBBER CO. Brit. 120,824, Jan. 2, 1918. A sheet of rubber or rubber fabric is provided with pigment (*e. g.*, Al powder) in its outer layer only, the pigment being imbedded by vulcanization so as to produce a smooth, glossy surface. Thus, a sheet of vulcanizable rubber mixing may be sprinkled with a dry, powdered pigment without incorporation, and metal foil or other confining surface placed over the pigment preparatory to vulcanization. The rubber and foil may be superposed in a succession of layers, *e. g.*, by reeling into a compact roll, to facilitate handling. The product may be employed as a balloon or like fabric or as a wing, boat, or pontoon material for airplanes.

**Rubber compositions.** W. STROCKS. Brit. 121,136, Nov. 29, 1918. A mixt. of pure rubber, flour from waste vulcanized rubber, and S, with or without other ingredients, is used in making artificial leather, floorcloth, tires, etc. The mixt. of rubbers and S is calendered into sheets which are used as stock, which may be mixed with other materials such as pontianak, a clear, sticky gum, castor oil, ground fiber, white Pb, and dissolved resin. The products are vulcanized by a cold or hot process. Thin sheets of the material may be superimposed with the grain produced by rolling arranged alternately at right angles, and then compacted by pressure.

**Halogenating rubber.** S. J. PEACHEY. Brit. 121,091, Dec. 11, 1917. Alkyl, alkylene, alkenyl, and aryl halides, such as trichloroethylene and tetrachloroethane, are used as solvents in the making of halogenated rubber, gutta-percha, or balata according to the process described in 1,894, 1915 (*C. A.* 10, 1950), *i. e.*, treatment with Cl gas of rubber, dissolved in a solvent which does not react with Cl; also according to the process described in 121,194, in which  $\text{SO}_2\text{Cl}_2$  or a mixt. of Cl and Br or Br followed by Cl is used for the halogenation of rubber, gutta-percha, or balata.

**Plastic oxidation product of rubber.** W. O. SNELLING. U. S. 1,288,723, Dec. 24. A plastic material suitable for use in the manuf. of *chewing gum* is obtained by exposing thin sheets of Pontianak rubber, while moist, to the action of  $\text{O}_3$  for a few min. and then to the action of air for such time as required to impart the desired degree of plasticity. This treatment imparts to the materials a somewhat unpleasant taste, which is removed by washing successively with very dil. NaOH soln. and  $\text{H}_2\text{O}$ . A similar action on the rubber is effected by the use of alk. earth peroxides and HCl to generate  $\text{H}_2\text{O}_2$  in contact with the rubber.  $\text{BaO}_2$  may be used merely to initiate the action if desired, followed by treatment with  $\text{O}_3$ . Very weak  $\text{HNO}_3$  or nitrous fumes also may be used. The general properties of the product very closely resemble chicle. It may be mixed with turpentine to form a cement-waterproofing compn. The oxidation may be hastened by the use of catalysts such as oleic acid, salts of Cu and Fe (*e. g.*, Cu oleate), palm oil, Cu resinate or Mn resinate, which may be added to the amount of 0.5-1% of the wt. of the rubber. Cl effects an action on the rubber similar to that of  $\text{O}_3$ .

## 1. APPARATUS.

L. C. JONES.

Laboratory apparatus for rapid evaporation. E. C. MERRILL AND CLARE OLIN EWING. *J. Ind. Eng. Chem.* 11, 230(1919); illus.—The app. has been found to be especially useful with solns. which are prone to decrepitate and for the drying of wool fibers used in *qual. color analysis*. By proper adjustment rapid evapn. at low temp. can be made. E. J. C.

Substitutes for platinum in electrolytic apparatus. PAUL NICOLARDOT AND JEAN BOUDET. *Bull. soc. chim.* 23, 387-91(1918).—Tests were made to det. the suitability for use as electrodes of alloys of Au and Pt containing from 12.5 to 25% of Pt. It was found that as cathodes they stood up very well, but as anodes they failed because of their loss in wt. during electrolysis in alk. solns. or in presence of sulfides and NaCN. The authors recommend for the cathode an alloy composed of Au, Ag and Cu in the proportions 920-50-30, and resistant to HNO<sub>3</sub>, H<sub>2</sub>S and O<sub>2</sub>, and for the anode the same alloy further protected from anodic oxidation by being electrolytically coated with a thin layer of Pt (0.005 g. per sq. cm.). J. L. WILEY.

An improved automatic buret. GEO. J. HOUGH. *J. Ind. Eng. Chem.* 11, 229 (1919); illus. E. J. C.

Limit of sensitiveness in the string galvanometer. I. K. A. WERTHEIM SALOMONSON. *Proc. Acad. Sci. Amsterdam* 21, 235-42(1918).—A discussion of the factors detg. the sensitiveness of an Einthoven string galvanometer. Al is the best material for measurement of small potential differences; a string 1  $\mu$  diam., 6.65 cm. long, completely relaxed, will give a deflection of 276 mm. for one microvolt, if the field strength be 997 gauss, and if the magnification be 1000 times. In a perfect vacuum the string would be critically damped. GEORGE W. MOREY.

Non-silverable containers for silvering mirrors. W. W. COBLENTZ. *Science* 49, 192-3(1919).—A further discussion. Cf. *C. A.* 12, 2263. E. H.

Some useful testing machines. H. S. PRIMROSE AND J. S. GLEN PRIMROSE. *Engineering* 106, 354-6, 385-8(1918).—The combined *tensile, crushing, and transverse bending machine* is operated by hydraulic pressure. Two fixed heads are mounted one above the other and a cradle is moved up and down between them by a yoke connected to a hydraulic plunger. A sep. device, connected into the pressure line between the pump and the plunger, measures the force by the displacement of a pendulum so that a pointer on a gage dial continuously indicates the force. Autographic records of the loading are also obtained from the pendulum. For standardizing, a thin-walled steel box filled with Hg is used. It carries a glass tube with a calibration mark, and a plunger actuated by a small micrometer screw. The Hg is adjusted to the mark in the glass tube, the load (either tension or compression) is applied, and the vol. change read off the micrometer after re-adjusting the Hg to the zero. A *torsion machine* is described in which the deforming couple is balanced by the displacement of a heavy pendulum. Here also the load is read and the autographic records are drawn from the

Acc. 2106

pendulum displacement. Since this arrangement does not necessitate a rigid stationary head, the stationary head is arranged so that it is free to move along the axis of the machine. As the test piece shortens under torsion the stationary head moves and thus no tensile load is applied. The *Brinnell test* may be made in the compression machine described above. A loose collar rests on the test piece, and the motion past this collar of the plunger carrying the ball actuates a needle, so that the depth of the impression may be read directly from a dial. A similar arrangement is described for the Ludwik cone instead of the Brinnell ball. The above, together with a swinging hammer impact machine of no unusual features, are made by Amsler. A *Brinnell machine* is described in which the test piece rests on an anvil supported by a spring. The ball is run down into contact with the specimen by a screw with a friction nut which slips when contact is made. By moving a lever the spring under the anvil is compressed, forcing the specimen against the ball with a definite, known force. On releasing the pressure the ball is again run down into contact with the piece and the depth of the impression read off from graduations on the friction nut. Two forms of this machine are described—a small portable machine with a vertical yoke, and a larger horizontal machine with an opening large enough for 12-inch specimens. An *impact testing machine* consists of a heavy flywheel carrying the hammer in such a way that it can be brought into contact with the specimen when desired. The energy absorbed in breaking the specimen is detd. from tachometer readings before and after impact. These latter machines are designed by Guillery and made by Malicet and Blin, Aubervilliers, France. All the machines described have been used in British munitions plants. W. L. BADGER.

A practical oil circulating system for indirect heating. ANON. *Chem. Met. Eng.* 19, 733-5(1918).—Further description of the process mentioned in *C. A.* 12, 643. It is known as the "Merrill" system and the oil used is called "Meprolene." Typical applications are described. Advantages claimed over superheated steam are freedom from excessive pressures and leaks, with higher temp. of the circulating medium. The advantages over other oils is claimed to be freedom from decompn. or volatilization.

W. L. BADGER.

---

A fusion bomb for sulfur determination in coal (PARR) 21.

---

Oil-filtering apparatus. H. TEN WINKEL. U. S. 1,290,820, Jan. 7. The app. is adapted to sep.  $H_2O$  and other impurities from oil.

Specific-gravity bottle. A. T. HASSINGER U. S. 1,290,553, Jan. 7. A specific-gravity bottle (for detg. sp. gr. of liquids) is arranged with a thermometer and with a flexible bottom and a calibrated adjustment device for altering the position of the flexible bottom to vary the capacity of the bottle to compensate for temp. variations.

## 2. GENERAL AND PHYSICAL CHEMISTRY.

---

WILLIAM D. HARKINS AND E. B. MILLARD.

Science and the practical man. COSMO JOHNS. *Trans. Eng. Ceram. Soc.* 17, 372-8(1918).—A review of prominent scientific discoveries with notes on their later application. C. H. KERR.

The evolution of chemical symbols. I. W. D. HACKH. *J. Am. Pharm. Assoc.* 7, 1038-42(1918); cf. *C. A.* 12, 2313.—Historical discussion. L. E. WARREN.

Valence. WM. A. NOYES. *Science* 49, 175-82(1919).—An address. The development of the theory of valence is traced critically from its inception down to the modern ideas based upon the electron theory, and upon the consideration of + and -

atoms in org. compds. New expts. and ideas are as follows: Dry  $\text{NH}_3$  and  $\text{Cl}_2$  react forming  $\text{NCl}_3$ ; and a dry soln. of  $\text{NCl}_3$  reacts with dry  $\text{HCl}$  to form  $\text{NH}_4\text{Cl}$  and  $\text{Cl}_2$ . These facts seem to prove that  $\text{NCl}_3$  is formed by the addition of  $\text{Cl}_2$  to  $\text{NH}_3$  forming  $\text{NH}_3\text{Cl}^+\text{Cl}^-$ , followed by a splitting off of  $\text{HCl}$ , and a repetition of the process till all the H is gone. The decompn. of  $\text{NCl}_3$  by  $\text{HCl}$  is caused by the addition of the acid giving  $\text{NCl}_3\text{H}^+\text{Cl}^-$ , followed by the splitting off of a + and a — atom of Cl as free  $\text{Cl}_2$ . The analogy between these reactions and those which take place in the substitution of Cl for H in  $\text{CH}_4$  or  $\text{C}_6\text{H}_6$  recalls Michael's theory that addition compds. are first formed in such cases. The idea is advanced that such additions are always of two atoms or groups, one + and the other —; also, that atoms may form unstable compds. of higher valence when one of the new valences is + and the other —. The instability of such compds. is due to the fact that they contain two atoms or groups of opposite sign.

The formula  $\text{O} = \text{N} \equiv \text{N}$  is proposed for nitrous oxide rather than the usual  $\begin{array}{c} \text{N} \\ \parallel \\ \text{N} \end{array} \text{O}$ .

This structure takes account of the probability that one N atom remains + and the other — during the formation of  $\text{N}_2\text{O}$  from  $\text{NH}_4\text{NO}_3$ , and it also seems more in accord with the ease with which  $\text{N}_2\text{O}$  gives up its O.

R. H. LOMBARD.

The valence hypothesis of J. Stark. W. JACOBS. *Chem. Weekblad* 15, 1476–83, 1566–71 (1918).—An outline of Stark's theory of valence, with some of its applications.

GEORGE W. MORREY.

Kinetic theory of osmotic pressure and the Raoult Law. II. G. JÄGER. *Ann. Physik* 54, 463–80 (1918); *Sci. Abstracts* 21A, 308–9; cf. *C. A.* 7, 3866.—In his work on the osmotic kinetic theory of dil. solns., K. Jellinek has put forward various objections to the present author's interpretation of osmotic pressure and related phenomena. The author examines mathematically the general mechanism of osmotic pressure. He concludes that for the calcn. of the osmotic pressure the existence of the solvent can be ignored, while the dissolved substance may be regarded as existing in gaseous condition in the given vol. The internal pressure of a dil. soln. is investigated and an additional proof is given of the theorem that a dil. soln. must possess the same internal pressure as the pure solvent. The vapor tensions of dil. solns. are also examd.

D. MACRAE.

An indeterminateness in the interpretation of entropy as log W. MRS. T. EHRENFEST-AFANASSJEWA. *Proc. Acad. Sci. Amsterdam* 21, 53–7 (1918).—The ideas formed from purely combinatory reasoning do not form a satisfactory or conclusive foundation to direct our choice among many different standpoints to one in particular; the decision as to when the probability of the state of a system reaches a max. depends on the point of view of the investigator. Assuming a quantity of gas large enough to permit its division into a large number of parts, to each of which the laws of probability may be applied, log w for the whole is only equal to  $\Sigma \log w$  when the restriction, arbitrary from the point of view of combinatory reasoning, is made that in the parts only we consider all the possible permutations. If the whole system is regarded as a new object for combinations the probability of the distribution of a special state in the whole is not equal to the product of the probabilities of the parts corresponding to this state.

GEORGE W. MORREY.

Determination of the molecular complexity of liquid sulfur. ALEX. MITCHELL KELLAS. *J. Chem. Soc.* 113, 903–22 (1918).—The mol. complexity of liquid S was calcd. by the method of Ramsay and Shields from surface-tension measurements. At least 95% of the mobile S ( $\text{S}_x$ ) between  $115^\circ$  and  $160^\circ$  is found to have the formula  $\text{S}_8$ . At about  $160^\circ$  the reaction  $3\text{S}_8 = \text{S}_{18}$  appears to occur.  $\text{S}_{18}$  appears to be stable up to near the boiling point. The surface tension was measured by means of capillary

tubes at temps. between  $115^{\circ}$  and  $445^{\circ}$ . Trouble experienced on account of impurities ( $\text{SO}_2$ ,  $\text{SO}_3$ , and  $\text{H}_2\text{S}$ ) was overcome by distg. the S and boiling in dry N, the gases evolved being pumped off. In disagreement with the results obtained by other observers, the surface tension of S was found to fall continuously from the m. p. to the boiling point, being 48.2 dynes at  $280^{\circ}$  and 39.4 dynes at  $445^{\circ}$ . The density of liquid S was measured at 18 different temps. from  $115^{\circ}$  to  $445^{\circ}$  and was found to vary from 1.8084 at  $115.1^{\circ}$  to 1.6140 at  $445^{\circ}$ . If plotted against the temp. both surface tension and density show a "break" near  $160^{\circ}$ .  
D. MACRAE.

**Passivity of chromium.** A. H. W. ATEN. Amsterdam. *Proc. Acad. Sci. Amsterdam* 21, 138-50(1918).—The phenomena described in preceding papers (*C. A.* 12, 2266) are explained on the assumption that the potential of a Cr electrode in a soln. of a given Cr concn. is detd. by the density of the H charge. The various cases are discussed in detail, with the aid of a diagram in which the Cr potential is expressed as a function of the H concn.; the phenomena will depend on the H concn. in the Cr, large in electrolytic Cr, and on the rate of removal of the dissolved H from the Cr, or on the rate of evolution of H when anodically polarized.  
GEORGE W. MOREY.

**Course of the values of  $a$  and  $b$  for hydrogen at different temperatures and volumes.** III and IV. J. J. VAN LAAR. Fontanivent. *Proc. Acad. Sci. Amsterdam* 21, 2-15 (1918).—A continuation of *C. A.* 12, 2267.  
GEORGE W. MOREY.

**Variability with time of the distributions of emulsion particles.** L. S. ORNSTEIN. Utrecht. *Proc. Acad. Sci. Amsterdam* 21, 92-5(1918).—Mathematical.

GEORGE W. MOREY.

**The colors of colloids.** I. WILDER D. BANCROFT. *J. Phys. Chem.* 22, 601-30 (1918).—By means of a large number of quotations from standard works the author has laid the foundation for the discussion of the colors of colloids. Colors may be divided into two classes, pigmental and structural. The former are caused by the presence of a pigment that can be extd. by a suitable reagent, *e. g.*, the red color of a rose. Structural colors may be subdivided: (1) Those not dependent upon the presence of a pigment, *e. g.*, the white color of a lily, pulverized glass, gray hair, mother-of-pearl. (2) Those dependent upon the presence of a pigment, the color of which is modified by structure. Under this heading come, (a) objective structural colors such as blue and green feathers of birds; (b) subjective structural colors, those that vary with the angle of incidence of the light rays, *e. g.*, the brilliant flashing metallic tints of many birds.

E. B. SPEAR.

**Investigation on Pasteur's principle concerning the relation between molecular and crystallonomical dissymmetry.** V. Optically active complex salts of iridium-trioxalic acid. F. M. JAEGER. Groningen. *Proc. Acad. Sci. Amsterdam* 21, 203-14 (1918); cf. *C. A.* 12, 887.—Racemic  $\text{K}_3[\text{Ir}(\text{C}_2\text{O}_4)_3] \cdot 4\frac{1}{2}\text{H}_2\text{O}$  (completely isomorphous with the corresponding racemic Rh salt) was split into its optical components with strychnine; the rotation-dispersion of the strychnine salts of both *d*- and *l*-potassium iridium oxalate,  $[\text{Ir}(\text{C}_2\text{O}_4)_3](\text{C}_{21}\text{H}_{22}\text{N}_2\text{O}_2)_3 \cdot 3\frac{1}{2}\text{H}_2\text{O}$  and  $3\text{H}_2\text{O}$ , resp., both pale yellow needles, are given in tables and curves. The *d*- and *l*-potassium iridium oxalate were also measured; both the *d*- and *l*-strychnine salts have a greater mol. rotation than the corresponding K salts. The rotation of iridium salts is greater than that of the corresponding Rh salts, and the slopes of the dispersion curves of the corresponding iridium and Rh salts are quite different, showing the preponderant influence of the central atom. Crystallographic details of *d*- $\text{K}_3[\text{Ir}(\text{C}_2\text{O}_4)_3] \cdot \text{H}_2\text{O}$ , large, orange-colored, flattened, triangular bipyramids, are given; it is completely isomorphous with the Rh salt.

**VI. Fission of potassium rhodium malonate into its optically active components.** F. M. JAEGER AND WM. THOMAS. Groningen. *Proc. Acad. Sci. Amsterdam* 21, 215-

24(1918).—Racemic  $K_3[Rh(C_6H_4O_4)_2]$  was converted to the Ba salt, then split with the aid of cinchonine sulfate; the *l*-compd. containing  $\frac{1}{2}H_2O$  crystallizes out first from soln., while the *d*-compd., which seps. later, contains  $3H_2O$ . From these the *d*- and *l*-K salts were prepd.; detailed crystallographic descriptions of each are given, with drawings of typical forms. Both show anomalous rotation-dispersion.

VII. Optically active salts of the triethylenediamine-chromic series. *Ibid* 21, 225-30(1918).—Racemic  $[Cr(Eine)_3]Ir_3.H_2O$  ("Eine" representing triethylenediamine radical) is perfectly isomorphous with the corresponding Co and Rh salts; typical crystals are described and drawn, and the mol. rotation-dispersions of the active components measured.

GEORGE W. MOREY.

The Brownian movement. L. S. ORNSTEIN. Utrecht. *Proc. Acad. Sci. Amsterdam* 21, 96-108(1918).—A derivation of Einstein's equation for the Brownian movement from statistical mechanics. Contrary to the objections of van der Waals, Jr., and Snethlage (*C. A.* 10, 2821), Einstein's equation is correct as long as  $\beta t$  ( $\beta = 6\pi\mu a/m$ ) is large in respect to  $1 - e^{-\beta t}$ ; in practice the lowest limit for  $t$  is 0.01 sec. Development of the equation of van der W. and S. leads to results in conflict with the statistical mechanics of Gibbs, the starting point of their reasoning.

The theory of the Brownian movement and statistical mechanics. L. S. ORNSTEIN AND F. ZEMKE. *Ibid* 108-14.—Further discussion of the paper of van der Waals and Snethlage.

GEORGE W. MOREY.

Remarks on the resistance capacity of a dipping electrode. A. MASSINK. *Jaarversl. Centr. Lab. Volksgezondh.* 1917, 58; *Chem. Weekblad* 15, 1365(1918).—An explanation of the erratic behavior of the electrode in question as reported in a previous paper (*C. A.* 12, 2480).

JULIAN F. SMITH.

Magnetic susceptibility and electric sensitivity. F. H. LORING. *Chem. News* 117, 229-31(1918); cf. *C. A.* 8, 1698.—It is proposed to treat magnetic susceptibility as a compound effect analogous to that of the joint resistance of two parallel circuits according to the well known rule  $R = r_1 r_2 / (r_1 + r_2)$ . In this way magnetic susceptibility is considered to be calculable from the elec. resistivity and "the at. or mol. currents expressed in terms of positive and negative resistivity." The terms "at. or mol. currents" and resistivity are used in a general sense, or by way of analogy, and these expressions must not be interpreted too literally, *e. g.*, mol. currents may stand for a resultant effect involving the orientations of electronic orbits but governed by mol. conditions. It follows from this method of treatment that ferromagnetic substances might have negative mol. currents associated with resistances numerically less than, but of the same order of magnitude as, the currents, while diamagnetic substances might have negative at. currents, the resistivities being numerically greater than the currents. For example, in the case of diamagnetic substances, if the effect of the negative at. currents are expressed by  $-a$  and that of the resistivity by  $b$ ,  $-a.b/(-a + b) =$  (negative susceptibility).

D. MACRAE.

Calculation, by the cyclic method of Leduc, of the ratio of principal specific heats of benzene and cyclohexane. G. DÉJARDIN. *Compt. rend.* 168, 161-4(1919).—The method of getting  $\gamma = C_p/C_v$ , which is not described here, depends on the use of a thermodynamic cycle in which the liquid is included. The results, believed good to 1%, are, for benzene,  $\gamma = 1.106$  at  $20^\circ$ ,  $1.116$  at  $100^\circ$ ; for cyclohexane,  $\gamma = 1.077$  from  $20^\circ$  to  $90^\circ$ . The value for benzene at  $80^\circ$  would hold for a system of 3 rigid spheres located at the vertices of a triangle, for cyclohexane, for a system of 3 solids differing slightly from solids of revolution. The value of these resemblances is not to be exaggerated, but the importance, for the study of the kinetic theory of gases, of a knowledge of  $\gamma$  for vapors seems to be indicated.

W. P. WHITE.

**Mercury as a contact poison.** G. BREIDIG. *Techn. Hochschule, Karlsruhe i. B. Ber.* 51, 1477(1918).—In connection with the statement of Paal and Hartmann that thus far, to their knowledge, nothing was known as to the influence of metallic Hg on the catalytic properties of the hydrosols of the Pt metals (*C. A.* 13, 447), B. points out that in 1899 he and von Berneck (*Z. physik. Chem.* 31, 327) observed a decrease in the catalytic activity (in the decompn. of  $H_2O_2$  in non-alk. soln.) of a Pt liquid which was shaken with metallic Hg before being used. CHAS. A. ROUILLER.

**La Société des Chimistes français.** H. LANDOWSKI. *Ann. chim. anal. chim. appl.* 1, 1-3(1919).—Le Syndicat central des Chimistes français, established in 1890, was reorganized Aug. 4, 1917, as la Société des Chimistes français, with the objects "of protecting and developing the consideration due to the profession of the chemist, of obtaining treatment compatible with the studies he makes and the function he exercises and of trying to realize in the bosom of one society, all of whose members are friends, the union of all French chemists." Beginning with Jan. 15, 1919, the organ of the society will be *Annales de chimie analytique et de chimie appliquée*, formerly *Annales de chimie analytique*, starting with 2nd series, Vol. 1. E. H.

**The Naval Consulting Board of the United States.** W. R. WHITNEY AND L. H. BAEKHLAND. Members of the Board. *J. Ind. Eng. Chem.* 11, 248-9(1919).—A "provisional statement, not involving details," regarding the Board and its work. E. J. C.

**Gases used in warfare.** D. D. BEROLZHEIMER. *J. Ind. Eng. Chem.* 11, 256 (1919).—The list of "gases" is accompanied with references to the standard reference books. A few journal references are given. E. J. C.

**Bibliography on carbonyl chloride (phosgene) and its derivatives.** D. D. BEROLZHEIMER. *J. Ind. Eng. Chem.* 11, 263-6(1919). E. J. C.

**Prompt action by chemists needed on prohibition legislation.** JAMES R. WITHROW. *J. Ind. Eng. Chem.* 11, 253-4(1919).—With the passage of the prohibition amendment two kinds of chem. responsibility present themselves. "The first responsibility is that of watchful care over both national and state legislation so that those in charge of this legislation may be supplied with honest information which will prevent its lack bringing unnecessary hardship upon chemistry and those utilizing it, by unwise restrictions. The other responsibility is involved in the importance of every chemist eliminating, as rapidly as may be, the need for undenatured alcohol in every laboratory and manufacturing operation." E. J. C.

W. H. ROSS.

Ionization of mercury, sodium and potassium vapors and the production of low voltage arcs in these vapors. T. C. HEBB. *Phys. Rev.* 12, 482-90(1918); cf. *C. A.* 12, 1530.—The expts. prove that in the case of K and probably of Na ionization can occur at a voltage  $V$  given by the equation  $V_e = h\nu$ , where  $\nu$  is the frequency of the first member of the principal series of the element. These elements thus fall in line with Hg and more or less with the cases of H and He. It appears that ionization at the resonance voltage was due either to repeated collisions or to a combination of collision and photoelec. effect, but that in either case a minimum velocity of collision was necessary, this min. velocity corresponding to the resonant voltage. K vapor can be ionized at 1.6 v., its resonant voltage, while Na vapor can be ionized at 2.5 v., which is very close to its resonant voltage. The D lines of Na can be excited at less than 1.0 v. These results are in agreement with those of Wood and Okano (*C. A.* 11, 3163). The Na and K arcs in Hg vapor can operate below their resonance potentials and as low as 1.4 v. for Na and 0.5 v. for K. The Hg spectrum can be produced as low as 0.5 v. in an atm. of Hg and K.

A. L. FIELD.

The physical characteristics of X-ray fluorescent intensifying screens. MILLARD B. HODGSON. *Phys. Rev.* 12, 431-5(1918).—Lately the fluorescent screen has been employed to reduce the lengthy exposures of such X-ray spectroscopic investigations as are dependent on the photographic plate for record. Of the materials which fluoresce to X-rays in the range of frequencies from the ultraviolet to the red, there are only a few which can be used efficiently for photographic intensification. Of these, crystalline  $\text{CaWO}_4$  is by far the best. The efficiency of any radiator as a source of photographic stimulation depends primarily on the comparative spectral distribution of the energy of the radiator and the spectral sensibility of the particular photographic plate used. Photographs are given of the fluorescent spectra of  $\text{CaWO}_4$  obtained by a quartz spec-

trograph on an X-ray plate, a fast ordinary plate, an orthochromatic plate, and a panchromatic plate. In addition, photographs are given which show the spectral sensitivities to white light of the same plates. The fluorescence is certainly dependent primarily on the following factors: (1) selective absorption of the elements of the crystal compd. in the intensifying screen, (2) the frequency of the exciting radiation, and (3) the crystal structure of the  $\text{CaWO}_4$  used. The X-ray analysis of the latter will probably throw light on the subject. H. also finds that the characteristic radiations from metal screens, especially of Ag and Pt, are of practical value photographically.

Electric smelting of iron ores in British Columbia. ALFRED STANSFIELD. *Eng. Mining J.* 107, 224(1919).—Estd. consumption of power is 0.4 to 0.5 h. p. yr. per ton of Fe produced. The total cost of production per ton of pig iron for a plant consisting of 3 elec. furnaces, each of 3000 kw., is given as \$29.75.

H. JERMAIN CREIGHTON.

Polarization of Leclanché cell (and Weston cell). F. E. HACKETT AND R. J. FREELY. *Sci. Proc. Roy. Dublin Soc.* 15, 279-88(1918).—Due to polarization it is difficult to attain precise measurement of the internal resistance of the Leclanché dry cell. The authors found that the recovery of the cell after polarization follows the law for the velocity of bimolecular reactions obeyed by the ionization of gases. A Leclanché cell was connected in series with a resistance so adjusted that the initial current was 0.2 amp. Voltage readings were made every 10 min. The curves for the increase in polarization varied from test to test; on the other hand, the recovery curves were practically the same for all tests. Accordingly, attention was confined to the recovery curves, of which 30 in all were plotted. In the first ten min. the recovery voltage rose from 0.63 to 1.43, in another 60 min. to 1.47, and after 30 hrs. to 1.50 v. The process in the first 10 min. is probably due to an excess of + ions accumulated on the surface of the C electrode during polarization. The second or slow part of the recovery curve is due to diffusion, *i. e.*, the gradual elimination of concn. differences in the electrolyte which were brought about during polarization. If  $V$  represents the voltage at any time during the first rapid recovery stage,  $V_1^*$  that at the end of this first stage, and  $a$

a constant, then the velocity of the recovery can be expressed by the bimolecular equation  $dv/dt = \alpha(V_s - V)^2$ . In the case of the cell tested  $V_s$  was found to be equal to 1.32 volts and  $\alpha = 0.694$ . The agreement between observed and calcd. values is very good. Tests were also made on a Weston cell and the above equation was found to apply. Accordingly it seems probable that the equation is applicable to various types of polarized electrodes. C. G. F.

**Storage batteries.** O. W. A. OETTING. *J. Cleveland Eng. Soc.* 11, 95-102(1918).—Recent developments commercially are toward small units, i. e., isolated lighting units, automobile batteries and batteries for war purposes. No types have been developed using plates other than the Pb or the Ni-Fe elements. All changes were along lines of construction details and method of mixing pastes. 32-v. systems have been adopted as standard for isolated battery plants. Applications to auto starter service brought about high rates of discharge previously considered next to impossible with proper life. Normally an elec. starting motor draws current at a rate that will discharge the battery (i. e., lower voltage to about 1.5 v. per cell) in about 15 min. The Soc. of Automotive Eng. have standardized two rates for testing. One is to det. the lighting ability and calls for a discharge at normal temps. of 5 amps. The second rate is detd. by discharging at such a rate that the battery is discharged in 20 min. Its purpose is to det. the starting ability of a battery. By the term "five second voltage" is meant the voltage at the end of 5 secs. at a certain discharge rate, often 4 or 5 times the so-called 20-min. rate. The five-second voltages are used in detg. the proper size of battery needed for starting the engine, and also in designing the elec. starter. The factor that det. the size is mainly the power required to start the engine under cold weather conditions. At low temps. the battery capacity and thermal voltage are considerably reduced. The Fe-Ni alk. battery has not been applied to elec. starters, due to its high internal resistance, and its poor performance at low temps. At  $-12^\circ$  the Pb acid type has about 50% of its normal capacity, while the Fe-Ni battery is below 10%. Deterioration of Pb plates is largely due to overheating in summer time. A Pb battery will normally discharge itself on open circuit in about 100 days. Freezing of battery electrolyte can be avoided by keeping the cells fully charged, since in this condition the freezing temp. is about  $-60^\circ$ . A. L. FEILD.

**Removal of sediment from storage cells.** M. W. PULLEN AND F. F. SKRIVAN. *Elec. World* 73, 432(1919).—When cells cannot be dismantled for cleaning, deposits of active material collected at the bottom of cells can be removed by inserting a glass tube into the cell and drawing up the deposit with the aid of a filter pump and large bottle trap. One illustration. C. G. F.

**Pointers for the plater when buying equipment.** E. P. LATER. *Foundry* 47, 76-8(1919).—A discussion of the features to be considered when selecting the proper machines; the lining and use of tanks; the flow of electricity; and voltage regulation.

H. JERMAIN CREIGHTON.

**The deleterious effect of using saline oil coke in the manufacture of carbon electrodes.** H. SCRAGG. *J. Soc. Chem. Ind.* 37, 1237(1918).—Saline oil coke from Russia contains from 6 to 7% NaCl. It is possible that during calcination a loss of NaCl will occur. The presence of salt, however, seems to prevent as high a temp. being attained during calcination as is the case with saline-free coke, the temp. being reduced from 1100-1500° to 880-1100°. Thus the volatile NaCl would condense on the cooler coke at the top or drop back into the furnace. Instead of a loss, a process of concn. would go on until the furnace was drawn. In practice, it is found that the NaCl increased from 6% in the original to 8% in the calcined coke, and the insol. ash rose from 0.8 to 1.2%, the latter being probably due to the action of fused NaCl on the furnace lining. The density of the finished electrode should be at least 2.00, whereas with oil

coke containing 1.78% NaCl the density was 1.89. The low density must be due to (1) low temp. of calcining, (2) improper baking temp., or (3) to the NaCl preventing the escape of volatile matter. Many of the finished electrodes are blistered and have whitish marks on the surface. A. L. FIELD.

**The Davis oven for baking electrodes.** ANON. *J. four élec.* 28, 11-2 (1919).—The heating chamber of a Davis furnace measures 2.75 m. in width, 1.83 m. in length, and 2.75 m. in height, and can contain 6 electrodes having a diameter as large as 560 mm. The refractory lining of the furnace is of Scotch brick, the walls being 230 mm. in thickness. The top of the furnace is so constructed that it preheats the air used in the six gas burners by which the baking oven is indirectly heated. Each of these burners is connected with a gas and an air supply. By dividing the baking oven, it is possible to bake simultaneously electrodes at two different temps. The electrodes are held in the oven in a vertical position by holders of refractory material, and are maintained at a uniform temp. for several days. The max. variation in temp. is 50-60°. When employed in elec. steel furnaces, the consumption of electrodes baked in the Davis oven amounts to 5 kg. per ton of steel. H. JERMAIN CREIGHTON.

**Storage battery.** B. FORD. U. S. 1,289,146, Dec. 31. Structural features.

**Storage battery.** E. F. ANDREAE. U. S. 1,289,354-5-6, Dec. 31. Structural features.

**Storage battery.** M. MELIA. U. S. 1,290,487, Jan. 7. Structural features.

**Electric battery.** R. C. BENNER and H. F. FRENCH. U. S. 1,289,365, Dec. 31. Negative battery elements, for use with NaOH or other alk. electrolyte, are formed of Cu oxide with a binder of S. This prevents sifting out of the oxide when placed in perforated containers. The S is heated sufficiently to cause it to cement together the particles of oxide and may be used in amounts of from 0.5% to 40%. Its use also improves the electrochemical properties of the battery, giving high voltage and long life. Cf. C. A. 12, 882.

**Electric battery.** R. C. BENNER and H. F. FRENCH. U. S. 1,289,366, Dec. 31. In the manuf. of Cu oxide elements for elec. batteries with an alk. electrolyte such as KOH or NaOH, the Cu oxide is mixed with sufficient Se or Te to cement the particles of Cu oxide together. This bonding of the oxide particles prevents sifting out from perforated containers and also permits the molding of the electrode material into solid blocks if desired for use without perforated containers. Selenides or tellurides may also be used. Use of either Se or Te or their compds. has the effect of raising the voltage of the battery.

**Electric battery.** H. F. FRENCH. U. S. 1,289,433, Dec. 31. The pat. relates to structural features of a battery of the dry cell type.

**Electric battery.** W. C. BAUER. U. S. 1,289,609, Dec. 31. Elec. batteries are formed with an alkali metal hydroxide electrolyte, a Zn anode and a cathode comprizing  $\text{PbO}_2$  together with a chemical such as  $\text{Na}_2\text{S}$  or  $\text{NaOCl}$ , which will ppt. from the electrolyte the sol. Pb compds. which may form in it.

**Photosensitive electrical cells.** S. A. BERGLUND. U. S. 1,289,369, Dec. 31. The capacity of Se cells or other photo-sensitive cells is increased, and overheating of the cell avoided, by absorbing heat, as generated, from the cell during its operation.  $\text{H}_2\text{O}$ , air,  $\text{CO}_2$  or other heat-absorbing media may be used for abstracting the heat from the cell.

**Electrolytic cell and electrode therefor.** A. T. STUART. Can. 188,772, Feb. 18, 1919. The electrode has a rigid back and thin blades arranged at an angle to the back and spaced from one another, the blades engaging the back for the full length of the blades. The spaces between the blades are of the same width for the entire length of the blades.

**Manganese dioxide depolarizer for electric batteries.** C. ELLIS. U. S. 1,289,707, Dec. 31.  $\text{MnSO}_4$  or other Mn salt is dissolved and the soln. heated to the b. p. while Cl is introduced into it. Black  $\text{MnO}_2$  or some similar higher oxide of Mn forms and is pptd. and from time to time removed by filtration. As the soln. increases in acidity, the excess acid formed is neutralized. The acidity is not allowed to exceed 10%, but 2-5% acid may be present with formation of a deep black  $\text{MnO}_2$  which is adapted for use as a depolarizing material for batteries and does not cause local action in the battery when so used. Spent battery depolarizer material may be used in the process by dissolving it in acid and treating the soln. with Cl.  $\text{Na}_2\text{SO}_4$  or NaCl may be added to the Mn salt soln. to raise the b. p. so that the temp. of pptn. may be higher but usually this is not desirable, as it tends to cause the formation of complex manganites.

**Electric melting furnaces.** J. D. SHIPRON. Can. 188,727, Feb. 18, 1919. The electrodes project inwardly through the opposite walls of the melting chamber and a block of refractory conducting material insulated from the walls of the furnace is supported above the ends of each pair of electrodes.

**Electric furnace for alloying metals.** F. L. MCGAHAN. U. S. 1,290,268, Jan. 7. The furnace is especially adapted for smelting Fe ore and making alloy steels.

**Electric arc furnace for gas reactions.** A. V. LIPINSKI. U. S. 1,290,600, Jan. 7. The app. is especially adapted for making oxides of N or for the production of HCN, or for other reactions in which it is desirable that the gaseous products be cooled immediately after contact with the arc. A dispersed arc is produced against equidistant electrodes so that a flame sheet is formed bounded by the electrodes and cooling gas is supplied at different points of the flame sheet to maintain a supporting gas wall for the flame over its entire surface. Reacting gases are supplied to the other side of the flame and the reaction products are withdrawn from the flame at different points.

**Tungsten-reducing furnace.** C. A. PFANSTIEHL. U. S. 1,289,896, Dec. 31. The pat. relates to structural features of a tubular furnace for reducing  $\text{WO}_3$  in which the latter is drawn successively through independently heated sections of the furnace.

**Alumina from raw materials containing iron.** R. H. MCKEE. U. S. 1,290,269, Jan. 7. The process is designed to produce practically pure alumina from impure materials such as natural deposits of basic Al sulfate or the acid-sol. furnace residues remaining after the extn. of K from feldspars, sericite or other K-bearing silicates of Al. The raw material is ground and treated with  $\text{H}_2\text{SO}_4$  and is then subjected to a fractional electrolytic purification for the purpose of eliminating most of the Fe as hydroxide without pptg.  $\text{Al}(\text{OH})_3$ . The purified soln. is filtered off and allowed to flow through an electrolytic diaphragm cell in which the conditions are so regulated as to

effect as complete a pptn. of  $\text{Al}(\text{OH})_3$  as possible. Good results are obtained with a cathode current d. of about 1 amp. per sq. dm. and an anode d. of 0.3 amp. per sq. dm. or less, a voltage of about 6 and temp. of 20–50° (pptn. being somewhat better at the lower temps.)

Oxide coating on aluminium. P. MACGAHAN. U. S. 1,289,215, Dec. 31. In printing on Al, for production of clock dials, etc., the sheet Al is immersed in a soln. of a sol. silicate and subjected to the action of an elec. current to form an integral oxide coating on the metal, and, after washing and drying, the desired characters are printed on the oxidized surface thus formed.

Oxides of nitrogen from atmospheric air. J. L. LA COUR. U. S. 1,290,584, Jan. 7. In producing oxides of N from atm. air by passing a vol. of gas containing O and N repeatedly through an elec. arc in circuit, a leakage of air into the system is permitted and there is maintained in the circuit a % of O greater than that required for the reaction. During the circulation of the gases, there is removed from the circuit a gas mixt. rich in O and after sepn. from associated impurities the O is returned to the system. This mode of handling the gases obviates the need for a gas-tight furnace and prevents difficulties which might otherwise follow from the leakage of air into the circuit and the consequent accumulation of argon and other undesired gases in the app.

Separation of suspended particles from gases. H. A. BURNS. Can. 188,877, Feb. 25, 1919. Gases are passed through an elec. field in which a unidirectional discharge is maintained and a stream of fluid is interposed in the path of the charged particles and maintained on the surface of the pipes or collecting electrodes. App. is also specified.

Arc lamp electrodes. W. R. MORR. U. S. 1,289,514, Dec. 31. Rare-earth metals of the Yt group are used in flaming arc lamp electrodes with a C shell or body for the obtainment of a bright red light of high candle power which is especially due to the Yt. A HCl soln. of various rare earth metal compds. is satd. with  $\text{Na}_2\text{SO}_4$  or  $\text{K}_2\text{SO}_4$  at a temp. of 50–60° and allowed to stand to effect sepn. of Ce and other undesired rare earths, while leaving Yt in soln. The Yt material thus obtained is mixed with 30–60% of C and cored in C shells with a binder such as an alkali metal silicate, glucose or tar and benzene.  $\text{CaF}_2$  may be used together with the Yt and other rare earth compds. but the Yt compds. should exceed a 1:2 ratio with the other rare earths. For color photography and pan-chromatic photography, the crude Yt group of the Welsbach residue may be used in mixts. with  $\text{CaF}_2$ , SrF<sub>2</sub>, rare earth titanates and other compds. to secure the exact color effects desired without using a color screen or with only a very light color screen. The Yt compds. color the arc green when the arc springs from the Yt compds. themselves but produce a brilliant red coloration when the arc springs from C containing Yt. The best compds. of Yt for the purpose are  $\text{Yt}_2\text{O}_3$ ,  $\text{YtF}_3$ , or the mineral yttriofluorite. Metallic Yt also may be used. The Yt group compds. can also be added to solid flame carbons in which case they are mixed with C flour and a binder such as pitch, molded and baked in the usual way. The flaming material, consisting of Yt compds. and  $\text{CaF}_2$ , in such a carbon should constitute 20–60% of the entire electrode mass, the  $\text{CaF}_2$  constituting 0–50% of the mass.

## 6. INORGANIC CHEMISTRY.

H. I. SCHLESINGER.

Water of hydration. IV. Compounds with 2  $\text{H}_2\text{O}$  and 3  $\text{H}_2\text{O}$ . I. GUARESCHI. R. Univ., Torino. *Atti accad. sci. Torino* 53, 861–8; cf. C. A. 11, 3002.—The minimum temp. at which dehydration occurs, and the rate at which  $\text{H}_2\text{O}$  of hydration is lost,

have been detd. for the following salts:  $Sr(CHO_2)_2 \cdot 2H_2O$ : At  $30^\circ$ , which is the dehydration temp.,  $1 H_2O$  was lost in 40 hrs.,  $\frac{1}{2} H_2O$  in 48 hrs. more, and the final  $\frac{1}{2} H_2O$  after another 92 hrs. Under 20 mm. pressure over  $H_2SO_4$  at ordinary temp.,  $1 H_2O$  was lost after 70 hrs.,  $\frac{1}{2} H_2O$  after 25 hrs., and the last  $\frac{1}{2} H_2O$  only after another 120 hrs.  $H_2O$  of hydration is not regained on standing in air.  $Zn(CHO_2)_2 \cdot 2H_2O$ : Stable in air. At the dehydration temp.,  $70^\circ$ ,  $1 H_2O$  was lost after 24 hrs., and the second  $H_2O$  after another 40 hrs. At  $100^\circ$  all the  $H_2O$  is lost in 3-4 hrs. The anhydrous salt absorbs about  $1\frac{1}{2} H_2O$  upon standing in the air.  $Mn(CHO_2)_2 \cdot 2H_2O$ : The dehydration temp. is  $70^\circ$ , at which  $1 H_2O$  was lost in 74 hrs.,  $\frac{1}{2} H_2O$  after 46 hrs. more, and the final  $\frac{1}{2} H_2O$  only after another 168 hrs. The salt is stable in a desiccator over  $CaCl_2$  and  $H_2SO_4$ , and under 10 mm. pressure. The anhydrous salt regains its  $2 H_2O$  on long standing in air.  $Ca(ClO_3)_2 \cdot 2H_2O$ : The dehydration temp. is  $50^\circ$ . The dry salt regains its  $H_2O$  rapidly when exposed to air and is very deliquescent.  $K_4Fe(CN)_6 \cdot 6H_2O$ : The dehydration temp. is  $50^\circ$  in a thermostat,  $42^\circ$  in a current of air, and room temp. over  $CaCl_2$ . The last  $\frac{1}{2} H_2O$  is lost very slowly. In fact, in many of the above salts  $H_2O$  seems to be given off in fractions of mols., and the last  $\frac{1}{2} H_2O$  is given off much more slowly than the preceding  $H_2O$  mols. Since it is unlikely that  $\frac{1}{2}$  mol of  $H_2O$  actually exist, it is considered probable that metallic salts have a mol. wt. greater than that represented by their simple formulas. For example, the formulas  $Mn_3(CHO_3)_4 \cdot H_2O \cdot H_2O \cdot 2H_2O$  and  $Sr_3(CHO_3)_4 \cdot H_2O \cdot H_2O \cdot 2H_2O$  would permit of the  $H_2O$  being given off as whole mols., and at the rates observed above.

## 7. ANALYTICAL CHEMISTRY.

E. G. R. ARDAGH.

Approximate atomic weights for use in chemical analysis. N. SCHOORL. *Z. anal. Chem.* 57, 209-25 (1918).—See *C. A.* 12, 1625. JULIAN F. SMITH.

A method for determining the composition of a mixture of similar salts of two metals, without separating the mixture into its constituents. H. N. WILSON. *Chem. News* 118, 3-4 (1919).—The method is based on the detn. of the common anion and calcn. of the amts. of the 2 salts present, e. g.,  $NaCl$  contains 60.65%  $Cl$ ,  $KCl$ , 47.55%, so that 0.00%  $NaCl$  and 100%  $NaCl$  are the limits of a mixt. of the two salts (or 60.65 and 47.55%  $Cl$ , respectively); while the % of  $Cl$  rises 13.098%, the %  $NaCl$  rises 100, so when the %  $Cl$  rises 1.00 the %  $NaCl$  rises 100.00/13.098 or 7.6346; therefore det. the %  $Cl$  in a mixt. of the chlorides (free from impurity), subtract the minimum possible %  $Cl$  (47.55) in the mixt. from the % found and multiply the result by 7.6346, obtaining %  $NaCl$  present;  $KCl$  is obtained by difference. W. suggests the method for the detn. of total alkali in flue dust. The method may be applied to other cases, e. g., detn. of  $Ba$  in a mixt. of  $CaCO_3$  and  $BaCO_3$ , the results being calcd. from the %  $CO_3$  found. F. W. SMITHER.

Volumetric determination of barium. THOS. STEEL. *Analyst* 44, 29 (1919).—In connection with Waddell's paper (*C. A.* 12, 2175) S. suggests washing the ppt. with  $H_2O$  satd. with  $BaCrO_4$ . This serves better than correcting for soly. in  $H_2O$ .

ERLE M. BILLINGS.

A physico-chemical method of determining alkali carbonates in the presence of alkali hydroxides. Application to the analysis of flue gases. RENÉ DUBRISAY,

TRIPPIER AND TOQUET. *Compt. rend.* 168, 56-9(1919).—The method is based on the diminution of the coeff. of reciprocal miscibility of  $H_2O$  and  $PhOH$  by alkali carbonates. The authors prepd. solns. of  $Na_2CO_3$  and  $NaOH$  (2 *N* to 0.25 *N*), united those of same normality, and mixed 50 cc. aliquots with 50 g. of  $PhOH$ ; the mixts were heated until complete soln. resulted, then let cool and the temp. was noted at which turbidity appeared, following the method of Rothmund (cf. *C. A.* 2, 2476). From the data obtained curves were plotted, the abscissas showing the %  $Na_2CO_3$  and the ordinates the temp. To apply the method to an unknown mixt., det. the total alkali by titration, make up to a suitable concn. (e. g., 40 g. per l.), mix 50 cc. with 50 g. of  $PhOH$ , and proceed as above. From the turbidity temp. found and the appropriate curve (in this case *N*), the %  $Na_2CO_3$  is noted. The turbidity point can be easily detd. to 0.1°. To det.  $CO_2$  in flue gases bubble 1 l. of the gas (requires about 30 min.) through 71.5 cc. of 0.25 *N*  $NaOH$  soln., det. the % of  $Na_2CO_3$  by the above method. using a curve plotted for 0.25 *N* solns., and calc. the %  $CO_2$ . Results are reported showing excellent agreement with those obtained by direct analysis. Cf. Chopin, *C. A.* 13, 67. F. W. SMITHER.

A critical study of the Ledebur method for determining oxygen in iron and steel. J. R. CAIN AND EARL PETTIJOHN. *Bur. Standards, Tech. Paper* 118, 33 pp.(1919).—An exptl. study reported in detail. Errors in the method and their remedies are discussed. Special methods for prepg. samples are given and new forms of app. are described. The metallurgical significance of the results obtained by the L. method is pointed out. It is shown that: "(1) The L. method requires extraordinary precautions to obtain reliable results. The errors described undoubtedly affect in greater or less degree nearly all results by this method that have been described in the literature, and if these are approximately correct, it is because of compensating errors; (2) the L. method as described detns. with certainty only oxides of Fe, Mn above  $MnO$ , and Ni, Cu, and W, if the latter 3 ever exist in steel. In turn, such oxides are detd. correctly only in case they exist in the metal uncombined as silicates, which probably seldom happens; (3) L. O detns. show no distinguishing features for acid Bessemer, basic or acid open-hearth, duplex, elec. furnace, or crucible steel (American manuf.); (4) L. O detns. show no differences in steels deoxidized with a variety of deoxidizers. In view of these facts we believe that the method is of little practical value, and that it must be superseded by others which are more positive and more specific in the information they yield."

F. W. SMITHER.

Tentative methods for chemical analysis of alloys of lead, tin, antimony and copper. ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 502-9(1918).—Methods compiled from the literature are given in detail and include: (1) a general method (cf. Thomson, *J. Soc. Chem. Ind.* 15, 179(1896)); (2) rapid volumetric procedure for factory control (molybdate method for Pb; Pearce-Low I method for Sn;  $KMnO_4$  method for Sb; pptn. of Cu as  $CuCNS$  with ignition and soln., completing by the KCN or  $KI-Na_2S_2O_3$  methods).

F. W. SMITHER.

Tentative methods for chemical analysis of manganese bronze. ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 510-22(1918).—Methods compiled from the literature are given for the detn. of: Cu and Pb electrolytically, Pb as  $PbSO_4$ , Sn by weighing as  $SnO_2$ , Fe by  $KMnO_4$ , Mn by  $(NH_4)_2S_2O_8$  and Na bismuthate.

F. W. SMITHER.

Tentative methods for chemical analysis of gun metal. ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 523-37(1918).—Methods compiled from the literature are described in detail and include the following detns.: Cu (electrolytically), Sn (in the presence and absence of P), Pb (electrolytically and as  $PbSO_4$ ), Zn (by weighing as  $ZnSO_4$ ), P (alkalimetrically and by  $KMnO_4$ ).

F. W. SMITHER.

The evaluation of zinc dust: a proposed method of analysis. L. A. WILSON. *Proc. Am. Soc. Testing Materials* 18, Pt. II, 220-34 (1918).—See C. A. 13, 14.

F. W. SMITHER.

The determination of carbon dioxide in carbonates. DONALD D. VAN SLYKE. Rockefeller Inst. *J. Biol. Chem.* 36, 351-4 (1918).—The method is applicable to all carbonates, sol. and insol., in the absence of acids, such as  $H_2S$ , that are highly volatile from  $H_2O$  soln. It was devised primarily for the detn. of carbonate in bones which had been dried and pulverized but not ashed. Place the carbonate, either pulverized or in soln., in the bottom of a tube 20-25 mm. in diam. and place the tube in a 250 cc. suction flask (Fig.), containing an excess of 0.1 N  $Ba(OH)_2$  soln. When using a pulverized carbonate, weigh the tube, slip into it a roll of glazed paper to protect the walls, pour in the substance and reweigh the tube after withdrawing the paper. Evacuate the flask to a pressure of 50 mm. or less and close the outlet with the screw clasp. Admit an excess of N HCl, usually about 5 cc., slowly from the dropping funnel, leaving some of the acid above the stopper to insure its remaining air-tight. After the rapid evolution of  $CO_2$  has ceased, agitate the solns. with a rotary motion for 3 min. completely to transfer the  $CO_2$  from the inner tube to the  $Ba(OH)_2$  soln. Release the vacuum and remove the  $BaCO_3$  by filtration through a Gooch crucible, rinsing the flask and crucible with 3 portions of about 20 cc. each of  $H_2O$ . Titrate the filtrate with 0.1 N HCl, using phenolphthalein as indicator. In the analysis of dried pulverized bones which have not been ashed, 5 hrs. should be allowed for the acid to penetrate into the particles which are permeated with fat and protein; the solns. are stirred occasionally by rotation during that period and for 3 min. at the end of it. The fact that the entire process is carried out in a single closed vessel practically excludes error from the loss of  $CO_2$ .

A. P. LOTHROP.

Estimation of small quantities of ether in alcohol. H. E. Cox. *Analyst* 44, 26-7 (1919).—For very small quantities the methods of Fleischer and Frank (C. A. 1, 2912) and Wolff (C. A. 5, 561) are not satisfactory. Exptl. errors are large when density detns. are used, although the latter give fair results. A slight decrease in vol. is observed when equal vols. of  $Et_2O$  and  $EtOH$  are mixed. This amounts to about 0.5% of the total vol. "The presence of 0.25%  $H_2O$  will mask the effect of 1% of  $Et_2O$ ; and as 100%  $EtOH$  is very rarely met with, it is not sufficient merely to det. the density and refer to a table.  $EtOH$  of 99% and upwards distils over unchanged under ordinary conditions; any  $Et_2O$  it contains passes over in the first fractions and no const. boiling mixt. is formed. The density of the  $EtOH$  is taken as that obtained after the removal of the  $Et_2O$  (by distn.)." The expression  $[D(EtOH) - D(mixt.)]/0.0007 = \text{amt. of } Et_2O \text{ is used}$ . The Perkin type of pycnometer with glass caps was used for density detns. When distn. is necessary a Young's rod and disk still-head and double surface condenser are used. The receiver should be in a freezing mixt. and a  $CaCl_2$  guard tube is quite necessary. Results of expts. are tabulated.

SMITH, GEORGE MCPHAIL: *Quantitative Analysis*. New York: The Macmillan Co.

## 8. MINERALOGICAL AND GEOLOGICAL CHEMISTRY.

EDGAR T. WHERRY AND J. H. BOWER.

Two new zircon minerals, *orvillite* and *oliveiraite*. T. H. LEE. *Revista Sociedade Brasileira Ciencias* 1917, 31-8. Translation. J. C. BRANNER. *Am. J. Sci.* 47, 126-32 (1919).—Specimens of zirconiferous rock from Caldas, State of Minas Geraes, Brazil, gave on analysis:  $\text{Al}_2\text{O}_3$  0.15,  $\text{ZrO}_2$  71.88,  $\text{TiO}_2$  0.62,  $\text{FeO}$  0.43,  $\text{SiO}_2$  25.31,  $\text{H}_2\text{O}$  1.56, sum 99.95%. By treatment with a mixt. of HCl and HF the mineral was decompd. and a residue of  $\text{ZrO}_2\cdot\text{SiO}_2$  obtained, which was 41% of the original rock and contained one-half of the  $\text{SiO}_2$ . On sepg. homogeneous material from a new specimen by means of a needle and microscope, the sepd. part gave:  $\text{ZrO}_2$  68.04,  $\text{SiO}_2$  25.45,  $\text{H}_2\text{O}$  and vol. matter 6.35, corresponding to  $8\text{ZrO}_2\cdot 6\text{SiO}_2\cdot 5\text{H}_2\text{O}$ . As the identification of this mineral was due to the work of Orville A. Derby, the name *orvillite* is proposed. Samples of a mineral from Pomba, Minas Geraes, Brazil, gave on analysis:  $\text{Ta}_2\text{O}_5$  1.46,  $\text{Cb}_2\text{O}_5$  and  $\text{ZrO}_2$  36.39,  $\text{TiO}_2$  25.00,  $\text{CeO}_2$  0.46,  $\text{Yt}_2\text{O}_3$  (group) 23.08,  $\text{UO}_2$  10.06,  $\text{PbO}$  0.14,  $\text{H}_2\text{O}$  2.41, sum 99.00%. A quantity of homogeneous material sepd. under the microscope gave:  $\text{ZrO}_2$  63.36,  $\text{TiO}_2$  29.92,  $\text{H}_2\text{O}$  6.48, sum 99.76%, corresponding to  $3\text{ZrO}_2\cdot 2\text{TiO}_2\cdot 2\text{H}_2\text{O}$ . The name *oliveiraite* is proposed for this mineral, in honor of the veteran Brazilian geologist, Francisco de Paula Oliveira. L. W. RIGGS.

The supposed case of tin in statu nascenti in the Malay Peninsula. W. R. JONES. *Geol. Mag.* 1, 537-41 (1914).—Analyses of geyserite and the waters of the hot springs from Ayer Panas and Cheras failed to show traces of Sn. It is suggested that Meunier's cavernous opal "similar to geyserite, but containing Sn as a peculiar and characteristic constituent" (*Compt. rend.* 110, 1085) was a specimen of weathered cassiterite-bearing quartz obtained a short distance from the hot springs at Cheras.

S. G. GORDON.

A graphic intergrowth of diopside and ilmenite from the Bembesi Diamond Field, Southern Rhodesia. A. M. MACGREGOR. *Trans. Geol. Soc. S. Africa* 18, 1-4 (1916).—Estn. of the % of ilmenite, by the sp. gr. of the mixture, gave values ranging from 21.85 to 29.3%, and calcns. from the areas shown in thin section gave 26.35 to 32.06%. The possible explanations of the mixture are that it is a segregation from the kimberlite, or a cognate xenolith brought up in a solid state from the fundamental basin. If the first explanation is adopted, the intergrowth is a warning that a graphic structure is not necessarily an indication of the last stages of solidification or of eutectic compn.

S. G. GORDON.

Occurrence of radioactive minerals in South Africa. A. W. ROGERS. *Trans. Geol. Soc. S. Africa* 18, 5-10 (1916).—Monazite, euxenite and fergusonite occur in gravels, with cassiterite, corundum, scheelite, magnetite and garnet, in Embabaa Swaziland, supposedly derived from the gneissic rocks of the region. Euxenite occurs in pegmatites at Kenhardt. Tantalite and columbite occur in lumps and crystals (one group weighed 16 lbs.) in pegmatite with feldspars, quartz, muscovite, lepidolite, garnet, beryl, and spodumene in Little Namaqualand. Analyses of euxenite, columbite and tantalite are given.

S. G. GORDON.

Description of a carbonaceous mineral occurring in the Witkop mine, near Zeerust, Transvaal. C. ANDERSON. *Trans. Geol. Soc. S. Africa* 18, 129-31 (1916).—The mineral occurs as spherical or irregularly rounded pellets up to  $\frac{3}{4}$  inch, imbedded in calcite, and in one case, in vein quartz. The carbon occurs in two forms: anthraxolite, black, lustrous, highly polished, brittle, sp. gr. 1.845,  $H = 3-4$ ; and schungite, duller in appearance, soft enough to mark paper, sp. gr. 1.122. Analyses by J. C. H. Mingaye gave: anthraxolite, C 92.74, H 0.81, N and O 1.57, S 0.45,  $\text{H}_2\text{O}$

2.90, ash 1.53 = 100%; schungite, C 98.29, H 0.72, N, O, and S 0.29, ash 0.70 = 100%.  
S. G. GORDON.

**The future of British mineral resources.** H. LOUIS. *Nature* 102, 366-7(1919).—An abstr. of a report by Lionel Phillips, Controller of the Dept. for the Development of Mineral Resources in the United Kingdom. It is shown that the production in Great Britain of the minerals Pb, Sn, Zn and Cu is far short of the consumption, and it is suggested that there be formed a Mines Dept. which will have for its object the study and encouragement of the home mineral industry. W. H. ROSS.

**Genesis of the ores at Tonopah, Nevada.** EDSON S. BASTIN AND FRANCIS B. LANEY. U. S. Geol. Survey, *Professional Paper* 104, 47 pp.(1918).—The following are some of the more important conclusions: The hypogene or primary ores have been modified in places by oxidation and enrichment through the agency of the air and oxygenated solns. originating at or near the surface. The high Ag content of much of the ore obtained in the past and of some ore now remaining is due in part to these processes. There is evidence of recent oxidation of the ores, also of at least one period of ancient oxidation. Supergene sulfide enrichment was probably an accompaniment of each of these periods. The rich ores now mined in this region are believed to be of primary origin. Mining has shown that in certain veins the primary sulfides become less abundant with increasing depth, though the same species are present; mere increase in depth may account for this change in some veins, for every vein must end in depth as well as laterally; in many veins change in wall rock has been a contributing factor. The veins developed by other deep workings are heavily mineralized and of high grade, and the geologic evidence is favorable to the persistence of rich primary Ag ores to depths considerably greater than those yet attained in mining operations. Although hot ascending waters are encountered in a number of the deeper workings, there is little evidence that these waters are now depositing ores. L. W. RIGGS.

**The factors influencing gold deposition in the Bendigo Goldfield.** II. F. L. STILLWELL. Commonwealth of Australia, Adv. Council of Sci. and Ind., *Bull.* 8, 47 pp.(1918); cf. *C. A.* 13, 299.—An inspection of the auriferous reefs at Maldon on the southern side of the Harcourt granodiorite massif has provided further evidence of the nature of the relation of the reefs to the granodiorite. Numerous reefs at Maldon can be traced along their strike to the edge of the granodiorite where they peter out, the reefs occurring around the whole periphery of the granodiorite mass. Five analyses of the carbonate in the Bendigo reef indicate that the carbonate is not always ankerite, but sometimes calcite and pistomesite. Beds of sandstone sometimes pass into masses of quartz, the matrix having been replaced by the mineral solns., and the quartz grains of the sandstone further enlarged. Evidence is presented that the faults are older than the reefs. Movement has occurred along some of the fault planes after deposition of the quartz, with the production of quartz "pug" and slickensided quartz. Spurry systems occur, many of the spurs having developed by the infiltration of the mineral solns. from backs, faults, and porous beds into other fractures. The growth of a spur proceeds from a fracture by pushing the wall apart; at the same time a replacement of the country rock frequently occurs. Spurs sometimes appear to have developed in porous beds like sandstone by crystn. of the material enclosed in the pores. Saddle reefs usually show some evidence of replacement, and are the combined result of growth from fractures and replacement, having developed where arched fractures, formed over the anticline during the period of folding, are crossed by radial fractures. Faulting modifies the forms of the saddle reefs. Further examples have been observed in which enrichments have occurred in leg reefs in the neighborhood of the intersection with faults or cross-spurs. The size of the gold shoot seems to depend in part on the volume of the mineral solns. that issued from the particular fracture. If a Au-bearing spur is

partly formed by replacement, the Au may be localized in the neighborhood of the slaty laminas, which may be considered to have pptd. the Au. If lined with ankerite, the Au appears along the walls of the spur between the ankerite and the quartz, this relation indicating that ankerite has been a precipitant of the Au. In view of the persistence of the saddle reefs along their strike, it is probable that the flow of the mineral solns. in the longitudinal direction has been important, Au shoots occurring where the solns. are brought into contact with a precipitant.

S. G. GORDON.

**Geology and ore deposits of the Yerington District, Nevada.** ADOLPH KNOFF. U. S. Geol. Survey, *Professional Paper* 114, 66 pp.(1918).—The general geology and petrography of the district is given. The main ore bodies are Cu-bearing deposits characterized by a gang of either pyroxene, garnet, or epidote, or a mixt. of these minerals. Chalcopyrite is the chief Cu-bearing mineral; pyrite is commonly associated with it but no other primary sulfides occur in the district. The primary and secondary minerals of the ore deposits are described and many analyses quoted.

L. W. RIGGS.

**The oxidized zinc ores of Leadville, Colorado.** G. F. LOUGHLIN. U. S. Geol. Survey, *Bull.* 681, 87 pp.(1918).—Although the existence of Zn in this locality has been known for 30 years, it was not until 1910 that the importance of this occurrence was realized. A brief description of the mines and output is given. By far the most abundant ore is smithsonite, which is fully described and illustrated. Hydrozincite,  $\text{ZnCO}_3 \cdot \text{Zn(OH)}_2$ , aurichalcite,  $2(\text{Zn,Cu})\text{CO}_3 \cdot 3(\text{Zn,Cu})\text{(OH)}_2$ , calamine,  $\text{H}_2\text{Zn}_2\text{SiO}_5$ , hetaerolite ("wolfontite"),  $2\text{ZnO} \cdot 2\text{Mn}_2\text{O}_3 \cdot \text{H}_2\text{O}$ , and chalcophanite,  $(\text{MnZn})\text{O} \cdot 2\text{MnO}_3 \cdot 2\text{H}_2\text{O}$ , occur in varying amts. Five analyses of zinciferous clays are quoted, four of which show 31.49 to 35.40% of ZnO. More than a dozen of associated minerals are described. Fifteen pages are devoted to a chem. discussion of the genesis of the ores.

L. W. RIGGS.

**Genesis of the zinc ores of the Edwards District, St. Lawrence County, N. Y.** C. H. SMYTH, JR. N. Y. State Mus., *Bull.* 201, 40 pp.(1918).—The ore deposits occur in a belt of Pre-Cambrian, Grenville, metamorphosed limestone, with minor amounts of schist, quartzite, etc. On the north the limestone is overlain by schist, cut by pegmatite, granite and injected granitic material. To the south of the limestone there is an extensive area of younger granite, intrusive in the sediments. The ores form veins or irregular masses, sometimes sharply defined with well marked walls, again as irregular mineralized portions of the limestone, but cutting across its stratification. The ore is a compact, granular aggregate of sulfides, pyrite, sphalerite, and sometimes a little galena, with varying amts. of calcite, diopside, tremolite, phlogopite, serpentine, talc, barite, and occasional films of secondary greenockite. A peculiar mineral occurs in small amt., with a vermicular habit, identical with leverrierite except in its pleochroism. The limestone is a cryst. aggregate of calcite, with varying amts. of diopside, tremolite, phlogopite, serpentine, talc, and doubtful weathering products. Diopside has altered to serpentine, the latter having replaced calcite to a certain extent; tremolite has altered to talc. As talc is less hydrated than serpentine, it formed at a higher temp. on the descending temp. scale of metamorphism, and is distinctly older. Some serpentine has developed at the expense of the talc. The sulfides have replaced calcite and the silicates. The major part of the sphalerite was formed before the serpentine, but a generation of lighter colored sphalerite formed during the period of hydrothermal alteration. The silicates of the limestone are due to contact metamorphism, which, due to the thorough injection by granitic material, is regional, rather than local, in effect. The ore deposits are classed as of high-temp. type, with the sequence (1) diopside, tremolite, developed by contact metamorphism; (2) pyrite; (3) sphalerite; (4) galena, (5) talc, (6) serpentine; controlled by decreasing temperature. Throughout the process

calcite was subjected to repeated soln. and recrystn. The granite magma is considered the source of the ores, and of the solns. effecting the alteration of diopside and tremolite to serpentine and talc.

S. G. GORDON.

Geology and mineral deposits of the Colville Indian Reservation, Washington. J. T. PARDEE. U. S. Geol. Survey, *Bull.* 677, 180 pp.(1918).—The geography, geology and metalliferous deposits, including mines and prospects, are described. Omak Lake in this region has an area upwards of 3500 acres, the water containing 5566 parts per million of total solids which may be combined as  $K_2SO_4$  9.93,  $Na_2SO_4$  22.62,  $Na_2CO_3$  57.20, other salts 10.25%. A bay covering 400 acres is connected with the lake by a strait 400 ft. wide and might perhaps be used as an evap. basin. L. W. RIGGS.

Potash in saline waters in Saskatchewan. D. B. DOWLING. Canada Geol. Survey, Dept. Mines, *Summary report* 1917, Part C, pp. 36-46(1918).—Analyses of waters from northeastern Saskatchewan, the shales of Pembina Mountain, the gumbo derived from the washing of shales into the Red River Valley, and the boulder clay of the Regina district, show appreciable K. Water at Quill Lake at Wynward showed: KCl, 16.33 parts per 100,000. An analysis of water from Talmage gave: Na and K sulfates 117.992 and Na and K chlorides 0.970 part per gallon. Boring for K is in progress near Weyburn.

S. G. GORDON.

The deposits of potassium salts of Dallol, Eritrea. M. GIUA. *Gass. chim. ital.* 48, II, 1-8(1918).—The KCl deposits of Dallol, northern Danalia, Eritrea, have been mentioned at various times. Many samples of Na and K minerals were analyzed. The  $H_2O$ -insol. portion was composed of about 90% hydrated Fe oxide with traces of S,  $Al_2O_3$ , and  $SiO_2$ . The analyses of 15 KCl specimens showed 23.00 to 98.60% KCl (8 were over 90%). Most of the remaining  $H_2O$ -sol. material was NaCl, although  $MgCl_2$ ,  $MgSO_4$ , and  $CaSO_4$  were present in small amts. and sometimes as much as 2.00%. The insol. residue varied from 0.03 to 11.00% and in 4 cases exceeded 7.00%. Analyses of 17 NaCl minerals showed 16 above 57.45% NaCl, 1 with 6.00 and 7 over 94.20% NaCl. In only 6 specimens was KCl found and then did not exceed 2.00%.  $MgCl_2$ ,  $MgSO_4$ ,  $Na_2SO_4$ , and  $CaSO_4$  were mostly present in small amts., but never over 2.53%. The  $H_2O$ -insol. residue varied from 0.02 to 46.65% in 16 cases and was 80.97% of the sample containing 6% NaCl. The important known K salt deposits besides that of Stassfurt are those of Wittelshain, Santander (Spain) and Tarapan, (Chili). In their importance the deposits of Dallol are only to be compared with those of Stassfurt. The Stassfurt deposits containing KCl are difficult of access while those of Dallol lie largely on the surface. The purity of the minerals is such as to indicate that the deposits are not formed stratigraphically. Only a trace of Br is present. Thermal springs of  $MgCl_2$  (80-90°) occur in this same region so rich in  $MgCl_2$  that they solidify on cooling. Satd.  $MgCl_2$  springs (about 40°) also occur here. Further data on these subjects will be reported later.

E. J. WITZEMANN.

The Adirondack graphite deposits. HAROLD L. ALLING. N. Y. State Mus., *Bull.* 199, 150 pp.(1918).—Graphite deposits occur in Essex, Warren, Washington, and Saratoga counties, in a district of Pre-Cambrian, Grenville, cryst. limestone, quartzite, para-schist and gneiss, into which have been intruded granite (now gneissic), metagabbro, anorthosite, syenite and diabase of Laurentian and Algoman age. The various deposits and prospects are described in detail, with maps and quant. microscopic analyses of the ore. The graphite in the northern area occurs as contact deposits, most commonly between pegmatite and limestone, but also between pegmatite and biotite-hornblende schist, amphibolite and quartzite, and in other cases between syenite and gabbro with limestone and other sedimentary rocks. Graphite is not, however, always developed at the contact of an igneous and sedimentary rock. The contact de-

posits usually appear striking and exceedingly rich, but they prove to be too uncertain, too pockety, and too limited in extent to pay for mining, while the milling of graphite is still in the exptl. stage. The commercial deposits are the bedded deposits of the graphitic schists of the southern area which include normal quartz schist, feldspar-quartz-schist, a metaarkose, and a phase of the Dixon schist mildly contact-metamorphosed with the development of pyroxene and tourmaline and the redistribution of the graphite, resulting in an abnormally high content in certain layers. The concn., milling problems, and comm. status are discussed. After reviewing the various theories of the origin of the graphite, A. concludes that the deposits in the schists and metaarkose are of organic origin, and those of the contacts and veins inorganic.

S. G. GORDON.

**Graphite in Port Elmsley District, Lanark County, Ontario.** M. E. WILSON. Canada Geol. Survey, Dept. Mines, *Summary Rept.* 1917, E, 298-42e(1918).—The graphite deposits occur in a region of Pre-Cambrian limestones, pyroxene-gabbro, pyroxene syenite, hornblende-biotite granite and syenite, metamorphic pyroxenite, Paleozoic sediments, and unconsolidated quaternary deposits. The graphite deposits occur in the Pre-Cambrian basal complex, mainly in a highly silicated Grenville limestone, with which are associated a small amt. of quartzite and considerable masses of monzonite and orthoclase-pegmatite. The richest ore-bodies occur at the crests of folds, or at other points where the structure relationships indicate that a relief of pressure has occurred. Low-grade ore containing 4-6% graphite consists mainly of calcite with disseminated silicates; high-grade ore containing 15-20% graphite consists mainly of silicates—diopside, orthoclase, titanite, calcite, graphite and pyrite. The relationships can be accounted for on the assumption that the graphite is due to emanations from igneous intrusives, or was derived from the  $\text{CO}_2$  of the limestone by reduction. The association of graphite with zones of silication in the limestone, and increase in amount with intensity of silication, would seem to indicate that the graphite was in some way associated with the pegmatite intrusions, which effected the silication of the limestone. Gaseous or aqueous emanations would tend to accumulate at the crests of folds. There would likewise probably be a greater accumulation of graphite at such points whether it emanated from the igneous intrusives or was derived from  $\text{CO}_2$  set free by silication of the limestone.

S. G. GORDON.

**Geological reconnaissance for phosphate and coal in southeastern Idaho and western Wyoming.** ALFRED R. SCHULTZ. U. S. Geol. Survey, *Bull.* 680, 81 pp. (1918).—Phosphate deposits are generally distributed throughout this region. Analyses of 10 samples showed several containing the equiv. of 70%  $\text{Ca}_3(\text{PO}_4)_2$ . The rock now shipped from this region is sent to the Pacific coast. The chief obstacle to the development of these deposits is the cost of transportation. Beds of coal have been found in several localities in this field, and are at present being mined in a few places. The coal is of the bituminous variety. Rejecting one sample out of 7, the remaining 6 as obtained from the mine gave: H, varying from 4.81 to 5.94; C, 66.18 to 70.34; N, 1.29 to 1.52; and B. t. u., 11440 to 12880.

L. W. RIGGS.

**The geology of the Swaziland Coalfield.** J. JERVIS GARRAD. *Trans. Geol. Soc. S. Africa* 17, 75-84(1915).—The physical and geological features of the district are described, and analyses of the coal given.

S. G. GORDON.

**The Arnprior-Quyon District, Ontario and Quebec.** M. E. WILSON. Canada Geol. Survey, Dept. Mines, *Summary Rept.* 1917, E, 42e-43e(1918).—Molybdenite deposits occur in the Ottawa Valley as: segregations with pyrite, pyrrhotite, fluorite, quartz and orthoclase in quartz syenite; veins with pyrite; pyrrhotite and quartz in granite gneiss; in pegmatite dikes and feldspathic quartz veins; in contact metamorphic

deposits. Veins of galena, calcite, fluorite and barite are of common occurrence in the Ottawa Valley intersecting the Paleozoic and older rocks. S. G. GORDON.

Peace River Section, Alberta. F. H. McLEARN. Dept. of Mines, Canada Geol. Survey, *Summary Rept.* 1917, C, 14c-21c(1918).—The stratigraphy, structure, and economic geology of the region are described and analyses of coal, lignite and oil given. S. G. GORDON.

The Ohio shales of Southwestern Ontario. M. Y. WILLIAMS. Canada Dept. Mines, Geol. Survey, *Summary Rept.* 1917, E, 26c-28e(1918).—The shales are dark gray, black or brown, occurring just above the Hamilton formation. Proximate analyses and results of distn. tests are given. S. G. GORDON.

Surface deposits of Southeastern Saskatchewan. J. STANSFIELD. Canada Dept. Mines, Geol. Survey, *Summary Rept.* 1917, C, 41c-52c(1918).—The deposits and economic geology of the region are described and 12 analyses of water given. S. G. GORDON.

The Crawfordjohn essexite and associated rocks. ALEXANDER SCOTT. *Geol. Mag.* 2, 455-61, 513-9(1915).—The intrusion occurs on the west side of Craighead Hill, 2½ miles east of Crawfordjohn, in Ordovician grits and shales, folded and lying nearly vertical, and considerably metamorphosed by the intrusion. The essexite is a gray compact rock with numerous phenocrysts of augite, being, however, at the margin aphanitic (monchiquite). Microscopically the rock consists of olivine crystals, laths of feldspar, large augite phenocrysts, with ilmenite, apatite and a little biotite; the interstices are filled with nephelite and analcite. The contact effects are described in detail, and analyses of the rock are given. S. G. GORDON.

Tektites from British Borneo. F. P. MUELLER. *Geol. Mag.* 2, 206-11(1915).—Tektites were found in 1913 near Tutong Station, southwest of Brunei, apparently washed out of a white quartz sand deposit. The stones are dark greenish brown, with brilliant luster, triangular, egg-shaped, or spherical, weighing 0.5-11.72 g., and scored with fine marks. Microscopic examn. showed them to be pure glass; sp. gr. 2.457,  $H_6$ ,  $n_D = 1.5097$ . Analysis by Dr. Hinden gave:  $SiO_2$  70.90,  $Al_2O_3$  13.50,  $Fe_2O_3$  0.32,  $FeO$  5.47,  $CaO$  2.35,  $MgO$  2.45,  $Na_2O$  1.46,  $K_2O$  2.17,  $TiO_2$  (estd.) 1.00,  $MnO$  tr., sum 99.62%. S. G. GORDON.

The petrology of the Suffolk box-stones (Crag). P. G. H. BOSWELL. *Geol. Mag.* 2, 250-9(1915).—The box-stones are masses of hard, brown sandstone about the size of the fist, often well rounded, and frequently containing fossils, including wood, bone, teeth, and casts of mollusca. Microscopically the rock is a coarse sandstone made up of clear quartz grains in a brown matrix. Analysis showed 20.1% Ca phosphate. The following minerals were noted in the box-stones: magnetite, garnet, zircon, rutile, ilmenite, tourmaline, calcite, apatite, quartz, andalusite, staurolite, topaz, marcasite, actinolite, hornblende, epidote, muscovite, titanite, orthoclase, microcline, plagioclase, cyanite, limonite, glauconite, and opal. S. G. GORDON.

The genesis of chialstolite; and its supposed occurrence in association with a basic intrusion. ALFRED BRAMMALL. *Geol. Mag.* 2, 224-8(1915).—Chialstolite is described as occurring as embryonic microscopic aggregations in a shale altered by a basic sill intrusive at Marston Jabet, near Nuneaton. The production of the mineral depends upon maintaining a comparatively low temp. within a restricted range, and is effected by meteoric or juvenile waters. S. G. GORDON.

Possible harmonizing of the hydrous and anhydrous theories of volcanism. A. GUEBHARD. *Compt. rend.* 167, 955-8(1918).—A discussion. L. W. RIGGS.

A biochemical theory of the origin of indianaite. WILLIAM N. LOGAN. *Science* 44, 197(1919).—Indianaite (halloysite) occurs as a white porcelain-like mineral in

beds up to 11 feet thick in the Mississippian and Pennsylvanian rocks. The following biochem. theory is advanced to account for the deposits: shales containing pyrite are weathered and sulfuric acid is produced, which attacks the clay, forming Al sulfate. S bacteria absorb the sol. alum, rob it of its S, secreting Al in the form of a hydrated silicate, which by partial dehydration is rendered insol., becoming indianaite. Bacteria similar to *Beggiatoa alba* have been isolated, and their influence has been demonstrated in the lab.

S. G. GORDON.

**Elaboration of silica and calcium silicates by algae of the *Girvanella* group.** JACQUES DE LAPPARENT. *Compt. rend.* 167, 999-1001(1918).—It has previously been observed that crystals of albite may exist in the midst of granular limestone elaborated by the action of algae of the *Girvanella* group upon calcareous organisms in the rocks at the base of the upper Cretaceous of the western Pyrenees. Certain of these limestones when treated with HCl yield a large amt. of foraminifera which resist the action of the acid. Upon isolation it is seen that they have been entirely transformed to chalcedony. The elaboration of  $\text{SiO}_2$  and the transformation of calcareous into siliceous organisms, as well as the production of granular limestone is the work of *Girvanella*. In the Ca silicate the  $\text{SiO}_2$  is united to CaO in the proportion of a metasilicate and  $\text{Al}_2\text{O}_3$  adds itself to the Ca metasilicate mol. to mol. The sol. part of the limestone is 97.6%  $\text{CaCO}_3$  and 2.4 Al silicate yielding a formula  $\text{RO}_2\text{MO}$ , the  $\text{Al}_2\text{O}_3$  being computed partly as acid and partly as base.

L. W. RIGGS.

Tungsten, with special reference to the Black Hills of South Dakota (RUNNER, HARTMAN) 9.

## 9. METALLURGY AND METALLOGRAPHY.

WILLIAM BRADY, WILLIAM T. HALL.

**Mining and milling of lead and zinc ores in the Missouri-Kansas-Oklahoma zinc district.** C. A. WRIGHT. *Bur. Mines, Bull.* 154, 126 pp.(1918).—A detailed account, with illustrations, maps, flow sheets, drawings, and tables, of investigations made by the Bureau of the methods used in mining and milling. The conditions that affect the efficiency of the methods are discussed in some detail, together with the possibilities of making certain improvements that would effect a greater saving. The publication cannot be very well abstracted.

F. W. SMITHER.

**The Middlemarch mine and mill.** B. M. SNYDER. *Mining Sci. Press* 118, 181-2 (1919).—A description, with illustrations and flow sheet, of operations at the Middlemarch mine and mill near Pearce, Ariz. An ore averaging 2% Cu as chalcopyrite is coned. by straight flotation, using a mixt. of coal tar (80%), pine oil, and coal-tar creosote. Crushing is done by ball-mill, flotation by launder pneumatic and K and K machines. The recovery is over 90%.

F. W. SMITHER.

**Cheap leaching of gold-ore tailings.** ANON. *Eng. Mining J.* 107, 226(1919).—A description of a method (Australian patent N. 6516, of 1918) of cyaniding tailings in vats the sides of which are formed by the sepd. slime.

F. W. SMITHER.

**Review of the manganese situation.** C. M. WELD. *Bur. Mines War Minerals Investigations Ser.* 1918, No. 7, 12 pp.—Specifications governing the sale of metallurgical Mn ores are discussed, including the matter of premiums and penalties on silica and P in the ores, as adopted by the Ferro Alloys Committee of the Iron and Steel Inst., and effective in May, 1918. Statistics on imports and domestic production for the period 1913-18 are shown for Mn ores and alloys, as well as on the comparative prices for the period 1910-18. The threatened shortage of Mn of a number of months

ago has entirely disappeared, due to the powerful stimulus exerted on the industry by high prices and patriotic motives. In spite of reduced importations the country's stocks are steadily increasing.

A. L. FEILD.

Gold, silver, copper, lead and zinc in Utah in 1917. Mines report. V. C. HIEKES. U. S. Geol. Survey, *Mineral Resources of U. S., 1917*, Part I, 167-202 (preprint No. 12, published Feb. 8, 1919); cf. C. A. 12, 669.

E. H.

Occurrence, chemistry, metallurgy and uses of tungsten, with special reference to the Black Hills of South Dakota. J. J. RUNNER AND M. L. HARTMAN. S. Dakota School of Mines, *Bull.* 1918, No. 12, 236 pp.; cf. Hess, C. A. 11, 3211.—W deposits in Black Hills are confined to 3 areas: (1) vicinity of Harney Peak in pegmatitic granite and quartz veins, principally as wolframite; (2) Nigger Hill district in Pre-Cambrian rocks as wolframite, small amts. of scheelite, hubnerite and ferberite; (3) Lead-Deadwood district as wolframite and some hubnerite in Cambrian dolomite and basal quartzite locally known as Deadwood Formation. The last named are replacement deposits. Some wolframite is found in rhyolite porphyry, which is regarded as source. Until 1915 all Black Hills W ore was sold as hand-picked ore. The Homestake mill at Lead, which is in operation at present, began concg. ores 1915. Gold recovery pays for ore treatment. Other mills in operation in 1916 and 1917 are not now in operation. The chemistry, metallurgy and uses of W are discussed completely and authoritatively. Special attention is given the use of W in high-speed tool steel. An exhaustive bibliography of W is included.

BYRON H. SMITH.

The reduction of tungstic oxide. C. W. DAVIS. *J. Ind. Eng. Chem.* 11, 201-4 (1919).—An exptl. study reported in detail. Summary: "(1) The  $WO_3$  used for reduction must be pure, dry, and in a state of fine division. (2) When reduced with C, the  $WO_3$  should be thoroughly mixed with it. (3) At  $650^\circ$  to  $850^\circ$   $WO_3$  goes to a blue or purple oxide when heated with C; at  $900^\circ$  to  $1050^\circ$  a chocolate material is the result; and at temps. above  $1050^\circ$  the gray powdered metallic W results. (4) As the W is easily oxidized, the reduced material must be cooled in a reducing atm. (5) The ratio of  $WO_3$  to C varies from 10:1 to 10:1.6, depending on the process used, the temp. of reduction and the time involved. (6) Excess C can be partially removed by washing. (7) Fire-clay crucibles or Fe tubes give satisfactory reduction with a product of over 98% W. Under the conditions of the test some oxides resulted at portions nearest the crucible cover and tube ends. (8) Fire-clay is not attacked by the charge at the temp. used. The Fe tubes suffer considerable oxidation on the outside. (9) A continuous process could be arranged to get a W powder free from oxides. (10) The time of reduction of small samples at  $1100^\circ$  is less than 1 hr. (11) The temp. of reduction with H at ordinary pressures is much the same as with C. The product is over 98% W."

F. W. SMITHER.

Production of ferromanganese in blast furnaces. P. H. ROYSTER. *Bur. Mines War Mineral Investigations Ser.* 1918, No. 5, 31 pp.; cf. C. A. 12, 452.—A study of 11 blast furnaces making ferromanganese. Tables and charts of data are given. Fe-Mn furnaces operate at lower temps. than Fe furnaces. Gas analyses show that practically all the MnO is reduced "directly" by C, probably in the hearth. "Volatilization" loss of Mn is not affected by any change in furnace conditions. Slag loss of Mn is decreased by raising the blast temp., increasing the basicity of slag and charging more coke; it is increased by fast driving and carrying a greater "slag volume." A general equation is given for the % of Mn in slag as a function of these 5 quantities, by means of which the slag loss can be calcd. in advance from charge-sheet data. Five changes in practice

are recommended: (a) using better grade of coke, (b) better grade of stone, (c) less fuel, (d) running with a more basic slag, (e) driving faster. Special emphasis is laid on the desirability of low-SiO<sub>2</sub> stone. An estd. increase of \$20,000,000 in annual net profits of the 11 furnaces examd. would be brought about if the above changes were made. There is greater opportunity for improvement in selection of coke and stone than in furnace practice.

BYRON H. SMITH.

The application of pyrometers to core ovens. G. W. KELLER. *Foundry* 47, 72-4(1919).—The author points out how the demands of modern industry have developed refinements in core room and foundry practice.

F. W. SMITHER.

Carbon Steel Co. additions. ANON. *Iron Age* 103, 349(1919).—A brief description of a new forge building and of a 72-in. jobbing plate and sheet mill (in course of installation). Other improvements are touched upon.

F. W. SMITHER.

The Utah copper enterprise. IX. The smelting of the concentrate. T. A. RICKARD. *Mining Sci. Press* 117, 853-60(1918); cf. C. A. 13, 303.—The H<sub>2</sub>O content of 13.6% carried by the mixt. of table and flotation concentrates causes the smelter a great deal of trouble in sampling, handling, and roasting. Its treatment at the Garfield smelter is described. Nodulizing of the concentrates in rotary kilns is suggested. This is practiced at Braden, Chile, and has been experimented with at Chrome, N. J., and Princeton, B. C. A 100-ft. kiln would nodulize 100-125 tons in 24 hrs., at the same time accomplishing partial desulfurization. With oil as fuel the consumption was 6-7 gal. per ton of concentrate.

A. BUTTS.

The manufacture of copper driving bands. W. J. REARDON. *Metal Ind.* 17, 63-8(1919).—The manuf. of copper driving bands by the Ward process is discussed. A brief description of the Moseberg method is given.

E. S. WHITTIER.

Rust-proofing of iron and steel. ELMER S. WHITTIER. *Metal Ind.* 17, 79-82(1919).—The Parker rust-proofing process is described. The preliminary treatment of the metallic surfaces before processing is discussed.

**Tentative specifications for light aluminium casting alloys.** ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 497-501(1918). E. E. R.

**Tentative definitions and rules governing the preparation of micrographs of metals and alloys.** ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 716-21(1918).—In addition to specifying standard magnifications and suggesting suitable lenses, the method of measuring the grain size is described. E. E. R.

**Physical qualities of high-chrome steel.** L. R. SEIDELL AND G. J. HORVITZ. *Iron Age* 103, 291-4(1919).—Expts. show that an intimate relation exists between the amt. of double carbide in solid soln., the max. hardness and the magnitude of "red hardness." With few exceptions, the micro-constituents of this kind of steel are analogous to those of common steel. When quenched from 1380° all the carbide remains in solid soln., giving a uniform structure and max. hardness. Under these conditions the tensile strength and ductility are at a max. after suitable drawing operations. The effect of initial temp. on the position of the  $A_{r1}$  point is an indication of the amt. of carbides retained in solid soln. E. E. R.

**The structure and strength of overheated rivet steel.** S. H. GRAF. *Eng. News-Record* 82, 280-2(1919).—Rivet steel may contain from 0.05 to 0.25% C according to the strength required; the av. content is 0.12% C. To study the effects of over-heating, steels with 0.11% and with 0.23% C were used. The specimens were (a) held at 1200° for 10 min. and air-cooled, (b) over-heated in the forge until sparks began to come off and kept at this temp. for 2 min., (c) refined by heating above the upper limit of the critical range for 15 min. and air-cooling from 1115°. (d) Fresh pieces were subjected to treatment (b), reduced to half the original length and forged to about 0.25 in. sq. Photomicrographs were taken of the samples after each of the above treatments. Alternating impact tests showed that the over-heated specimens were very brittle and unreliable. Over-heating raises the yield point and reduces the ductility and "reduction of area." Heat treatment improves the material. E. E. R.

**Durability of high-speed steels.** R. A. POLIAKOFF. *Iron Age* 103, 295-6(1919).—The expts. described were made at Moscow for one of the largest Russian railroads. 9 brands of commercial high-speed steels were tested. The C content was very low for all the steels. According to Taylor, the best high-speed steels have between 0.50 and 0.68% C in order that the steel may be easily forgeable, not too brittle but sufficiently hard. In these steels, the C limit was still lower. All of the brands were low in Mn and did not contain over 0.15% Si, which indicates that Taylor's suggestions have been adopted. The S and P contents were low in all cases. The W content varied from 10.4 to 18.2%, none of the newer steels contained V, only one contained Mo, and 2 contained Ni. The steels were all sold at the same price but the durability varied from 21.5 min. to 2 hr. W. T. H.

**Effect of heat treatment on bronze.** F. F. HAUSEN AND O. A. KNIGHT. *Foundry* 47, 61-5(1919).—The effects of heat treatment on bronze containing 59% Cu, 39% Zn, 1.5% Fe and 0.5% Mn are shown by photomicrographs and by hardness values. The Brinell test verified the conclusion to be drawn from the microstructure, i. e., that the specimen quenched at 800° and drawn at 300° would be the hardest. Above 300°, the hardness gradually decreased with rise in drawing temp. W. T. H.

**Reducing the malleable iron annealing period.** A. E. WHITE AND R. S. ARCHER. *Foundry* 47, 61-5(1919).—In producing malleable Fe, practical men usually insist on a slow heating, a low annealing temp., and a very slow cooling. If, however, the annealing temp. is raised a little above the critical point and then kept at about 700° long enough to convert about 0.7% of combined C to graphitic C, considerable time can be saved and malleable Fe of good quality produced. Hard spots, such as are likely to result by segregation of Mn or S are avoided by this treatment. Cooling at the rate of 8.3° per hr. from the critical temp. down to 660° is a safe rate and at this temp. the furnace may be opened. The initial heating must not be too rapid. W. T. H.

**Comparison of the internal elastic equilibrium of alloys after quenching and after cold drawing.** A. PORTEVIN. *Compt. rend.* 167, 1033-5(1918).—The internal stresses produced by hardening have been compared with those produced by cold work. This paper is meant to serve as a warning against carrying this comparison too far. Brass with about 60% Cu was tested after quenching at 760° and after cold drawing. Plotting the internal stresses against the surface area of the specimens gave curves which were inversely proportional to one another. W. T. H.

**The alterability of aluminium.** Corrosion and disintegration JEAN ESCARD. *Rev. sci.* 56, 331-6(1918).—The action of acids, alkalies, and oxygen, the effect of cold work, and the action of saline solutions at different temps. are discussed in detail for commercial Al and in brief for important Al alloys. No new data are given. W. T. H.

**Ferrous alloys.** JEAN ESCARD. *Rev. gén. sci.* 29, 706-13(1918); cf. C. A. 13, 308.—The methods of manuf., uses, chem. compn. and important physical properties of Fe-V, Fe-Mo, Fe-Ti, Fe-W, Fe-Al, and Fe-Ni alloys are described. Fe-Ce, Fe-P, Fe-B, Fe-Ta, We-U, Fe-Si-Al, Fe-Si-Ni, Fe-Si-Mn, Fe-Si-Cr, Fe-Si-W, and Fe-Si-Ca-Al alloys are mentioned. W. T. H.

**The use of magnetic properties in inspecting iron and steel.** V. PREVER AND M. PREVER. *Ind. chim. min. met.* 5, 153-5, 179-82, 185-7(1918).—The decrease in magnetic permeability of steel with increase in hardness has been successfully used by Colonnetti and Pozzo in the inspection of projectiles. The apparatus used consists of a double coil, one coil being connected to a ballistic galvanometer and a continuous cur-

rent which may be reversed is passed through the other. The specimen is inserted in the center of the double coil. On reversing the current a deflection of the galvanometer is produced which depends on the permeability of the specimen. With specimens of uniform size and regular shapes such as billets, shells, etc., there is close agreement between Brinell hardness tests and the galvanometer readings. Attempts to apply this method of testing to small auto parts of irregular shapes made of Ni-Cr steel failed, there being in general no relation between the Brinell hardness and the deflections. The Brinell tests were confirmed by tension tests. The irregularities could not be explained on the basis of variation in compn. or weight. Pieces of the same form but of different alloy steels or heat treatment could be distinguished from each other, but not Ni-Cr steels of different C content.

J. S. LAIRD.

The crystal structure of gray tin. A. J. BIJL AND N. H. KOLKMEIJER. Utrecht. *Chem. Weekblad* 15, 1264(1918); cf. *C. A.* 12, 2533.—Gray Sn is cryst.; the crystals belong to the regular system, and the atoms are arranged in the same manner as the C atoms in diamond. The length of the lines of the elementary cube is  $6.46 \times 10^{-8}$  cm.; the interval between the atoms is  $2.80 \times 10^{-8}$  cm. The quadrivalency of this form is plainly evident, while in the tetragonal form 2 atoms are at a less interval from the central atom than the other 2, showing bivalency. According to later and more accurate measurements, the values  $5.85 \times 10^{-8}$  and 0.408, as mentioned in the previous paper (*l. c.*) should be  $5.84 \times 10^{-8}$  and 0.406, resp.

JULIAN F. SMITH.

Aluminum bronze alloy. ANON. *Metal Record & Electroplater* 4, 267-70(1918).—A brief illus. account of the golden Al-Cu alloy (about 91% Cu). It is used in ornamental architectural work, for cutlery, etc. The hard grade has a tensile strength of 75,000 lbs. per sq. in., after working the metal, 111,000; elastic limit 45,000 lbs. per sq. in., elongation, 1600%. The alloy can be forged, tempered, can be used for knife blades and takes a high polish. Compared to Cu it is very acid-resistant.

C. G. F.

The action of organic acids on metals. C. L. DE FOUW. Amsterdam. *Pharm. Weekblad* 55, 1497-9(1918).—To study the possible effects of organic acids upon the containers of canned goods, 0.1 and 0.01 *N* solns. of oxalic, tartaric, citric, malic, acetic and lactic acids were used. They all attack Sn rapidly in air, but scarcely at all *in vacuo* or in CO<sub>2</sub>. The effect is dependent on the concn. of acid. Neutral salts have little effect on the action, except that nitrates catalyze it markedly. All the acids oxidize more Sn than corresponds to the amt. of acid present; this is probably due to hydrolysis. In the main, insol. Sn(OH)<sub>2</sub> is formed. It is sol., however, in tartaric and oxalic acids. Some metastannic acid is formed also. The reactions with Zn are very similar; but oxalic acid has scarcely any action on Zn, and even inhibits the action of other acids. The amt. of corrosion is also dependent on the metal concn. Complex ions are formed; the Sn<sup>++++</sup> ions form complexes more readily than the Sn<sup>++</sup> ion. The series for the acids, in descending order, is: oxalic, citric, tartaric, lactic. No definite relation could be established between complex formation and rapidity of action.

---

**Concentrating ores.** E. EDGER and S. TUCKER and MINERALS SEPARATION, LTD. Brit. 121,303, Sep. 13, 1917. In an agitation froth process for the preferential sepn. of one metalliferous mineral from another in a mixt. containing them, *e. g.*, a mixed sulfide ore, the agents employed are a sol. soap and  $\text{Na}_2\text{SiO}_3$  in such proportions that a froth rich in one of the minerals is first obtained. After this froth has been sepd., the liquor may be dild. and re-agitated or aerated for the production of froth rich in another mineral. The ore is preferably treated in a freshly ground condition. Cf. 7,803, 1905, 2,359, 1909, 21,857, 1910 (*C. A.* 6, 1426), and 105,227.

**Ore concentration.** WM. O. ARZINGER. Can. 188,627, Feb. 11, 1919. Electrically conducting values are sepd. from associated gang by causing a fluid jet to impinge upon the surface of the contaminated liquid in the presence of air to entrain in and mix the air with the liquid while feeding the value of gang to the surface of the liquid. The jets of air produce a buoyant mass which is statically charged and which acts to bring the values quickly to the surface. Cf. *C. A.* 13, 114.

**Apparatus for ore concentration.** WM. O. ARZINGER. Can. 188,626, Feb. 11, 1919. In combination with the reservoir adapted to hold the contaminated liquid are means for causing a fluid jet to impinge on the surface of the liquid to entrain air therein and form buoyant vesicles and upwardly moving currents, means for feeding values of gang to the liquid and means for causing the currents to carry the values out of the reservoir.

**Concentrating ores by flotation.** R. GAHL. U. S. 1,290,166, Jan. 7. Ores which have generally been considered unsuitable for flotation sepn., such as sulfide or carbonate ores containing small percentages of Cu, are rendered more amenable to flotation sepn. by mixing with them Fe or steel in a finely divided form, *e. g.*, filings, before subjecting the ore to ordinary flotation treatment. Steel balls may be used for grinding the ore, thus incorporating the desired amt. of steel in finely divided form to facilitate the flotation. Addition of minute quantities of  $\text{PtCl}_4$  materially increases the amount of foam formed when air is blown through the flotation medium. Presence

of metallic Zn decreases the efficiency of the process. The Fe used may be recovered by magnetic sepn.

**Fluorinating device.** J. P. RUTH. Can. 188,640, Feb. 11, 1919. A gas diffusion device for use in flotation process comprizes a rotary head having a plurality of passages for gas extending outwardly to the periphery of the head and stationary hoods at the outer extremities of the passages.

**Treating oxide ores.** SELDEN IRWIN CLAWSON. Can. 188,548, Feb. 4, 1919. Oxide ores are fluxed in proper proportions with a halogen salt of the metalloid group, the base metal of which prefers O to Cl when in an oxidizing atm. where the desired metals are chloridized and the metalloid flux is oxidized, the metal chloride and metalloid oxides are then recovered and treated with a reducing agent to liberate the desired metal in metallic state and the metalloid oxides as chlorides.

**Treating aluminous ores.** H. A. RICHMOND. Can. 188,745, Feb. 18, 1919. Carbonaceous material and a sulfide are mixed with aluminous ore, the mixt. is heated electrically and the impurities are removed as gaseous sulfide. Elimination of the silica is thus satisfactorily obtained.

**Reducing ores.** J. M. LONGYEAR and J. T. JONES. U. S. 1,289,834, Dec. 31. Fe oxide ore or other ore to be reduced is placed in a shaft reducing furnace in which superposed sections of the charge of ore and fuel are supported at different levels and air is supplied in limited amounts through twyers at the different levels to effect deoxidizing without producing a molten bath. In the lower portion of the furnace a high-temp. metal-fixing zone is maintained near the bottom of the stack which serves to preheat, without attacking, fuel in the upper portion of the stack. U. S. 1,289,835 relates to a shaft furnace for similar operation.

**Vertical shaft furnace for reducing ores.** J. T. JONES. U. S. 1,289,800, Dec. 31. The furnace is especially adapted for the reduction of Fe ores and is provided with twyers at different levels for separately supplying air in limited amounts to ore and fuel charges supported at different portions of the shaft.

**Fume arresters for smelting plants.** ANTONIO FERRARI. Can. 188,805, Feb. 25, 1919. The smoke arrester consists of a horizontal condensing passage into which fumes pass from the furnace, a smoke stack to which one end of the passage is connected, a horizontal perforated pipe for spraying the interior of the horizontal passage and a vertical perforated pipe extending upwardly within the stack and arranged to drop a spray upon the fumes at and above the point where the fumes change their direction of movement from a horizontal to a vertical path.

**Extracting nickel from silicate ores.** H. W. C. ANNABLE. U. S. 1,289,072, Dec. 31. Garnierite ore is ground and then intimately mixed with Fe pyrites and NaCl,  $\text{Na}_2\text{CO}_3$ ,  $\text{Na}_2\text{SO}_4$ ,  $\text{K}_2\text{CO}_3$  or  $\text{K}_2\text{SO}_4$  and the mixt. is heated to  $650\text{--}800^\circ$  in contact with steam and with exclusion of air, to form NiS. The resulting product, containing FeS and NiS, is heated in air to a temp. sufficiently high to oxidize the sulfides to sulfates and to decompose the Fe sulfate without decomposing the Ni sulfate and the hot oxidized product is discharged into  $\text{H}_2\text{O}$  which is maintained at a temp. below  $30^\circ$  to dissolve the Ni sulfate. In case basic Ni sulfate has been formed, HCl is added to the  $\text{H}_2\text{O}$  to effect its soln. After sepn. of the Ni sulfate soln., the Ni may be recovered from it by pptn. with a carbonate or sulfide, *e. g.*, by addition of  $\text{CaCO}_3$  to the soln. and passing furnace gases from the roasting furnace directly into the soln. The pptd. salt of Ni is dried and heated in the atm. to form Ni oxide. If the mixt. of sulfides of Fe and Ni is heated and NaCl is then added to the product to be oxidized, a much lower yield of sol. Ni is obtained. Sea water may be used as a source of NaCl in the process.

**Ferromanganese.** J. T. JONES. U. S. 1,289,799, Dec. 31. Finely divided ore containing oxides of Fe and Mn is heated with an excess of finely divided coal, substantially out of contact with air, the product is crushed, Fe is magnetically sep'd., Mn is obtained from the residue by a gravity sepn. and selected proportions of Fe and Mn are then fused together to produce a ferro-Mn of the desired compn. Low-grade Mn ore of the Cuyuna Range in Minn. may be used in the process. A ferro-Mn low in P is produced.

**Smelting lead.** T. W. CAVERS. Can. 188,629, Feb. 11, 1919. In the blast-furnace smelting of Pb ores the charge is heated essentially by blasting in carbonaceous fuel with air into the lower part of the furnace above the normal slag level.

**Briquetting cement copper.** C. A. HALL. U. S. 1,290,024, Dec. 31. Cement Cu in association with waste liquor, such as the mixt. which is obtained by the treatment of cinders formed in roasting cupreous pyrites in the manuf. of  $H_2SO_4$ , which usually contains at least 25% of moisture, is pressed into bricks under a pressure of 250 lbs. per sq. in. and the bricks are then dried to prep. them for smelting to recover the Cu.

**Disintegrating metals to dust-like form.** E. J. HALL. U. S. 1,290,181, Jan. 7. In the production of metallic powder or dust, the metal under treatment, *e. g.*, Zn, is melted, mixed with an alloy of Al with the metal to be disintegrated, and the mixt. is then atomized in molten condition and allowed to solidify to powder. The presence of the Al renders the molten metal more fluid, thus facilitating atomization, and also serves to protect the other readily oxidizable metal (*e. g.*, Zn) from oxidation during the atomization.

**Melting metal scrap.** D. EPPELSHEIMER. U. S. 1,290,143, Jan. 7. A mixt. of scrap Fe or steel or other fragmentary metal to be melted down in an open-hearth furnace is formed into compressed blocks together with an admixture of lumps of coke. When this material is subjected to the melting operation in an open-hearth furnace, a uniform admixture and interaction of the metal and C is obtained, without undesirable segregation and floating of C masses. The compression of the mixt. is restricted so as not to destroy its porosity nor prevent access of air and gases to the coke in the mass.

**Steel.** H. C. DICKSON and J. B. NICKLIN. Brit. 121,311, Nov. 10, 1917. A steel, particularly for the production of bright drawn rods or bars for airplane or motor parts and other purposes, contains 0.1–0.3% of C, 0.08–0.25% of Si, 0.4–1% of Mn, 0.05–0.2% of V, and 0.05–0.25% of Cr. S and P are as low as possible.

**Annealing low-carbon steel.** J. H. BENNETT. U. S. 1,289,092, Dec. 31. In annealing low-C steel, the metal is heated, preferably to redness, and then cooled and softened by the application of  $H_2O$  to which 1.5% of soap has been added. The addition of the soap effects a cooling of the metal without rendering it hard or brittle.

**Castings of cerium and other rare earth metals.** A. HIRSCH and M. HIRSCH. U. S. 1,290,010, Dec. 31. In casting Ce or other rare earth metals or their alloys, the metal is introduced into a mold, which may be formed of Fe, at a temp. sufficiently close to the congealing point of the rare earth metal that danger of inflammation of metal is avoided. The mold is constructed so that its heat-absorbing capacity is not sufficient to cause material imperfections in the castings due to unequal cooling. Ce castings may be thus formed which are adapted for use as sparking devices.

**Castings of cerium or other rare earth metals.** A. HIRSCH and M. HIRSCH. U. S. 1,290,011, Dec. 31. In prepg. Ce or other rare earth metal or their alloys for casting, the metal is melted beneath a layer of molten  $BaCl_2$  to protect it from oxidation or ignition.

**White gold alloy.** DAVID BELAIS. Can. 188,628, Feb. 11, 1919. Fine Au 75 to 85%; pure Ni, 10 to 18%; and pure Zn 2 to 9%, are fused and thoroughly mixed together to produce a substitute for Pt, especially in the jewelry trade.

**Coating iron or steel to prevent rusting.** W. H. ALLEN. U. S. 1,290,476, Jan. 7. A soln. for "rust-proofing" Fe or steel is formed by dissolving 1% of ferric phosphate in a 10% soln. of  $H_2PO_4$  in  $H_2O$ .

**Solution for rust-proofing metals and for nut-locking.** C. D. MATTHEWS. U. S. 1,289,855, Dec. 31. A soln. for treating Fe or similar metals, intended for locking nuts on bolts or for forming an oxidized coating on Fe or steel, is formed of a satd. soln. of NaCl in HOAc mixed with an equal amt. of  $HNO_3$ .

## 10. ORGANIC CHEMISTRY.

CHAS. A. ROUILLER.

**Stability of cyclic systems.** J. BÖSEKEN with MISS M. DE GROOT AND W. VAN LOOKEREN CAMPAGNE C. JZN. Delft. *Rec. trav. chim.* 37, 255-65(1918).—In a previous paper (*C. A.* 8, 2345) B. and Sillevs showed that cyclohexene is metastable and when passed over finely divided Ni at  $180^\circ$  in a stream of  $CO_2$  reacts thus:  $3C_6H_{10} \rightarrow 2C_6H_{12} + C_6H_6$ . The heat of combustion of cyclohexene is 892.6 Cal., that of a mixt. of  $1/3$   $C_6H_6$  and  $2/3$  cyclohexane is 884.1 Cal. There is thus a difference of 8.5 Cal. Cyclohexene (a) left in contact with Pd in a sealed tube lost the odor of (a) and no longer decolorized Br  $H_2O$ . These expts. were continued with the mixt. of cyclohexadienes (b) obtained by boiling dibromo-1,2-cyclohexane with an excess of quinoline. The reaction  $3C_6H_8 \rightarrow C_6H_{12} + 2C_6H_6$  takes place more easily than that with (a). The heat of combustion of  $C_6H_8$  is approx. 847.5 Cal., for a mixt. of  $1/3$   $C_6H_6$  +  $2/3$   $C_6H_{12}$  832.5 Cal.; or a difference of 15 Cal. (b) passed over finely divided Ni at  $180^\circ$  in  $CO_2$  loses its disagreeable odor and acquires that of  $C_6H_6$ , the d. and refraction are raised and the product is indifferent to Br. The results demonstrate the instability of dihydrobenzene. 42 g. dibromo-1,2-cyclohexane were heated under reduced pressure with 92 g. freshly distilled quinoline. The reaction begins at  $160^\circ$  and is energetic at  $180^\circ$ . The product (b),  $b_{760}$   $79.5-80^\circ$ , has an odor resembling that of isoprene. Only about 0.5 of the calcd. amt. of Br is absorbed. Further work will be required to explain this. The app. for passing (b) over finely divided Ni was that used by B. and v. Senden (*C. A.* 7, 1702). The product had lost about 99% of its capacity to combine with Br, had the odor of  $C_6H_6$  and gave  $PhNO_2$  with  $HNO_3$ . In the presence of excess H,  $C_6H_8$ , cyclohexene and cyclohexadiene easily give  $C_6H_{12}$  in the presence of Ni at  $180^\circ$  or of Pt at room temp. Under ordinary conditions the satd. ring with 6 C atoms is stable, although that of methylcyclopentane may be a little more so. Zelinskii (*C. A.* 6, 598) and Willstätter found the pentatomic C ring very stable. At  $180^\circ$  with excess H and Ni the tetratomic C ring is easily opened; with Pt this occurs easily at room temp. (*C. A.* 11, 34). Expt. on pinane, obtained by reducing pinene, having 2 satd. rings showed that the ring with 4 C atoms is not reduced under these conditions. Pinane may be regarded as a cyclobutane containing a 4- and a 6-atomic C ring. Cyclobutane-1,1-dicarboxylic acid (c), cyclobutanecarboxylic acid (d), its amide (e), cyclobutylamine (f), and cyclobutanol (g), were all prepd. and tested and found to be stable toward H in the presence of Pt at  $25^\circ$ . (c) was prepd. by the method of Perkin. (d) was obtained by distn. of (c). The chloride of (d) was obtained with  $PCl_5$  and converted into (e) by adding it drop by drop to satd.  $NH_3$  at  $0^\circ$ , and extg. the aq. soln. with  $Et_2O$ . (e) was converted into (f) by using NaOCl by Weerman's method (*C. A.* 12, 1462). The hydrochloride of (f) treated with a slight excess of  $AgNO_3$  in aq. soln. gave (g). Full exptl. details are given. E. J. WITZEMANN.

**Phenylurethans of terpenic alcohols and of phenols.**—F. WEGHUIZEN. Weltevreden, Java. *Rec. trav. chim.* 37, 266–9 (1918).—W. has prepd. several urethans of terpenic alcs. and phenols in a simple manner by dissolving the requisite amts. of the compds. in a mixt. of hydrocarbons (b. 170–200°) composed mostly of decane and undecane, and boiling the soln. This solvent has the several advantages: (1) the presence of H<sub>2</sub>O is excluded so that the formation of diphenylurea need not be feared; (2) the reagents are easily sol.; (3) the urethans are difficultly sol. and sep. as beautiful crystals on cooling. 0.500 g. *o*-cresol + 0.600 g. PhNCO in 6 cc. of the solvent gave after boiling 15 mins. and cooling nearly the calcd. amt. of the urethan, m. 141°. The *m*-deriv. (m. 121–2°) and *p*-deriv. (m. 112–3°) were similarly obtained. The phenylurethans of thymol, menthol and borneol, m. 106–7°, 111–2° and 137–8°, resp., were similarly obtained. For eugenol best results were obtained with benzine (b. 80–100°) in a closed flask at room temp. in a desiccator. If no excess of PhNCO is used camphor may be sepd. from borneol when the two are mixed in equal proportions. With geraniol and linalool the diphenylurea was obtained indicating that probably some H<sub>2</sub>O is split off during the reaction.

E. J. WITZEMANN.

**The action of hydrazine hydrate on cyanotetrazole.** J. LIFSCHITZ AND W. F. DONATH. Univ. Zurich. *Rec. trav. chim.* 37, 270–93 (1918).—L. showed (C. A. 9, 1614; 10, 1527) that cyanotetrazole and an EtOH soln. of NH<sub>2</sub>NH<sub>2</sub>·H<sub>2</sub>O react at the temp. of the H<sub>2</sub>O bath to give a yellow compd. (C<sub>2</sub>N<sub>4</sub>H<sub>4</sub>)<sub>x</sub> which was regarded as a deriv. of pentazole. Curtius, Darapsky and Müller (C. A. 10, 63) regarded it as the hydrazine salt of ditetrazyldihydropentazine (a) with which opinion L. and D. now agree, (a) was obtained from cyanotetrazole (b) prepd. (Oliveri-Mandalà and Passalacqua, *Gazz. chim. ital.* 41, 465, 1; C. A. 6, 625) by introducing (CN)<sub>2</sub> into aq. solns. of HN<sub>3</sub>. In their expts. in the prepn. of large amts. of (b) L. and D. made various observations. (b) was obtained purer the more dil. the HN<sub>3</sub> soln. was, but the yield falls with the diln. Theoretically a larger formation of bistetrazole and tetrazolecarboxamide occurs in more concd. HN<sub>3</sub> solns. The (b) formed at first will be exposed to the excess of azoimide and the reaction HN<sub>4</sub>CCN + HN<sub>3</sub> → HN<sub>4</sub>CCN<sub>2</sub>H will take place as well as HN<sub>4</sub>CCN + H<sub>2</sub>O → HN<sub>4</sub>CCONH<sub>2</sub>. An aq. soln. of HN<sub>3</sub> satd. with (CN)<sub>2</sub> and exposed to the light from a quartz Hg-vapor lamp gives a smaller yield of (b) than when it was exposed to diffuse sunlight which seems to favor the reaction. When the EtOH soln. of (b) is treated with NH<sub>2</sub>NH<sub>2</sub>·H<sub>2</sub>O a white turbidity is formed, which varies with the purity of the (b) used, and ppts. finally as 2 easily separable compds. One part is easily sol. in H<sub>2</sub>O and is mainly the hydrazine salt of bistetrazole (cf. also C., D. and M.). The insol. part is sol. in acids and is thought to be the hydrazine salt of tetrazolecarbohydrazidine, N<sub>2</sub>H<sub>4</sub>·HN<sub>4</sub>C·C(NH<sub>2</sub>):NNH<sub>2</sub> or N<sub>2</sub>H<sub>4</sub>·HN<sub>4</sub>CC(:NH)-NHNH<sub>2</sub>. This result is supported not only by the analyses of the salt, the free compd. after removal of N<sub>2</sub>H<sub>4</sub>, and of the Ag salt but also by the following reactions: (1) HNO<sub>3</sub> reacts with it to give bistetrazole which was identified by its compn. and that of its Ag salt: HN<sub>4</sub>C(NH<sub>2</sub>):NNH<sub>2</sub> + HNO<sub>3</sub> → HN<sub>4</sub>CCN<sub>2</sub>H + 2H<sub>2</sub>O. (2) With aldehydes like BzH, O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>CHO and anisaldehyde it gives condensation products HN<sub>4</sub>CC(:NH)NHN:CHR or HN<sub>4</sub>CC(:NNH<sub>2</sub>)N:CHR. (3) If this white substance is boiled with excess N<sub>2</sub>H<sub>4</sub>·H<sub>2</sub>O in EtOH yellow hydrotetrazine (c) is formed. The formation of (c) is interpreted from the beginning as follows: RCN + NH<sub>2</sub>NH<sub>2</sub> → RCC(:NH)NHNH<sub>2</sub>; RC(:NH)NHNH<sub>2</sub> + H<sub>2</sub>O → RCONHNH<sub>2</sub>. 2 mols. of the latter may condense to give aminotriazoles H<sub>2</sub>NN.(R)C:N.N:CR or hydrotetrazines

RC:N.NH.C(R):N.NH with the loss of 2 H<sub>2</sub>O mols. The interpretation of C., D.

and M. (l. c.) is opposed because dihydrotetrazine was not obtained on boiling the N<sub>2</sub>H<sub>4</sub> salt of the hydrazidine or the hydrazidine itself with an excess of tetrazolenitrile.

The (a) was more fully characterized by a series of salts and by the di-Et ether and by its transformation into the corresponding tetrazine. The latter furnishes 2 series of differently colored salts. The orange-red Na and K salts are easily sepd. into a yellow and a red-violet form. With the Ba salt the sepn. was incomplete while with the other salts and the di-Et ether only the red-violet form was obtained. Further study will show whether this is a case of true isomerism like

(b) was prepd. by satg. a cold aq. soln. of  $\text{HN}_3$  with  $(\text{CN})_2$ . This was placed in an ice box 24 hrs. and then concd. at  $55^\circ$  to a small vol.: a red color due to decompn. of cyanotetrazole should not appear. The concd. soln. solidifies *in vacuo* over  $\text{P}_2\text{O}_5$ . 2 g. (b) in 25 cc. EtOH were cooled and treated with 2.5 g.  $\text{NH}_2\text{NH}_2 \cdot \text{H}_2\text{O}$ . The white ppt. and its examn. were described above. The exptl. details are all given. 10 g. (a) were dissolved in 100 cc. warm  $\text{H}_2\text{O}$  and while boiling 50 cc. dil.  $\text{HCl}$  (1:1) were added. The free dihydrotetrazine (c) is pptd. quant.; yellow, compact, with 2 mols.  $\text{H}_2\text{O}$  of crystn., sol. in  $\text{H}_2\text{O}$ , EtOH,  $\text{Et}_2\text{O}$ ,  $\text{Me}_2\text{CO}$ ,  $\text{C}_6\text{H}_6$  and ligroin. With  $\text{EtNO}_2$  (c) gives a red color and after some days is completely converted into ditetrazyltetrazine (d). 2 g. (a) in 50 cc. hot water were treated with a concd. soln. of  $\text{KCl}$  and a nearly quant. ppt. of the yellow *potassium salt* of ditetrazyl dihydrotetrazine was obtained. The *barium salt* was obtained similarly. 2 g. (a) in 50 cc.  $\text{H}_2\text{O}$  were treated in the cold with  $\text{AgNO}_3$  soln. and then heated to boiling, by which the pptd. *silver salt* was changed from dark yellow to light yellow. The Ag salt was treated with EtI and 20 cc. abs. EtOH and boiled 5 hrs. on a  $\text{H}_2\text{O}$ -bath. On cooling AgI sepd. and yellow plates of the *ethyl ether*, on evapg. the EtOH *in vacuo*; heated to  $120^\circ$  in the air it is oxidized to the red tetrazine ether, described below. Small amts. of ditetrazyl dihydrotetrazine (e) suspended in an excess of aq. soln. of  $\text{NaNO}_2$  and treated with concd.  $\text{HCl}$  gives a moderate yield of (d). 10 g. (e) were suspended in 150 cc. MeOH, treated with 10 cc.  $\text{EtNO}_2$  and kept on ice overnight. The addition of  $\text{EtNO}_2$  at 24-hr. intervals was repeated several times. This was the best method of prep. (d). (d) was also obtained by triturating the yellow Na salt of (c) with cold dil.  $\text{H}_2\text{SO}_4$  (1:3). The constitution

less sol. in  $\text{Et}_2\text{O}$  and when heated quickly it detonates. On heating (d) in EtOH soln. with a little mineral acid the red color disappears at once, gas is evolved and (c) seps. as beautiful, yellow crystals. Even on spontaneous evapn. of solns. of (d) auto-decompn. takes place and a brown, viscous product is formed, so that absence of acid and evapn. *in vacuo* are desirable. By the action of excess  $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{O}$  or  $\text{NH}_3$  in EtOH (d) is converted into (c). 2 g. (e) suspended in 10 cc.  $\text{H}_2\text{O}$  were treated with just enough concd.  $\text{Na}_2\text{CO}_3$  to dissolve the (a) with warming. After filtering a concd. soln. of  $\text{NaNO}_2$  was added and finally the mixt. was acidified with glacial AcOH. On standing in the cold the orange-red *sodium salt* of (d) sepd. In 80% EtOH this salt is only partly sol.: the residue is yellow and the red-violet soln. seps. a violet salt. When the yellow salt is dissolved in  $\text{H}_2\text{O}$  and pptd. with EtOH or  $\text{Et}_2\text{O}$  the violet salt is pptd. Free (d) treated in concd. EtOH soln. with the calcd. amt. of  $\text{NaOEt}$  gives the same Na salt. 1 g. (e) in 5 cc.  $\text{H}_2\text{O}$  was treated with the calcd. amt. of  $\text{KNO}_2$  in a little  $\text{H}_2\text{O}$  and then acidified with glacial AcOH. The orange-red *potassium salt* of (d) seps. at once. It can be sepd. into an orange and a violet fraction as with the Na salt. 0.5 g. of the Na salt of (d) dissolved in 20 cc.  $\text{H}_2\text{O}$  was treated while boiling with a soln. of  $\text{BaCl}_2$ : orange microcrystals of the *barium salt* of (d) sepd. at once. The treat-

ment with  $H_2O$  did not cause a good sepn. of 2 forms. It explodes with extreme violence when heated. 1 g. of the Na salt in 50 cc. boiling  $H_2O$  is treated drop by drop with  $AgNO_3$  and after a long time the dark violet *silver salt* of (d) is pptd.; it explodes at  $150^\circ$ . It may also be prepd. from (a) with  $AgNO_3$  and  $HNO_3$ . The  $HNO_3$  oxidizes the hydrotetrazine. The ether of (d) could not be obtained from EtI and the Na salt but it was obtained from  $Me_2SO_4$  and the Na salt. 1.5 g. of the Ag salt boiled with EtI for 0.5 hr. and then treated with 30 cc. abs. EtOH gave on cooling and evap. after filtering off AgI beautiful, red crystals of the *ethyl ether* of (d). On passing  $NH_3$  gas through an ice-cooled soln. of (d) the *ammonium salt* of (d) seps. as a red-violet microcryst. powder; the salt m.  $275^\circ$ . 1.5 g. (d) in 20 cc. EtOH were treated carefully with a dil. EtOH soln. of  $N_2H_4 \cdot H_2O$ . Addition was stopped before the soln. was completely decolorized. The red-violet *hydrazine salt* of (d), is decolorized at  $190^\circ$  and m.  $210^\circ$ .

E. J. WITZEMANN.

**The action of fumaryl chloride on fumaric acid.** G. C. A. VAN DORP AND P. J. MONTAGNE. Leyden. *Rec. trav. chim.* 37, 294-302(1918).—W. A. and G. C. A. van Dorp (*Rec. trav. chim.* 25, 96(1906)) treated fumaric acid with fumaryl chloride at  $175^\circ$  and sepd. maleicanhydride from the product by boiling with  $C_6H_6$ . Pure fumaric anhydride was not sepd. By boiling with  $PhNH_2$  fumaranilic acid was obtained which indicates that fumaric acid was present as the anhydride, polymeric anhydride or mixed chloride anhydride. This work has been repeated and extended. A mixt. of 4 g. fumaric acid and 6 g. fumaryl chloride were heated in an oil bath  $160-2^\circ$  until 1.33 g. HCl (about 0.5 of the calcd. amt.) had been evolved. After cooling  $C_6H_6$  was added and rapidly heated to boiling. The next day the product was filtered and washed with  $C_6H_6$ : product A. The residue was boiled with 1 l.  $C_6H_6$  and filtered hot: product B. The residue was product C. A was treated with 20 cc.  $PhNH_2$  in 100 cc.  $C_6H_6$  and boiled 0.5 hr. and filtered the next day. The ppt. was washed with cold  $H_2O$  to remove  $PhNH_2 \cdot HCl$ . The part insol. in alkali was recrystd. from AcOH. 3.6 g. fumardianilide (a), m.  $309^\circ$ . The alk. soln. acidified with HCl gave 3.7 g. maleinanilic acid (b), m.  $185^\circ$ . 1.8 fumaric acid was recovered from the alc. soln. in which (b) was recrystd. (b) is formed from maleic anhydride by a mol. transformation of 1 mol. fumaryl chloride acting on 2 mols. fumaric acid with the liberation of 2 mols. HCl. (a) is probably mainly formed from unattacked fumaryl chloride. B treated with  $PhNH_2$  as with A gave finally 0.20 g. (a) and 0.25 g. (b). These 2 products may have arisen from a product formed thus:  $ClOC.(CH)_2.COC(=O)H + HOOC.(CH)_2.COOH \rightarrow ClOC.(CH)_2.C(=O).O.CO.(CH)_2.COOH$  (I) + HCl and (I) +  $ClOC.(CH)_2.COC(=O)H \rightarrow ClOC.(CH)_2.C(=O).O.CO.(CH)_2.C(=O).O.CO.(CH)_2.COC(=O)H$  (II) + HCl. (II) may react with 4 mols.  $PhNH_2$  to give 2 mols. of (b) and 1 mol. of (a), which was about the ratio found with B. C treated with  $PhNH_2$  as with B gave finally 0.20 g. (a), 0.22 g. (b), 0.70 g. impure fumaranilic acid and 0.57 g. impure fumaric acid. (II) could not have been present in C but it might have contained (I) and the  $PhNH_2$  derivs. found could have been formed from it. Other details not represented here are given.

E. J. WITZEMANN.

**Tetrahydronaphthalene series.** ARTHUR G. GREEN AND FREDERICK M. ROWE. *J. Chem. Soc.* 113, 955-73(1919).—The derivs. of ar-tetrahydro- $\alpha$ -naphthylamine, ar-tetrahydro- $\alpha$ -naphthol and  $\alpha$ -chloro-ar-tetrahydronaphthalene corresponding to the more important dye intermediates in the  $C_6H_5$  and  $C_{10}H_7$  series have been made in order to det. whether they might be of practical use in the prepn. of new dyes. In general, they are of no comm. value. A review of the literature on the properties of ar-tetrahydro- $\alpha$ -naphthylamine (A) shows that in certain reactions it is like an amine of the  $C_6H_5$  series, in other reactions like an amine of the  $C_{10}H_7$  series. The azo dyes derived from (A) approximate more closely in shade the dyes from benzenoid amines

rather than those from  $\alpha\text{-C}_{10}\text{H}_7\text{NH}_2$ . The hydrochloride of (A) is obtained in 70% yields when  $\alpha\text{-C}_{10}\text{H}_7\text{NH}_2$  is treated with boiling AmOH and Na, then poured into  $\text{H}_2\text{O}$ , the AmOH layer sepd. and acidified with HCl, the alc. steam distd. and the aq. soln. of the hydrochloride, after filtration, evapd. to dryness. Traces of ac-tetrahydro- $\alpha$ -naphthylamine are also formed. Neither EtOH nor BuOH can be used. As BuOH even under pressure or with a catalyzer such as Na-Hg,  $\text{Hg}_2\text{Cl}_2$ , Ni or dextrose gives no results, the reduction is probably connected with the oxidation of the AmOH. Tetrahydroaceto- $\alpha$ -naphthalide (B) (*J. Chem. Soc.* 85, 737) treated with  $\text{HNO}_3$  (1 mol.) and 100%  $\text{H}_2\text{SO}_4$  at  $-10^\circ$  gives 4-nitro-ar-tetrahydroaceto- $\alpha$ -naphthalide (C), colorless needles from dil. alc. or  $\text{H}_2\text{O}$ , m.  $178^\circ$ . By reduction of (C) with Fe and HOAc, 1-acetyl-ar-tetrahydro-4-naphthylenediamine (D) results, colorless plates or needles from  $\text{Et}_2\text{O}$ , m.  $291^\circ$ , which readily diazotizes and couples with amines and phenols. (C) with alc. NaOH gives 4-nitro-ar-tetrahydro- $\alpha$ -naphthylamine (E), yellow needles from dil. alc., m.  $116^\circ$ . (E) with alc. HCl forms a hydrochloride, colorless needles decompd. by  $\text{H}_2\text{O}$ ; (E), in  $\text{C}_6\text{H}_6$  treated with alc. KOH, on evapn. gives the orange-red K salt  $\text{NH}\cdot\text{C}_{10}\text{H}_{10}\cdot\text{NO}_2\cdot\text{K}$ . (E) is readily diazotized and coupled to form azo dyes similar in appearance and shade to those obtained from *p*-nitroaniline. (E) with  $\text{SnCl}_2$  gives ar-tetrahydro-1,4-naphthylenediamine (F), isolated as the diacetate (G), colorless needles from HOAc, m.  $291^\circ$ . (F) in HCl treated with  $\text{CrO}_3$ , then extd. with  $\text{Et}_2\text{O}$ , gives tetrahydro- $\alpha$ -naphthoquinone (H), yellow needles from petroleum, m.  $55^\circ$  (*Ber.* 23, 1132). (B) with  $\text{HNO}_3$  (2 mol.) and 100%  $\text{H}_2\text{SO}_4$  at  $-10^\circ$  gives 2,4-dinitro-tetrahydroaceto- $\alpha$ -naphthalide (I), colorless needles from alc., m.  $202^\circ$ . Further nitration of (C) also gives (I). Upon triturating (I) with a little  $\text{H}_2\text{O}$ , then dissolving in  $\text{H}_2\text{SO}_4$  and warming, 2,4-dinitro-ar-tetrahydro- $\alpha$ -naphthylamine (J) forms, yellow needles from alc., m.  $181^\circ$ . The K salt of (J) is a bluish green powder formed by evapn. of a mixt. of a  $\text{C}_6\text{H}_6$  soln. of (J) and alc. KOH. When ar-tetrahydro- $\alpha$ -naphthol (K) (*Ber.* 21, 1892) is treated with cold concd.  $\text{H}_2\text{SO}_4$  for 2 days ar-tetrahydro- $\alpha$ -naphthol-sulfonic acid (L) is obtained and isolated as the Na salt, colorless efflorescent needles. Upon dissolving (K) in cold  $\text{H}_2\text{SO}_4$ , allowing to remain 2 days, then dilg. and adding dil.  $\text{HNO}_3$  (1 mol.), 2-nitro-ar-tetrahydro- $\alpha$ -naphthol-4-sulfonic acid (M) is obtained, yellow needles, m.  $182^\circ$ , crystd. by dissolving in  $\text{H}_2\text{O}$  and adding HCl. Dil.  $\text{H}_2\text{SO}_4$  hydrolyzes (M) to 2-nitro-ar-tetrahydro- $\alpha$ -naphthol (N), yellow needles from  $\text{Et}_2\text{O}$ , m.  $56^\circ$ . (N) forms with NaOH a Na salt, orange plates from  $\text{H}_2\text{O}$ , and also couples with diazonium compds. to form azo dyes. If (K) is dissolved in NaOH and treated with  $\text{NaNO}_2$  (2 mol.), then acidified with  $\text{H}_2\text{SO}_4$ , 4-nitro-ar-tetrahydro- $\alpha$ -naphthol (O) forms, yellow needles from dil. alc., m.  $163^\circ$ . (O) differs from (N) in that it does not couple with diazonium compds. 2,4-Dinitro-ar-tetrahydro- $\alpha$ -naphthol (P) forms yellow prisms from  $\text{Et}_2\text{O}$ , m.  $105^\circ$ . It is made by nitration of (K) with  $\text{H}_2\text{SO}_4$  and 2 mol. dil.  $\text{HNO}_3$ , first cold, then warmed to  $50^\circ$ ; it is also produced by further nitration of (N) or (O) or of diazotetrahydronaphthalene-4-sulfonic acid. Sulfur dyes formed from (P) are valueless. Diazotization of (A) and treatment with HCl and CuCl give  $\alpha$ -chlorotetrahydronaphthalene (Q), colorless liquid,  $b_{748}^{250^\circ}$ , and tetrahydronaphthalene as by-product. Cold concd.  $\text{H}_2\text{SO}_4$  and  $\text{HNO}_3$  (2 mols.) with (Q) give 1-chloro-2,4-dinitro-ar-tetrahydronaphthalene, (R), colorless needles from petroleum, m.  $68^\circ$ . The halogen in (R) is not active as it is in 2,4-( $\text{O}_2\text{N}$ ) $_2\text{C}_6\text{H}_2\text{Cl}$ . An alc. soln. of (A), 2,4-( $\text{O}_2\text{N}$ ) $_2\text{C}_6\text{H}_2\text{Cl}$  and a little NaOAc when refluxed gives 2,4-dinitrophenyl-ar-tetrahydro- $\alpha$ -naphthylamine red leaflets from alc., m.  $134^\circ$ . 2,4-( $\text{O}_2\text{N}$ ) $_2\text{C}_6\text{H}_2\text{Cl}$  also condenses with ac-tetrahydro- $\alpha$ -naphthylamine, to give 2,4-dinitrophenyl-ac-tetrahydro- $\alpha$ -naphthylamine, yellow plates from alc., m.  $121^\circ$ . ROGER ADAMS.

The *N*-butylarylamines. I. The action of *n*-butyl chloride on *o*- and *p*-toluidine. JOSEPH REILLY AND WILFRED J. HICKINBOTTOM. *J. Chem. Soc.* 113, 974-85(1919).

—BuCl (A) reacts with *p*-toluidine to give sec. and tert. arylamines; with *o*-toluidine, however, to give *o*-MeC<sub>6</sub>H<sub>4</sub>NHBu exclusively, although methylation under the same conditions gives a di-Me deriv. The properties of the various derivs. of mono-butyl-*o*- and *p*-toluidines are compared. BuOH and *p*-MeC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>·HCl give at 140° a sec. amine but at a higher temp. complex primary and sec. amines, the structures of which were not detd. BuOH and PhNH<sub>2</sub>·HCl at 200° gives chiefly PhNHBu (*J. Chem. Soc.* 113, 102) but at 240–80° chiefly *p*-BuC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub> and higher butylated products. Crude *p*-MeC<sub>6</sub>H<sub>4</sub>NHBu (B) b. 250–60° and crude *p*-MeC<sub>6</sub>H<sub>4</sub>NBu<sub>2</sub> (C) b. above 260°, are obtained by heating *p*-toluidine (1 mol.) and BuCl (2.5 mols.) 60–80 hrs., distg. the excess of (A), making alk. with aq. NaOH, extg. with Et<sub>2</sub>O, pptg. unchanged *p*-toluidine with ZnCl<sub>2</sub> soln. and fractionating the products. Crude (B) with HCl and NaNO<sub>2</sub> gives *p*-tolylbutylnitrosoamine (D), pale yellow oil. Crude (D) with concd. HCl and Zn dust on a H<sub>2</sub>O bath gives *butyl-p-toluidine* (E), *b*<sub>710</sub> 264–5°; *hydrochloride*, colorless needles, m. 150–1°, from (E) in C<sub>6</sub>H<sub>6</sub> and gaseous HCl. *Oxalate*, white plates, m. 185°; *picrate*, red oil. Ac<sub>2</sub>O and (E) give *acetobutyl-p-toluidide* (F), pale yellow oil, *b*<sub>710</sub> 294–5°. *Benzobutyl-p-toluidide* is a yellow oil, b. above 380°. Pure (C), *b*<sub>714</sub> 282–4°, can be obtained by fractionation of the crude material, or from the crude mixt. of (B) and (C) by treating with HNO<sub>3</sub>, extg. with Et<sub>2</sub>O the (D) which seps. and making alk. *Ferrocyanide*, white powder; *picrate*, yellow crystals from Et<sub>2</sub>O, m. 109–10°. By the action of BuCl on *o*-toluidine in the same way as it was allowed to react with *p*-toluidine, *butyl-o-toluidine* (G) is produced, colorless oil, *b*<sub>711</sub> 258–60°, but no dibutyl-*o*-toluidine is formed. (G) gives an *acetyl derivative* (H), colorless oil, forms with HNO<sub>3</sub> *o*-tolylbutylnitrosoamine (I), a yellow oil. (I) in Et<sub>2</sub>O with alc. HCl gives *5-nitrosobutyl-o-toluidine hydrochloride* (J), green-yellow powder, decomp. 136° (J) with dil. NH<sub>4</sub>OH gives *5-nitrosobutyl-o-toluidine*, blue needles from Et<sub>2</sub>O-petr. ether, m. 50°. (J) forms with CuCl<sub>2</sub> a *cuprichloride*, green crystals; (J) decomp. with alkali to give 5-nitroso-*o*-cresol and BuNH<sub>2</sub>. BuOH (1.3 mol.) with PhNH<sub>2</sub>·HCl (1 mol.) is heated at 240° for 7–8 hrs., made alk., the fraction, b. 255–65°, changed to an insol. sulfate and then again made alk., which gives pure *p*-aminobutylbenzene (K), *b*<sub>710</sub> 258–60°. Pure (B) treated with diazotized sulfanilic acid gives a mixt. of diazoamine and azo compds. Pure *sodium 4-methyl-N-butyl-diazoaminobenzene-4'-sulfonate* (L) can be isolated by carrying out the diazotization in alc., adding satd. NaOAc, evapg. on the H<sub>2</sub>O bath, converting into the free base with H<sub>2</sub>SO<sub>4</sub>, extg. with Et<sub>2</sub>O and finally treating in alc. with alc. KOH. It is a red powder. II. Nitration of mono- and di-*n*-butyl-*p*-toluidines. *Ibid* 985–95. —*p*-MeC<sub>6</sub>H<sub>4</sub>NHBu (A) in concd. H<sub>2</sub>SO<sub>4</sub> with HNO<sub>3</sub> (1 mol.) at a low temp. gives *2-nitrobutyl-p-toluidine sulfate* (B), white plates from abs. alc., m. 152°. Both HCl and HBr salts of (B) are white solids. The free base is a red oil and gives with Ac<sub>2</sub>O *2-nitroacetobutyl-p-toluidide* (C), yellow needles, m. 48°. (B) in glacial AcOH with NaNO<sub>2</sub> forms *2-nitro-p-tolylbutylnitrosoamine* (D), a pale yellow oil. By the action of HNO<sub>3</sub> in AcOH on *p*-MeC<sub>6</sub>H<sub>4</sub>NBuAc, *3-nitroacetobutyl-p-toluidide* (E) is produced, yellow crystals from alc., m. 68°. (E) is hydrolyzed by dil. H<sub>2</sub>SO<sub>4</sub> to *3-nitrobutyl-p-toluidine* (F), a red oil. (A) in AcOH with HNO<sub>3</sub> (d. 1.5) gives *3,5-dinitrobutyl-p-toluidine* (G), orange needles from MeOH, m. 53°. (G) with Ac<sub>2</sub>O forms *3,5-dinitroacetobutyl-p-toluidide* (H), pale yellow needles from petr. ether and acetone, m. 55°. (G) with HNO<sub>3</sub> in AcOH forms *3,5-dinitro-p-tolylbutylnitrosoamine* (I), yellow plates from MeOH, m. 56°. (I) is also obtained by very vigorous nitration of (A) or by nitrating at a low temp. *p*-MeC<sub>6</sub>H<sub>4</sub>N(NO)Bu (J) (see preceding abstract). If (J) is nitrated at a higher temp. or with HNO<sub>3</sub> (d. 1.5), *3,5-dinitro-p-tolylbutylnitrosoamine* (K) forms, yellow needles from 80% alc., m. 95°. The free base of (B) with HNO<sub>3</sub> (d. 1.5) gives *2,3,5-trinitro-p-tolylbutylnitrosoamine* (L), white needles, m. 87°.

(B) with  $\text{HNO}_3$  (d. 1.4) and  $\text{H}_2\text{SO}_4$  gives 2,3,5-trinitro-*p*-tolylbutyl-nitrosoamine (M), yellow crystals from dil. alc., m.  $80.5^\circ$ .  $p\text{-MeC}_6\text{H}_4\text{NBu}_2$  on nitration in glacial AcOH gives (I), showing that one Bu group has split off during the reaction. In concd.  $\text{H}_2\text{SO}_4$ ,  $\text{HNO}_3$  (1 mol.) converts  $p\text{-MeC}_6\text{H}_4\text{NBu}_2$  into 2-nitrodibutyl-*p*-toluidine (N), a red oil; its hydrochloride forms white crystals. Further nitration of (N) produces (M), thus showing the position of the  $\text{NO}_2$  group in (N) to be ortho to the Me group.

ROGER ADAMS.

Phenylsuccinic acid series. VII. The action of alcohols and amines on  $\gamma$ -diphenylsuccinic anhydride. HENRY WREN AND HOWELL WILLIAMS. Municipal Tech. Inst., Belfast. *J. Chem. Soc.* 113, 832-40(1918).—This investigation was undertaken to ascertain whether derivs. of mesodiphenylsuccinic acid are produced during the reaction of alcs. or amines with  $\gamma$ -diphenylsuccinic anhydride (A). The action of (A) on Me and Et alcs., on  $\text{PhNH}_2$  and *p*-toluidine were therefore studied. In the case of EtOH the main product formed was the monoethyl ester of  $\gamma$ -diphenylsuccinic acid and also a small quantity of Et mesodiphenylsuccinate. With MeOH Me  $\gamma$ -diphenylsuccinate was the only product obtained.  $\text{PhNH}_2$  yielded  $\gamma$ -diphenylsuccin-anilic acid only. The latter compd. was converted into diphenylsuccin-anil either by means of EtOH-HCl or heat. *p*-Toluidine, in  $\text{C}_6\text{H}_6$  soln. reacted very readily with (A) and  $\gamma$ -diphenylsuccino-*p*-toluidic acid, m.  $194-5^\circ$ , was the main product of the reaction. However, a small quantity of another compd. m.  $206^\circ$  (decompn.), was also obtained, which the author supposed to be the meso deriv.

MAX PHILLIPS.

Synthesis of ketones of the thiophene series. V. THOMAS AND V. COUDERC. *Bull. soc. chim.* 23, 288-91(1918).—T. had previously (cf. *Bull. soc. chim.* [4] 5, 730) shown that thienyl magnesium iodide (A) behaves in many reactions like  $\text{PhMgI}$ . In continuing this phase of the work, the author found that nitrites of certain aliphatic and aromatic acids react with (A), yielding ketones. Thus EtCN yields ethyl thienyl ketone,  $\text{C}_6\text{H}_5\text{COC}_2\text{H}_5\text{S}$ ,  $b_{25}$  128-9; PhCN yields phenyl thienyl ketone colorless needles, m.  $55^\circ$ , oxime m.  $80^\circ$ .  $\alpha$ - and  $\beta$ -Naphthyl thienyl ketone,  $b_{25}$  187-8 $^\circ$  and m.  $87^\circ$ , resp., were similarly obtained, using the corresponding nitriles. Dithienyl ketone was obtained through the action of ClCN and (A), colorless needles, m.  $87-8^\circ$ . M. P.

A new method of synthesis of acetylaminophenol ethers. R. KITAMURA. Tokyo. *Kwagaku Kwaishi* (*J. Tokyo Chem. Soc.*) 39, 1121-30(1918); *J. Pharm. Soc. Japan* 1918, No. 442, 971.—Phenacetin and allied substances are usually prepd. by the action of acids on the aminophenol ethers. K.'s method consists in allowing acid amides to react with halogen-substituted phenol ethers in the presence of Cu as in the condensation of  $\text{ClC}_6\text{H}_4\text{CO}_2\text{H}$  and  $\text{PhNH}_2$  proposed by Ullmann. K. prepd. phenacetin, metacetin, *p*-benzoylphenacetin and acetanilide from *p*-chloro- or bromophenol ether, *p*-bromoanisidine, *p*-bromophenetole and PhBr with  $\text{AcNH}_2$  and  $\text{BzNH}_2$ . Cu powder,  $\text{CuCl}_2$ ,  $\text{Cu}_2\text{Cl}_2$ ,  $\text{CuBr}_2$ ,  $\text{Cu}_2\text{Br}_2$ ,  $\text{CuSO}_4$ ,  $\text{ZnCl}_2$ ,  $\text{ZnSO}_4$  can be used as catalyst instead of mol. Cu.

S. KOMATSU.

The coloring matter in *Lithospermum erythrorhizon*. C. KURODA. Tokyo. *Kwagaku Kwaishi* (*J. Tokyo Chem. Soc.*) 39, 1051-1115(1918).—Shikon means purple root; it is the root of *Lithospermum erythrorhizon*, which was formerly used in Japan for dyeing a purple color. The coloring matter found in the root bark in the form of an Ac compd. was first studied by Kuhara (*J. Chem. Soc.* 35, 22-5(1879)) who ascribed to it the formula  $\text{C}_{20}\text{H}_{16}\text{O}_{10}$ . Kuroda, however, has isolated the substance in cryst. form of reddish brown color from its cold  $\text{C}_6\text{H}_6$  ext., has proved it has the formula  $\text{C}_{20}\text{H}_{16}\text{O}_8$  by its analysis and mol. wt. detn. and named it shikonine. Shikonine is best represented by Formula I; the evidence in support of this view is as follows: (1). It contains three HO groups since it yields  $\text{C}_{18}\text{H}_{14}\text{O}_8\text{Ac}_3$ , yellow needles, m.  $113^\circ$ ,  $\text{C}_{18}\text{H}_{14}\text{O}_8\text{Bz}_3$ , yellow crystals, m.  $168^\circ$ ,  $\text{C}_{18}\text{H}_{14}\text{O}_8\text{Cu}$  and  $\text{C}_{18}\text{H}_{14}\text{O}_8\text{Na}_3$ , and also a penta-Ac compd.,

m. 90° in the presence of Zn dust. (2). By dry distn., shikonine is transformed into  $\alpha$ -methylquinazarin (II), reddish brown needles, m. 232°; di-Ac compd.  $C_{14}H_8O_4Ac_2$ , m. 217°, which was identified with the substance synthesized from  $\alpha$ -methylphthalic anhydride and dimethylquinol by Lagodziuski's method (*Ber.* 28, 116(1895)). (3). (I) and (II) yield by Zn dust distn.  $\alpha$ - and  $\beta$ -methylantracene. By oxidation with

alk.  $KMnO_4$ , (I) yields malonic, fumaric and succinic acids and (II)  $\alpha$ -methylphthalic acid, resp. (4). (I) and (II) resemble in their absorption spectra and behavior on reduction naphthazarin and alizarin, resp. (5). Shikonine yields a monoxime, m. 163° and its Ac compd. by the action of  $O_3$  is decompd. into  $Me_2CO$  and 1,4-dihydroxyphthalic acid, m. 223°.

S. KOMATSU.

**Cinchona alkaloids. I. Cupreine, hydrocupreine and their methyl and ethyl ethers.** G. GIEBMSA AND J. HALBERKANN. *Inst. Schiffs- u. Tropenkrankh., Hamburg. Ber.* 51, 1825-33(1918).—Cupreine (a), obtained from the crude basic sulfate by removing accompanying alkaloids in alk. soln. by means of  $Et_4O$ , converting into the neutral sulfate, then into the hydrochloride and decompd. with  $NH_4OH$ , seps. from dil. alc. in prismatic tablets without  $H_2O$  of crystn., m. 201-2°, from  $Et_2O$  in druses of prismatic needles or tablets, m. 187°, become devitrified when covered with abs. alc., m. 202° after long drying at 125°,  $\alpha_D^{20}$  -174.4° (EtOH),  $\alpha_D^{23}$  -175.7° (MeOH), gives with Cl and Br  $H_2O$  only a faint yellow color gradually becoming greener and developing a blue fluorescence. Basic sulfate, needles without  $H_2O$  of crystn. from hot MeOH or AmOH, sol. in boiling  $H_2O$  with yellow color, m. 257° (decompn.). No salt with 6 mols.  $H_2O$ , as described by Hesse (*Ann.* 230, 59) and by Oudemann (*Rec. trav. chim.* 8, 147(1889)), could be obtained. Neutral sulfate, from  $H_2O$  in large, somewhat yellowish, prismatic tablets with 2 mols.  $H_2O$ , 1 of which is quickly lost at 100° or in 24 hrs. over  $H_2SO_4$ , becoming devitrified and rapidly reabsorbing the  $H_2O$  in the air. The 2nd mol. is completely lost only at 130-40°, the crystals crumbling to a S-yellow powder. A 1% soln. gives with  $FeCl_3$  a brown-red color with a violet cast,  $\alpha_D^{22}$  -197.9° ( $H_2O$ ). (a) is readily reduced to hydrocupreine (b) in the presence of 1% Pd pptd. on  $CaCO_3$  or purified infusorial earth, the reduction of 1 g. (a) with 2 g. catalyzer in 20 cc. alc. being complete in 20 min. at room temp. and atm. pressure. The reduction of (a)-HCl can also be effected with Kelber's 10% Ni catalyzer on infusorial earth (*C. A.* 10, 897), 1 g. (a) in 50 cc.  $H_2O$  with 5 g. catalyst requiring 30 min. (b) seps. from dil. alc. in needles, m. 204° (Hesse, *Ann.* 241, 281, and Pum, *Monatsh.* 16, 68, give 170°),  $\alpha_D^{20}$  -154.8° (alc.), shows no fluorescence in  $HNO_3$ , behaves like (a) towards  $NH_4OH$  and Cl or Br  $H_2O$ . Basic sulfate, long, fine needles. Neutral sulfate, faintly yellow octahedrons from  $H_2O$ , long, prismatic needles from aq.  $Me_2CO$ , both with 4  $H_2O$ , which is quickly lost over  $H_2SO_4$ , sol. in hot  $H_2O$  with yellow color; anhydrous, it m. 203° and takes up 1 mol.  $H_2O$  in the air. The (b) obtained as above and various com. samples, which were naturally prepd. from hydroquinine, all instantly decolorized acid  $KMnO_4$ ; H.'s statement that (b) is very stable towards  $KMnO_4$  is therefore erroneous. Methylcupreine (quinine), from (a) with alk.  $Me_2SO_4$  in MeOH or with  $CH_2N_2$  in AmOH, was identified through the basic sulfate which loses all of its  $H_2O$ , though slowly towards the last, at 120°, and reabsorbs 2 mols. in the air. Methylhydrocupreine, obtained from the above ether by catalytic reduction, or from (b) and

$\text{CH}_3\text{N}_3$ , analyzed as the sulfate which after 24 hrs. in the air contains 6 mols.  $\text{H}_2\text{O}$ ; the dehydrated salt reabsorbs 4 mols. in 24-48 hrs. Ethylcupreine from the Na salt of (a) and  $\text{Et}_2\text{SO}_4$ , pptd. by  $\text{NH}_4\text{OH}$  with 1 mol.  $\text{H}_2\text{O}$ , obtained pure by fractional pptn. from  $\text{Et}_2\text{O}$  with petr. ether, m.  $165-6^\circ$ ,  $\alpha_D^{20} -158.9^\circ$  (alc.); basic sulfate, fine, felted, flat, prismatic needles with 1  $\text{H}_2\text{O}$  which is very quickly reabsorbed after drying; neutral sulfate, prisms with 7 mols.  $\text{H}_2\text{O}$ ; anhydrous, it softens  $160^\circ$ , m.  $163-4^\circ$ , absorbs 2 mols.  $\text{H}_2\text{O}$  in the air. Ethylhydrocupreine, obtained by reduction of ethylcupreine or ethylation of (b), pptd. by  $\text{NH}_4\text{OH}$  in flocks with 1  $\text{H}_2\text{O}$ , sinters  $122^\circ$ , m.  $130^\circ$ ,  $\alpha_D^{20} -144.3^\circ$  (alc.); basic hydrochloride, identical with the com. "optochin," basic sulfate, long, prismatic needles with 4  $\text{H}_2\text{O}$ , m.  $235^\circ$  (anhydrous), reabsorbs 1-2 mols.  $\text{H}_2\text{O}$ , depending on the humidity, forms a blue-green to blue soln. in boiling  $\text{H}_2\text{O}$ ; neutral sulfate, large prisms with 7  $\text{H}_2\text{O}$ , quickly weathering. C. A. R.

**Synthesis of curcumin.** V. LAMPE. *Ber.* 51, 1347-55(1918); cf. C. A. 7, 3333.—Ethyl  $\alpha$ -carbomethoxyferuloylacetate (a), 3,4-MeO(MeO<sub>2</sub>CO) $\text{C}_6\text{H}_3\text{CH}:\text{CH}\cdot\text{COCHAcCO}_2\text{Et}$ , faintly yellow needles from alc., m.  $91-3^\circ$ , is obtained by adding to 2.4 g.  $\text{AcCH}_2\text{CO}_2\text{Et}$  and 1.25 g. powdered  $\text{NaOEt}$  which have been allowed to stand a long time in 50 cc.  $\text{Et}_2\text{O}$  in a freezing mixt. a suspension of 5 g. carbomethoxyferuloyl chloride in 50 cc.  $\text{Et}_2\text{O}$ , heating 2 hrs. on the  $\text{H}_2\text{O}$  bath, dissolving the  $\text{NaCl}$  formed in a little  $\text{H}_2\text{O}$  and evapg. the  $\text{Et}_2\text{O}$  layer. It dissolves in concd.  $\text{H}_2\text{SO}_4$  with yellow color and gives a yellow color with alc.  $\text{FeCl}_3$ . Shaken in  $\text{Et}_2\text{O}$  with 1%  $\text{NaOH}$  (a) quickly forms a red soln. from which  $\text{CO}_2$  ppts. the *q-hydroxy compound*, canary-yellow prismatic needles from alc., m.  $116-8^\circ$ , is colored red by concd.  $\text{H}_2\text{SO}_4$  and forms an orange soln. In the prepn. of (a) is also formed a by-product, carbomethoxyferulic anhydride,  $[\text{MeO}(\text{MeO}_2\text{CO})\text{C}_6\text{H}_3\text{CH}:\text{CHCO}]_2\text{O}$ , leaflets from alc., m.  $142-4^\circ$ . In the condensation of  $\text{PhCH}:\text{CHCOCl}$  with  $\text{AcCH}_2\text{CO}_2\text{Et}$  there is likewise formed as by-product cinnamic anhydride, prisms from alc., m.  $138^\circ$ . (a) on sapon. and simultaneous elimination of  $\text{CO}_2$  gives in good yield carbomethoxyferuloylacetone (b), faintly yellow, prismatic needles from alc., m.  $111-3^\circ$ , colored orange by concd.  $\text{H}_2\text{SO}_4$  and forming a yellow soln. with greenish cast; dil. alkalies split off the  $\text{MeO}_2\text{CO}$  group,  $\text{CO}_2$  pptg. the *hydroxy compound*, prisms from ligroin, m.  $143-5^\circ$ , colored red by concd.  $\text{H}_2\text{SO}_4$  and giving an orange soln., darkened by alc.  $\text{FeCl}_3$ . When 2 g. (b) in 15 cc. anisole allowed to stand 1 day at room temp. with 0.15 g. Na dust is treated with a still warm soln. of 1.85 g. carbomethoxyferuloyl chloride in 20 cc. anisole, allowed to stand 24 hrs., treated with a little acidified ( $\text{HCl}$ )  $\text{H}_2\text{O}$  and freed from anisole with steam there remains a heavy, dark red oil solidifying after a time to a cake probably consisting of dicarbomethoxydiferuloylacetone; 2 g. of this is boiled 1 hr. with 25 cc.  $\text{AcOH}$  and 15 cc.  $\text{H}_2\text{O}$  and on long standing the crimson soln. deposits 0.3 g. of dicarbomethoxydiferuloylmethane (c), obtained after repeated, very careful recrystn. from  $\text{C}_6\text{H}_6$  in large, faintly orange prisms, m.  $170-2^\circ$ , colored orange-red by  $\text{H}_2\text{SO}_4$  and giving a soln. of the same color and with faint red fluorescence. The faintly greenish fluorescent alc. soln. becomes dirty brown on addition of  $\text{FeCl}_3$  while basic Pb acetate or  $\text{Cu}(\text{OAc})_2$  produces no color or ppt. A comparison of (c) with dicarbomethoxycurcumin (C. A. 4, 2831) showed that the latter is a mixt. of isomers, careful crystn. from  $\text{C}_6\text{H}_6$  raising the m. p. from  $150^\circ$  to  $170-2^\circ$  and yielding a product identical with (c). When 0.5 g. (c) moistened with 5 cc.  $\text{Me}_2\text{CO}$  is treated in a H atm. with 3 cc. of 2 N  $\text{KOH}$ , warmed 1 hr. at  $50^\circ$ , dild. with 100 cc.  $\text{H}_2\text{O}$ , pptd. with  $\text{CO}_2$  and, after a time, with 60 cc. of 1%  $(\text{CO}_2\text{H})_2$ , filtered and recrystd. twice from  $\text{C}_6\text{H}_6$  and then repeatedly from  $\text{MeOH}$  there are obtained prisms, m.  $180-3^\circ$ , of *diferuloylmethane*, identical with natural curcumin, the constitution of which is thereby established. CHAS. A. ROUILLER.

**Synthesis of *p,p'*-dihydroxy- and *p*-hydroxydicinnamylmethane.** V. LAMPE AND M. GODLEWSKA. *Ber.* 51, 1355-60(1918); cf. preceding abstr.—Ethyl  $\alpha$ -*p*-carbometh-

*oxycinnamylacetacetate* (a),  $\text{MeO}_2\text{COC}_6\text{H}_4\text{CH:CHCOCHAcCO}_2\text{Et}$ , from  $p\text{-MeO}_2\text{COC}_6\text{H}_4\text{CH:CHCOCl}$ ,  $\text{AcCH}_2\text{CO}_2\text{Et}$  and  $\text{NaOEt}$  in  $\text{Et}_2\text{O}$ , yellowish prisms from alc., m.  $94-6^\circ$ , sol. in  $\text{H}_2\text{SO}_4$  with greenish yellow color, gives a dark red color with  $\text{FeCl}_3$ ; there is also formed some *p*-*carbomethoxycinnamic anhydride*, white aggregates from  $\text{PhMe}$ , m.  $168-70^\circ$ . Hydrolysis and elimination of  $\text{CO}_2$  from (a) give *p*-*carbomethoxycinnamylacetone*, faintly yellow leaflets from alc., m.  $111-3^\circ$ , sol. in  $\text{H}_2\text{SO}_4$  with greenish yellow color, gives a red-brown color with alc.  $\text{FeCl}_3$ ; shaken in  $\text{Et}_2\text{O}$  with dil. alkali it gives *p*-*hydroxycinnamylacetone* (b), yellow leaflets from dil. alc., m.  $144-6^\circ$ , colored red by  $\text{H}_2\text{SO}_4$  and forming a dark red soln. With  $\text{NH}_2\text{OH.HCl}$  in boiling alc. (b) gives *3-carbomethoxystyryl-5-methyl- or 5-carbomethoxystyryl-3-methylisoxazole*, leaflets from alc., m.  $122-4^\circ$ . *p,p'*-*Dicarbomethoxydicinnamylmethane*, from (b),  $p\text{-MeO}_2\text{COC}_6\text{H}_4\text{CH:CHCOCl}$  and Na in anisole, canary-yellow aggregates from ligroin- $\text{C}_6\text{H}_6$ , m.  $162-6^\circ$ , colored red by  $\text{H}_2\text{SO}_4$  and forming a soln. with intense yellow fluorescence, gives a brown color with alc.  $\text{FeCl}_3$ . With  $\text{NH}_2\text{OH.HCl}$  in alc. it gives *3,5-di[carbomethoxystyryl]isoxazole*, white aggregates from alc., m.  $178-80^\circ$ , while shaking in  $\text{Et}_2\text{O}$  with 1% NaOH produces *p,p'*-*dihydroxydicinnamylmethane*, faintly orange needles from  $\text{C}_6\text{H}_6$ , m.  $218-20^\circ$  (decompn.), sol. in alc. with dark red color and greenish fluorescence, gives a dark brown color with  $\text{FeCl}_3$ , sol. in  $\text{H}_2\text{SO}_4$  with crimson color and faint yellow fluorescence; a boiling aq. suspension imparts to unmordanted cotton a canary-yellow color not fast to soap; paper impregnated with an alc. soln. gives with  $\text{H}_2\text{BO}_3$  a faint orange color turned black by alkalies and re-established by acids. *p*-*Carbomethoxydicinnamylmethane*, from  $\text{PhCH:CHCOCH}_2\text{Ac}$  and  $p\text{-MeO}_2\text{COC}_6\text{H}_4\text{CH:CHCOCl}$ , yellow needles from ligroin, m.  $114-6^\circ$ , sol. in  $\text{H}_2\text{SO}_4$  with orange-red color and golden yellow fluorescence, gives a dark brown color with alc.  $\text{FeCl}_3$ . *p*-*Hydroxydicinnamylmethane*, faintly orange prismatic needles from  $\text{C}_6\text{H}_6$ -ligroin, m.  $190-2^\circ$ , sol. in  $\text{H}_2\text{SO}_4$  with crimson color and golden yellow fluorescence, gives a dark brown color with  $\text{FeCl}_3$  and with  $\text{Cu}(\text{OAc})_2$  a brown color rapidly changing to greenish; it dyes unmordanted cotton faintly lemon-yellow; paper impregnated with it is almost unchanged by  $\text{H}_2\text{BO}_3$  and alkalies produce a dirty violet spot.

CHAS. A. ROUILLER.

**Cinchona alkaloids. XX. Building up of cinchonatoxines.** PAUL RABE AND KARL KINDLER. Chem. Staatslab., Hamburg. Ber. 51, 1360-5(1918); cf. C. A. 12, 2565.—*N-Benzoylhomocincholoipon ethyl ester* (I), from 0.1 mol. benzoyldihydrocinchotoxine Me sulfomethylate (Kaufmann, C. A. 11, 963) in 40 parts  $\text{H}_2\text{O}$  treated with 0.4 mol.  $\text{KMnO}_4$  in 1.5 l.  $\text{H}_2\text{O}$ , filtered, acidified with  $\text{HCl}$ , extd. with much  $\text{Et}_2\text{O}$ , the ext. concd. to  $1/3$  its vol., washed 3 times with  $\text{H}_2\text{O}$ , dried with  $\text{Na}_2\text{SO}_4$ , evapd. and esterified with 4% alc.  $\text{HCl}$ , is a reddish yellow oil with greenish fluorescence,  $b_D^{25} 256^\circ$ ; this is hydrolyzed more quickly and with better yield by dil.  $\text{HCl}$  than by  $\text{Ba}(\text{OH})_2$  (with subsequent esterification), as done by K., to the homocincholoipon ester, an oil with blue fluorescence,  $b_D^{14} 140^\circ$ . Equimol. proportions of (I) and Et cinchoninate

(I)

(II)

heated in  $\text{C}_6\text{H}_6$  with  $\text{NaOEt}$  15 hrs. gave 40% of the  $\beta$ -ketonic ester (II) as a thick reddish oil, which, boiled 3 hrs. with 16%  $\text{HCl}$ , exactly neutralized with  $\text{NaOH}$ , freed from  $\text{BzOH}$  and unchanged (II) by exhaustive extn. with  $\text{Et}_2\text{O}$ , then treated with excess of alkali and extd. with  $\text{Et}_2\text{O}$ , yielded dihydrocinchotoxine (dihydrocinchonicine) (a), identical with the product obtained by rearrangement of dihydrocinchonine under the influence of  $\text{AcOH}$ ; with 1 mol.  $\text{PhNHNH}_2$  and 2 mols. picric acid in alc. containing a little  $\text{AcOH}$  it gives the intensely red *dihydrocinchotoxine phenylhydrazones dipicrate*,

m.  $215^{\circ}$  (decompn.); it was also converted into the *C*-bromohydrocinchotoxine *dihydrobromide*, which with dil. soda and  $\text{Et}_2\text{O}$  yielded dihydrocinchoninone, m.  $138^{\circ}$ ,  $[\alpha]_D^{18} 74.41^{\circ}$  after 1 hr.,  $76.45^{\circ}$  after 8 days (*c* 2.446 in alc.). CHAS. A. ROUILLER.

Action of phosphorus pentachloride on formylphenylacetic ester. WILHELM WISLICENUS AND ERNST A. BILHUBER. Univ. Tübingen. *Ber.* 51, 1366-71 (1918).—Unlike formyl- or hydroxymethylenecamphor (*a*), which with  $\text{PCl}_5$  yielded directly a mono-Cl compd. in which Cl replaces an OH group (Bishop, Claissen and Sinclair, *Ann.* 281, 316 (1894)), a reaction from which B., C. and S. conclude that (*a*) contains a HO and not a true aldehyde group, formylphenylacetic esters first give a di-Cl compd.,  $\text{CHCl}_2\text{CHPhCO}_2\text{R}$ , which easily loses HCl, forming the unsatd. mono-Cl deriv., and probably the same thing happens in the case of (*a*). Thus, when 20 g. of the liquid  $\alpha$ -Et formylphenylacetate (*b*) is slowly treated with 22 g.  $\text{PCl}_5$ , first in ice and finally on the  $\text{H}_2\text{O}$  bath, freed from  $\text{POCl}_3$  at  $125^{\circ}$  and fractionated *in vacuo* there is obtained an oil (*c*) of sharp odor,  $b_{18} 121-5^{\circ}$ , with 31.7% Cl (calcd. for ethyl  $\beta, \beta$ -dichloro- $\alpha$ -phenylpropionate, 28.7%); when this is treated with steam, very little distills over and most of it dissolves in the hot liquid; on cooling  $\beta$ -chloro- $\alpha$ -phenylacrylic (chlorotropaic) acid (*d*) seps. in long, silky needles, m.  $119-20^{\circ}$  (yield, 1.1 g. from 5 g. (*b*)); ethyl ester,  $b_{11} 133^{\circ}$ . Ethyl  $\beta, \beta$ -dihydroxy- $\alpha$ -phenylpropionate, from the crude (*c*) and 2 mols. NaOEt in alc. on the  $\text{H}_2\text{O}$  bath, yellow oil,  $b_{20} 166-8^{\circ}$ ; it is obtained in better yield (68%) by boiling 6.4 g. (*b*) with 6 cc. alc., 5.1 g.  $\text{HC}(\text{OEt})_3$  and 0.1 g.  $\text{NH}_4\text{Cl}$  15 min.; warmed with a little dil. HCl and alc., it regenerates (*b*), while 1.33 g. boiled a long time in alc. with 0.12 g. Na and a few drops of  $\text{H}_2\text{O}$  gives 0.9 g. of the free acid, tablets from  $\text{C}_6\text{H}_6$ , does not decolorize  $\text{KMnO}_4$  or Br, softens  $132^{\circ}$ , m.  $139^{\circ}$  (loss of  $\text{CO}_2$ ); alc. is also lost, with formation of  $\text{PhCH:CHOEt}$ ,  $b_{700} 213-5^{\circ}$  (slight decompn.), immediately decolorizes  $\text{KMnO}_4$  in aq.  $\text{Me}_2\text{CO}$  and Br. Methyl  $\beta, \beta$ -dichloro- $\alpha$ -phenylpropionate, obtained in 6 g. yield from 9 g. of  $\alpha$ -Me formylphenylacetate and 11 g.  $\text{PCl}_5$ ,  $b_{28} 137-41^{\circ}$ , quickly becomes turbid and deposits crystals; this decompn. is complete after 0.5 hr. boiling with 5 parts  $\text{H}_2\text{O}$ , the product being (*d*). Methyl  $\beta, \beta$ -dimethoxy- $\alpha$ -phenylpropionate, m.  $46-7^{\circ}$ ,  $b_{13} 135-42^{\circ}$ . CHAS. A. ROUILLER.

Mechanism of the assimilation process. K. SCHAUM. Giessen. *Ber.* 51, 1372-5 (1918).—The possibility that peroxides play a role in the assimilation process (Willstätter and Stoll, *C. A.* 12, 1889) had already been pointed out by S. (*Sitzungsber. Ges. Beförd. ges. Naturwiss. Marburg* 1907, 158); at the time he suggested that the first stage in assimilation might be represented by the scheme  $\text{C}^{--}(\text{O}^+) + 2\text{H}^+ +$

influenced equil.,  $\text{C}(\text{OH})_4 \rightleftharpoons \text{H}_2\text{C}(\text{OOH})_2$ , might be assumed. The symbol  $\text{C}^{--}(\text{O}^+)$ , was based on the Helmholtz theory of light absorption according to which a specific light effect can occur only in the presence of polar elec. charges on the mols. On the basis of the electronic valence theory since established, chiefly by Stark, this view assumes a somewhat different form. A simple union between 2 atoms is brought about by the elec. fields of force between the positive spheres of the 2 atoms and 2 negative valence electrons, each genetically related to one of the atoms but also united to the

other; this may be represented by the scheme  $\text{A}_1 \begin{array}{c} \diagup \text{O} \diagdown \\ \diagdown \text{O} \diagup \end{array} \text{A}_2$ , where o represents the

electron, — its union with its own atom and ... its union with the other atom. In a double union, 4 valence electrons are brought close together and mutually repel each other to some extent, bulging out the fields of force and thus weakening the union and making possible combination with neighboring fields by intermol. rearrangement

or addition of foreign complexes. The simpler and more compact the field of force of an electron, the higher is its frequency and therefore the shorter the wave lengths at which its absorption spectrum lies. When the radiant energy absorbed by resonance so affects the field of an electron that it can combine with neighboring fields of its own or of a foreign mol., photochem. processes are possible. Whether the system  $\text{CO}_2\text{-H}_2\text{O}$  in its (ultraviolet) region of electronic resonance is capable of undergoing a photochem. conversion into a peroxide-like compd. and the chlorophyll complex merely shifts the spectral sensitiveness of the reaction must be decided by special expts. It seems more probable that the  $\text{H}_2\text{CO}_3$  complex by addition to the chlorophyll mol. has its fields of electronic valence so influenced that it can undergo the specific light reaction in question.

CHAS. A. ROUVILLER.

**Strychnos alkaloids. XXIV. Cause of the violet color reaction of cacotheline and related nitro compounds of the brucine series.** HERMANN LEUCHS. Univ. Berlin. *Ber.* 51, 1375-89(1918).— $\text{HNO}_3$  reacting on brucine produces the well known red brucine reaction, which depends on the change of the two  $\text{MeO}$  groups into a quinone (C. A. 5, 3430); further action of the  $\text{HNO}_3$  results in the introduction of a  $\text{NO}_2$  group and addition, in a way not detd., of  $\text{H}_2\text{O}$ , the final product being cacotheline (a),  $\text{C}_{21}\text{H}_{21}\text{O}_7\text{N}_3\cdot\text{HNO}_3$  (C. A. 6, 365), which, therefore, is apparently a nitrate of a hydrated and nitrated quinone unless the  $\text{H}_2\text{O}$ , on its addition, has destroyed the quinone grouping or the series of reactions is more complicated than would seem to be indicated by the formulas of the successive intermediate compds. The behavior of the red-yellow (a) towards  $\text{SO}_2$  in mineral acid solns., however, was up to the present not in harmony with a quinone structure, for instead of giving a colorless or lighter quinol it yields deep violet or dark green compds. with acids, apparently isomeric with the original yellow or red-yellow salts (C. A. 4, 2462). The compd.  $\text{C}_{21}\text{H}_{21}\text{O}_7\text{N}_3\cdot\text{MeNO}_3$  (b), obtained by the action of  $\text{HNO}_3$  on methylbrucine, likewise gives the violet color reaction with  $\text{SO}_2$ , and forms the subject of the present investigation. This time it was not prepd. from methylbrucine but by boiling 18 g. of the  $\text{Me}_2\text{SO}_4$  compd. of brucine for 1 hr. in 540 cc. of 10%  $\text{HNO}_3$ , letting stand in ice a long time, filtering and covering first with ice-cold 10%  $\text{HNO}_3$  and then with  $\text{Me}_2\text{CO}$ ; yield of air-dried product, 8 g. From cold soln. it seps. in orange tablets with 2  $\text{H}_2\text{O}$ , which are at first quite sol. in boiling  $\text{H}_2\text{O}$  (about 1:5) until difficultly sol. red anhydrous tables sep. In order to test for the presence of a quinone group, 0.54 g. in 25 cc. hot  $\text{H}_2\text{O}$  was treated with 0.42 g.  $\text{NH}_2\text{OH}\cdot\text{HCl}$  in 5 cc.  $\text{H}_2\text{O}$  and heated 0.5 hr. at  $100^\circ$ ; when acidified with 3 cc. of 5  $N$   $\text{HCl}$  and cooled in ice this gave *cacotheline chloromethylate mono-oxime*,  $\text{C}_{22}\text{H}_{23}\text{O}_7\text{N}_4\text{Cl}\cdot 2\text{H}_2\text{O}$ , yellow needles, gives a red color with  $\text{SnCl}_2$  in concd.  $\text{HCl}$  and with  $\text{Zn}$  and  $\text{HCl}$  a greenish color which then fades out; it gradually carbonizes without melting on heating and dissolves easily in alkalis and  $\text{NH}_4\text{OH}$  with yellow color. As only one  $\text{NOH}$  group enters in spite of the large excess of  $\text{NH}_2\text{OH}$  used, the product is possibly a nitrosophenol. A further test for the presence of the quinone grouping in (b) was sought by treating 3 g. of the (b). 2  $\text{H}_2\text{O}$  in 21 cc. of 12  $N$   $\text{HCl}$  with 2 g.  $\text{Sn}$  powder; the soln. became brown, then violet and finally colorless; after 1-2 hrs. it was dild. to 80 cc., whereupon 2.4 g. of a faintly greenish cryst. ppt. sepd. and concn. *in vacuo* yielded further crops of the same compound,  $\text{C}_{22}\text{H}_{23}\text{O}_8\text{N}_3\text{Cl}\cdot\text{HCl}\cdot\text{SnCl}_4\cdot 6\text{H}_2\text{O}$  (total yield, 4.4 g.), broad, rectangular prisms, becomes faintly greenish in the air; 2 g. in 100 cc.  $\text{H}_2\text{O}$  freed from  $\text{Sn}$  with  $\text{H}_2\text{S}$ , evapd. *in vacuo*, finally over  $\text{KOH}$ , and rubbed with 2 cc. of 5  $N$   $\text{HCl}$ , gives 0.9 g. of the *hydrochloride*,  $\text{C}_{22}\text{H}_{23}\text{O}_8\text{N}_3\text{Cl}\cdot\text{HCl}$ , 4- or 6-sided tables with 1 mol. solvent from  $\text{H}_2\text{O}$ , anhydrous needles from alc., sol. in  $\text{KOH}$  with pink color quickly changing to blue, especially on warming, and then yellow, with loss of  $\text{NH}_3$ , sol. in  $\text{NH}_4\text{OH}$  with yellow color changing to brown and then to yellow again, becomes brown and carbonizes from  $260^\circ$  up, gives no color with  $\text{Na}_2\text{SO}_3$  or  $\text{SO}_2$ . The 4 H atoms

used up in the reduction of (b) apparently served, besides the formation of the  $\text{NH}_2$  group, to reduce the quinone to the quinol grouping. On the other hand  $\text{SO}_2$  not only leaves the  $\text{NO}_2$  group unchanged but the 2 atoms of H which would serve for the reduction of the quinone are not taken up; when 3 g. (b) is warmed with 1 mol.  $\text{Na}_2\text{SO}_3$  in 45 cc.  $\text{H}_2\text{O}$  on the  $\text{H}_2\text{O}$  bath for a short time, the soln. turns violet and soon deposits crystals; after 1 hr. in ice there is obtained 1.3 g. dark violet, almost black prisms (c) with metallic luster, of the compn.  $\text{C}_{21}\text{H}_{21}\text{O}_7\text{N}_3 \cdot \text{MeSO}_3\text{H}$  with 5.36% (more than 2 mols.)  $\text{H}_2\text{O}$  (with 2 mols.  $\text{NaHSO}_3$  the yield from 3 g. (b) is 2.9 g.). In the cold the reaction is much slower (1.9, 2.5 and 2.7 g. after 1, 2 and 4 days, resp.); sometimes the reaction follows a different course; the product seps. in colorless, silky leaflets with 6  $\text{H}_2\text{O}$  which also change into the violet (c), but about 1 week, with frequent shaking, is required for this change to be complete; with strong acids the salt evolves  $\text{SO}_2$  and on long standing in the dry state or warming with  $\text{H}_2\text{O}$  it goes over into (c). In (c) the  $\text{SO}_3\text{H}$  is attached with extraordinary firmness for the (c) dissolves in cold concd.  $\text{H}_2\text{SO}_4$  and is reprecipitated unchanged by  $\text{H}_2\text{O}$ . When 1 g. (c) is boiled 2 min. with 20 cc. of 2.5 N  $\text{HNO}_3$  and cooled in ice or 3 g. is kept 10 min. with 30 cc. of 5 N  $\text{HNO}_3$  at  $20^\circ$  and then diluted with 90 cc.  $\text{H}_2\text{O}$  there is obtained 70% of a compound,  $\text{C}_{22}\text{H}_{22}\text{O}_7\text{N}_3\text{SO}_3\text{H}$ , (d), red-yellow domatic prisms or 3-sided and trapezoid leaflets with 2  $\text{H}_2\text{O}$ , brick-red when anhydrous, which seems to take up H very readily, e. g., in contact with a Ni spatula when moist, but especially in acid solns., giving green-brown crystals, perhaps of a quinhydrone nature, and finally violet crystals; this also seems to occur, by autoreduction on recrystn., the red-yellow color of the crude product changing to brown-yellow or greenish brown; with Ni in HCl,  $\text{SO}_2$  on the  $\text{H}_2\text{O}$  bath or  $\text{NH}_4\text{OH}$  in acid soln. it regenerates (c) while in alk. soln. with  $\text{NH}_4\text{OH}$  and subsequent acidification it gives  $\text{SO}_2$  and cacotheline methochloride oxime. With Sn in concd. HCl it yields, after removal of the Sn with  $\text{H}_2\text{S}$  and evapn. *in vacuo*, an amorphous residue which, on rubbing with a little  $\text{H}_2\text{O}$ , at first forms small tables, presumably of the aminoquinol hydrochloride  $\text{C}_{22}\text{H}_{22}\text{O}_8\text{N}_3\text{SO}_3\text{H} \cdot \text{HCl}$ , which, however, redissolve on further diln. and are replaced by a sandy ppt. of a non-basic anhydride,  $\text{C}_{22}\text{H}_{22}\text{O}_7\text{N}_3\text{S}$ , needles sol. in about 4000 parts  $\text{H}_2\text{O}$  at  $100^\circ$ , does not change up to  $290^\circ$ , sol. in  $\text{NH}_4\text{OH}$  with a pink color changing to yellow, in NaOH with pink color changing to blue, at once reduces  $\text{AgNO}_3$ , sol. in dil. HCl but depositing the HCl salt at a certain concn., gives no color with  $\text{SO}_2$ , unchanged by  $\text{NH}_4\text{OH} \cdot \text{HCl}$  but loses  $\text{SO}_2$  when heated with  $\text{NH}_4\text{OH}$  in alk. soln. The green-brown and the violet compds. can be reduced in the same way. In  $\text{NH}_4\text{OH}$  soln. protected from the air (c) is quite stable but in the presence of air the violet soln. soon becomes red-yellow and is found to contain about 10% (d), but about 60% is changed into a compound,  $\text{C}_{21}\text{H}_{22}\text{O}_{11}\text{N}_3\text{S}$  (e), red-yellow domatic prisms and polyhedrons with 2  $\text{H}_2\text{O}$ , turns brown  $230^\circ$ , carbonizes  $280-90^\circ$ , easily sol. in  $\text{NH}_4\text{OH}$  and alkalis with pure yellow color, neutralizing 2 mols., splits off  $\text{SO}_2$  with warm N alkalis, gives only a very faint violet color with  $\text{SO}_2$  or  $\text{SnCl}_2$  (probably due to impurities); with Zn and HCl, it becomes brown, then faintly violet and finally colorless with evolution of  $\text{H}_2\text{S}$ . The structure of (b) and similar salts is, as far as detd., to be represented by  $\text{C}_{17}\text{H}_{19}\text{O} \{ -\text{CO} \cdot \text{N} < -\text{NO}_2; \text{NMeX} - \text{CO} \cdot \text{CO} - \text{CH} \cdot \text{CH} \cdot (\text{OH}) \}$  (X =  $\text{NO}_2$ ,  $\text{SO}_3\text{H}$ , etc.). That (c) is a quinol is shown by its oxidation to (d) and its regeneration with  $\text{SO}_2$ . Since there is a quinone group in (b), H must add to this grouping in the formation of (c) but this H is not furnished by the  $\text{SO}_2$ , since it enters the mol. unchanged and the H content of (b) and (c) are alike. The H must therefore be supplied intramol. under the influence of the  $\text{SO}_3\text{H}$ , and it is probably the sec. alc. grouping which supplies this H:  $-\text{CO} \cdot \text{CO} - + -\text{CH}(\text{OH}) - \rightarrow -\text{C}(\text{OH}) : - \text{C}(\text{OH}) - + > \text{CO}$ . The resulting  $> \text{CO}$  group might then combine, like bisulfite compds., with the  $\text{SO}_3\text{H}$  residue already attached to the N;  $\rightarrow \text{NMeSO}_3\text{H} + > \text{CO} \rightarrow$

→ $\text{NMeSO}_2\text{O.C(OH)}<$ . Quadrivalent basic O and salt-like union of the acid residue with it is also a possibility; this might explain the strikingly intense color. But the masking of the  $\text{H}_2\text{SO}_4$  is not sufficient to produce the violet color: the quinol grouping must also be present, for the quinone (*d*), although containing masked  $\text{H}_2\text{SO}_4$ , is only red-yellow. The  $\text{NO}_2$  group also plays a part; the amino, quinol and its anhydride are colorless and do not react with  $\text{SO}_2$ .

CHAS. A. ROUVIER.

**Reducibility of formic acid.** K. A. HOFMANN AND HELGE SCHIBSTED. Techn. Hochschule, Berlin. *Ber.* 51, 1389-98(1918).—Attempts to reduce  $\text{HCO}_2\text{H}$  to  $\text{HCHO}$  and  $\text{MeOH}$  with  $\text{H}$  under the most varied conditions never resulted in a greater yield than 4%. The  $\text{HCHO}$ -morphine  $\text{H}_2\text{SO}_4$  reaction was used only for identification and approx. detn. of the  $\text{HCHO}$ , quant. estimations of the  $\text{HCO}_2\text{H}$ ,  $\text{HCHO}$  and  $\text{MeOH}$  being made by exact titration. (1) In one portion of the product the free  $\text{HCO}_2\text{H}$  was titrated with 0.1 *N* alkali and litmus. (2) To another portion was added approx. twice the calcd. amt. of 0.1 *N*  $\text{I}$ , then 10%  $\text{KOH}$  to strong alkalinity, and the soln. acidified after 10 min. with dil.  $\text{HCl}$  and the excess of  $\text{I}$  titrated with  $\text{Na}_2\text{S}_2\text{O}_3$ . If the soln. originally does not contain more than 5%  $\text{HCO}_2\text{H}$  the reaction proceeds according to the equation  $\text{HCHO} + \text{I}_2 + 3\text{KOH} = \text{HCO}_2\text{K} + 2\text{KI} + 2\text{H}_2\text{O}$ ; higher concns. of formate have an increasing reducing action on the  $\text{I}$ . (3) The  $\text{HCO}_2\text{H}$ ,  $\text{HCHO}$ ,  $\text{Me}_2\text{CO}$  and  $\text{MeOH}$  are oxidized to carbonate when a third portion of the product is heated 0.5 hr. on the  $\text{H}_2\text{O}$  bath with 5 times the calcd. amt. of 0.5 *N*  $\text{KMnO}_4$  and 10 cc. of 10%  $\text{KOH}$ ; the soln. is then acidified with dil.  $\text{H}_2\text{SO}_4$ , the  $\text{MnO}_2$  and  $\text{KMnO}_4$  are reduced with 0.5 *N*  $(\text{CO}_2\text{H})_2$  and the excess of the  $(\text{CO}_2\text{H})_2$  is titrated with 0.5 *N*  $\text{KMnO}_4$ . **Reduction in  $\text{H}_2\text{O}$  with nascent  $\text{H}$  under atm. pressure:** 65 g. granulated  $\text{Zn}$  were treated 12 hrs. with the catalyst and a little  $\text{H}_2\text{O}$ , then allowed to stand 2 days with 49 g.  $\text{HCO}_2\text{H}$  and 100 cc.  $\text{H}_2\text{O}$  and completely distd. at  $100-20^\circ$ ; below are the amts. in g. of the  $\text{HCHO}$ ,  $\text{MeOH}$  and total reduced  $\text{HCO}_2\text{H}$ , resp., obtained with different catalysts;  $\text{Hg}$  (corresponding to 2 g.  $\text{HgSO}_4$ ), 0.0033, 0, 0.0099;  $\text{Cd}$  (2 g.  $\text{CdSO}_4 + \frac{1}{2} \text{H}_2\text{O}$ ), 0.009, 0.234, 1.009;  $\text{Cu}$  (2 g.  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ ), 0.0213, 0.2865, 1.301;  $\text{V}_2\text{O}_5$  (0.5 g.  $\text{NaVO}_3$ ), 0.0284, 0.3251, 1.487;  $\text{V}_2\text{O}_5$  with 10 g.  $\text{HCO}_2\text{Na}$ , 0.043, 0.3535, 1.655. Addition of dil.  $\text{H}_2\text{SO}_4$  facilitated the evolution of the  $\text{H}$  without materially increasing the yields, although in the case of  $\text{Cd}$  0.03 g.  $\text{HCHO}$  was obtained and with  $\text{Hg}$  0.39 g.  $\text{MeOH}$ . In neutral soln. with 0.1 g.  $\text{PdCl}_2$ , 40 g.  $\text{HCO}_2\text{Na}$  and 100 cc.  $\text{H}_2\text{O}$  the yields were 0.002, 0.23, 0.991 g. With  $\text{Zn}$  dust with and without  $\text{Pd}$  2.9 and 2.2% yields of  $\text{MeOH}$ , without  $\text{HCHO}$ , were obtained from  $\text{HCO}_2\text{Na}$ . From 60 cc. of 15%  $\text{HCO}_2\text{H}$  dist. on the  $\text{H}_2\text{O}$  bath were obtained: with 2 cc. of 1%  $\text{H}_2\text{PtCl}_6$  0.0095 g.  $\text{HCHO}$ , 0.0151 g.  $\text{MeOH}$  ( $\text{Zn}$  used 4.84 g.); the same + 5 g.  $\text{HCO}_2\text{Na}$ , 0.0104 and 0.0178 g. ( $\text{Zn}$  used 4 g.).  $\text{Pd}$  and  $\text{Ir}$  are about equal to  $\text{Pt}$ .  $\text{Rh}$  is somewhat more effective. **Reduction under pressure:** 5.6 g.  $\text{Zn}$ , 60 cc. of 15%  $\text{HCO}_2\text{H}$  and the catalyst in sealed tubes of about 150 cc. capacity filled with  $\text{CO}_2$  were heated 72 hrs. at  $70^\circ$ ; the pressure developed, calcd. on the basis of the max. possible amt. of  $\text{H}$  evolved, was about 20 atm. Below are the amts. of  $\text{HCHO}$  and  $\text{MeOH}$  formed and of  $\text{Zn}$  used, resp., with different catalysts:  $\text{Pt}$  (2 cc. of 1%  $\text{H}_2\text{PtCl}_6$ ), 0.003, 0.010, 4.56;  $\text{Pt} + 5$  g.  $\text{HCO}_2\text{Na}$ , 0.0057, 0.0106, 2.53;  $\text{Pd}$  (2 cc. of 1%  $\text{PdCl}_2$ ), 0.0045, 0.0052, 4.21; no catalyst, 0.0006, 0.004, 0.55.  $\text{Rh}$  and  $\text{FeSO}_4$  gave perceptibly more  $\text{HCHO}$ ;  $\text{Ir}$ ,  $\text{Ru}$  and  $\text{NaVO}_3$  were not more effective. The above results, however, represent only the difference between the amts. of  $\text{HCHO}$  and  $\text{MeOH}$  formed by reduction of the  $\text{HCO}_2\text{H}$  and those destroyed by further reduction; thus, if 9 cc. of 35%  $\text{HCHO}$  is heated as above with 2 cc. of 1%  $\text{PdCl}_2$ , 44% of the  $\text{HCHO}$  disappears with partial formation of  $\text{MeOH}$ . **Reduction with simultaneous catalytic decomposition of the  $\text{HCO}_2\text{H}$ :** Marquard clay tubes impregnated with solns. of salts of the  $\text{Pt}$  metals and then ignited powerfully catalyze the reaction  $\text{HCO}_2\text{H} = \text{CO}_2 + \text{H}_2$ , but even under these conditions the nascent  $\text{H}$  has but small power to reduce  $\text{HCO}_2\text{H}$ ;

40 g.  $\text{HCO}_2\text{Na}$  distd. over palladinized tubes gave only traces of  $\text{HCHO}$  and 0.05 g.  $\text{MeOH}$ . Free  $\text{HCO}_2\text{H}$  in dil. soln. is not decompd. by the salts of the Pt metals even after 44 hrs. at  $70-80^\circ$  in closed tubes. Addition of 5 g.  $\text{HCO}_2\text{Na}$  to 60 cc. of 15%  $\text{HCO}_2\text{H}$  increases the catalytic decompn. on distg. over Rh or Pd tubes 30-40% without yielding more than traces of  $\text{HCHO}$ . Concd. (85%)  $\text{HCO}_2\text{H}$  with 20%  $\text{HCO}_2\text{Na}$  is catalyzed extensively by Ir, Pt or Pd tubes on distn. but again with formation of only traces of  $\text{HCHO}$ . The vapors of  $\text{HCO}_2\text{H}$  passed over the catalyst are decompd. into  $\text{CO}_2 + \text{H}_2$  by Pd sponge at  $110^\circ$ , Pt sponge at  $120^\circ$ , Cu powder at  $190^\circ$ , reduced Ni and Cd at  $280^\circ$ , and into  $\text{CO} + \text{H}_2\text{O}$  by  $\text{TiO}_2$  and  $\text{WO}_3$  above  $170^\circ$ , while  $\text{SiO}_2$ ,  $\text{ZrO}_2$ ,  $\text{Al}_2\text{O}_3$  and  $\text{UO}_2$  also slightly catalyze the reaction  $2\text{HCO}_2\text{H} = \text{HCHO} + \text{CO}_2 + \text{H}_2\text{O}$ . These results are not markedly changed when the  $\text{HCO}_2\text{H}$  is passed with steam over the catalyst; in the most favorable cases barely detectable amts. of  $\text{HCHO}$  are formed at temps. not much beyond  $150^\circ$ . Asbestos favors the decompn. into  $\text{CO} + \text{H}_2\text{O}$  at low temps., the ratio  $\text{CO}:\text{H}_2$  remaining quite const. at 0.04 from  $196-296^\circ$  with pure asbestos and at 0.24 with Ni asbestos. Sugar charcoal at  $275-90^\circ$  gave 0.005 g.  $\text{HCHO}$  and 0.004 g.  $\text{MeOH}$  with 4.8 g.  $\text{HCO}_2\text{H}$  without any noticeable difference when the acid vapors were passed over the catalyst mixed with  $\text{CO}_2$  or with  $\text{H}_2$ ; with blood charcoal at  $260-70^\circ$  were obtained 0.005 g.  $\text{HCHO}$  and 0.041 g.  $\text{MeOH}$  from 4 g.  $\text{HCO}_2\text{H}$ .

CHAS. A. ROUILLER.

**Preparation of formaldehyde and methyl alcohol from formates.** K. A. HOFMANN and HELGE SCHIBSTED. Techn. Hochschule, Berlin. *Ber.* 51, 1398-418(1918); cf. preceding abstr.— $\text{HCHO}$  and  $\text{MeOH}$  can be obtained from formates with such good yields that this may become a com. method of prepn. of these substances from  $\text{CO}_2$  or  $\text{CO}$ . In no case does the reduction of  $\text{HCO}_2\text{H}$  by added  $\text{H}$  or its reaction with  $\text{CO}$  or that of  $\text{CO}$  with  $\text{H}$  have any influence on the yields; it is never truly a case of reaction in the gas phase but an intramol. rearrangement of the formate mols., which, to be sure, is greatly influenced by the manner of heating, the  $\text{H}_2\text{O}$  content and other admixtures. Also when  $\text{HCO}_2\text{H}$  vapors are passed over catalysts it is only the part combined as formate in an intermediate stage which plays a decisive role in the yields. These formates,  $(\text{HCO}_2)_2\text{M}'$ , probably yield primarily only  $\text{M}'\text{CO}_2 + \text{HCHO}$  and the latter then, depending on the nature of the contact substance, undergoes various changes, the most important of which is the rearrangement into  $\text{MeOH}$  and  $\text{HCO}_2\text{H}$ . That this takes place directly from  $\text{HCO}_2\text{H}$  is doubtful for not only the formates of strong bases (Ca, Ba, Sr, Li) give  $\text{MeOH}$  but so do also those of weak bases (Zn, Th) and, indeed, the better yields; the  $\text{HCHO}$  is probably formed chiefly from  $\text{HCO}_2\text{Me}$ . The following were found to be the temps. at which the evolution of gas from the various formates was marked and continuous: Cu  $170^\circ$ , Pb  $195-200^\circ$ , Ni  $210^\circ$ , Zn  $240-5^\circ$ , Fe'  $245-50^\circ$ , Mn  $295-300^\circ$ ,  $\text{UO}_2$   $317^\circ$ , Ba  $325^\circ$ , Ca  $335^\circ$ , Mg  $340-5^\circ$ , Sr  $355^\circ$ , Li  $355^\circ$ , Na  $355^\circ$ , K  $375^\circ$ . *Decompn. of  $(\text{HCO}_2)_2\text{Zn}$ :* The formates were heated in currents of various gases in metal baths or electrically heated tubes. With the exception of steam, the nature of the gas ( $\text{CO}_2$ ,  $\text{CO}$ ,  $\text{H}_2$ ,  $\text{N}_2$ , air) has no influence on the yield of  $\text{HCHO}$ ,  $\text{MeOH}$  and total reducing products.  $\text{H}_2\text{O}$  vapor in the small concn. in which it occurs in gases washed at room temp. has a slight unfavorable influence when the salt is finely powdered and heated very rapidly; if the salt is coarsely cryst. it distinctly increases the  $\text{HCHO}$  yield when the decompn. temp. is reached rapidly. Large amts. of  $\text{H}_2\text{O}$  vapor (such as are obtained by passing the gases through  $\text{H}_2\text{O}$  at  $80^\circ$ ) are very harmful, 90% of the reaction proceeding with evolution of  $\text{H}_2$ , according to the equation  $\text{HCO}_2\text{H} = \text{CO}_2 + \text{H}_2$  or  $(\text{HCO}_2)_2\text{Zn} + \text{H}_2\text{O} = \text{ZnO} + 2\text{CO}_2 + 2\text{H}_2$ . The state of subdivision of the salt has a great influence, the coarse crystals giving considerably less  $\text{HCHO}$  and total reducing products than the finely divided form distributed on asbestos. This is due to the sensitiveness of the  $\text{HCHO}$  first formed to contact in-

fluences; when the salt is finely divided, the HCHO escapes more quickly into the gas space. Similarly, the rapidity with which the current of gas is passed through the heated mixt. has a great influence; in a rapid current of air the HCHO escapes practically all unchanged while in a slow current it is changed largely into MeOH. If the salt is finely divided, the rapidity with which it is heated from without to the decompn. temp. has no influence on the HCHO and total yields, but if it is present in coarse crystals the HCHO diminishes with rapid heating. Under the most favorable conditions the yield of HCHO is about 25% and that of total reducing substances 40%.  $\text{HCO}_2\text{Me}$ , b.  $32.5^\circ$ , d. 0.9742, was obtained in 3.21 g. yield from 100 g. of the Zn salt at  $260-80^\circ$ . Small amts of empyreumatic substances are also formed. Addition of 20% Zn vanadate, molybdate and tungstate diminish greatly the HCHO and somewhat the total yields; infusorial earth, quartz sand and sugar charcoal are indifferent;  $\text{Al}_2\text{O}_3$  and  $(\text{HCO}_2)_2\text{Al}$  diminish the yields of HCHO and MeOH almost to zero; finely divided Ni and  $(\text{HCO}_2)_2\text{Ni}$  decomp. the products almost completely into CO and H, with 4%  $\text{CH}_4$ . Cu and  $(\text{HCO}_2)_2\text{Cu}$  reduce the HCHO to 1% and less;  $\text{HCO}_2\text{Li}$  and other easily fusible substances likewise reduce the HCHO because, owing to the sintering of the mass, it cannot escape quickly. The decompn. of  $(\text{HCO}_2)_2\text{Zn}$  at  $240^\circ$  is about 60% into  $\text{HCHO} + \text{ZnCO}_3$  and, when  $\text{H}_2\text{O}$  is excluded, 40% into  $\text{CO} + \text{H}_2 + \text{ZnO} + \text{CO}_2$ ; if a little  $\text{H}_2\text{O}$  vapor is present, the amt. of CO diminishes and that of H increases.

*Decompn. of other formates:* The Li salt, owing to the high temp. at which it decomp. ( $350^\circ$ ), and on account of the strongly basic nature of its oxide, gives only little HCHO and instead yields  $\text{Me}_2\text{CO}$ , MeOH, furfural, pyruvic acid, empyreuma and charcoal. The more slowly it is heated the more the gaseous products increase at the expense of the  $\text{Me}_2\text{CO}$  and MeOH; a little  $\text{H}_2\text{O}$  vapor increases the total reducing substances while much steam is injurious; H seems to be better than  $\text{CO}_2$ . When  $\text{H}_2\text{O}$  is present, the ratio  $\text{CO}:\text{H}_2$  in the evolved gases is 9-10, the reaction  $2\text{HCO}_2\text{Li} + \text{CO}_2 = \text{Li}_2\text{CO}_3 + 2\text{CO} + \text{H}_2\text{O}$  proceeding 4-5 times more rapidly than the reaction  $2\text{HCO}_2\text{Li} = \text{Li}_2\text{CO}_3 + \text{CO} + \text{H}_2$ . The Pb salt, decomp. at around  $200^\circ$ , gives HCHO and very much MeOH with relatively little H and CO; H has a beneficial effect in that it reduces the PbO formed which otherwise oxidizes some of the HCHO and MeOH;  $\text{H}_2\text{O}$  vapor in moderate concn. also has a favorable influence; CO is indifferent; rapid heating gives better results than slow heating; in the gaseous products the ratio  $\text{CO}:\text{H}_2$  is very small (0.15). The Tl salt (10 g.) in moist  $\text{CO}_2$  gives 2 mg. HCHO, 90 mg. MeOH, etc.,  $\text{CO}:\text{H}_2$  0.05-0.11; for the Cd salt the values are 4, 40. 0.05; the Co salt yields only traces of MeOH, etc.,  $\text{CO}:\text{H}_2$  0.36; the Cr salt gives 2 mg. HCHO, 14 mg. MeOH, etc.,  $\text{CO}:\text{H}_2$  0.85; the Al salt gives no HCHO or MeOH; the Sn salt gives a good yield of HCHO, almost no MeOH,  $\text{CO}:\text{H}_2$  0.35; the salts of the Y earths give very perceptible amts. of HCHO, some  $\text{Me}_2\text{CO}$ , much MeOH, some charcoal (total reducing substances 27%); the Mg salt forms little HCHO, some  $\text{Me}_2\text{CO}$ , relatively much MeOH, some empyreuma and charcoal (total volatile reducing products 25%); the Ca salt behaves like the Mg salt (total volatile products 17%); the Mn salt gives little HCHO, some  $\text{Me}_2\text{CO}$ , relatively much empyreuma and charcoal (total volatile products 30%).

*Conversion of  $\text{HCO}_2\text{H}$  into HCHO and MeOH in contact with a substance which changes chemically:* The conversion can be satisfactorily effected by so choosing the contact substance and the temp. that formates are formed which then decomp. into HCHO and MeOH. As contact substances the best are the oxides (obtained by decompn. of the formates at low temps.) of Zn and of the rare earths of the Y and didymium groups, especially  $\text{ThO}_2$ ; less efficient are CaO, MgO, MnO and FeO. The  $\text{HCO}_2\text{H}$  is either dropped upon the oxide loosely spread out in a distg. flask or it is heated to  $80^\circ$  and its vapors are carried by means of dry H,  $\text{CO}_2$  or N over the oxide, mixed with asbestos, in a short, glass tube. The process differs from that based on the decompn. of preformed formates in that the HCHO

formed passes over a comparatively large surface of heated oxide and therefore undergoes a more extensive conversion into  $\text{HCO}_2\text{Me}$ ,  $\text{MeOH}$ , aldol-like compds., then  $\text{Me}_2\text{CO}$ , empyreuma, furfural, etc. The addition of Cu powder, sugar charcoal, tungstates, etc., has the same deleterious effects as in the decompn. of formates. Zn dust for a time increases the yield by reducing the formates to some extent but as it is thereby oxidized to ZnO its beneficial effect soon ceases. As the  $\text{HCO}_2\text{H}$  is decompd. to a considerable extent at the reaction temp. before it reaches the contact substance the yield of reducing products is markedly less than in the decompn. of pre-formed formates; the  $\text{H}_2\text{O}$  from the decompd. acid also exerts a harmful influence. In order to obtain, with the best contact substances ( $\text{ZnO}$  and  $\text{ThO}_2$ ), practically the same yields of  $\text{HCHO}$ ,  $\text{MeOH}$ , etc., as from pre-formed formates the oxide is satd. at about  $200^\circ$  with  $\text{HCO}_2\text{H}$  vapors (as dry as possible) carried over with  $\text{CO}_2$ , then the temp. is raised to  $250\text{--}70^\circ$  until the formates are to a great extent decompd., the oxide is cooled to  $200^\circ$ , again satd., etc. In the case of  $\text{Li}_2\text{CO}_3$ -asbestos it would seem that a basic glyoxylate, rather than  $\text{HCHO}$ , is the primary product.

CHAS. A. ROUILLER.

Action of potassium ferricyanide on alizarin in alkaline solution and the constitution of the hydroxyanthraquinones in their salts. ROLAND SCHOLL AND A. ZINKE. Univ. Graz and Techn. Hochschule, Dresden. *Ber.* 51, 1419-35(1918).—When an alk. soln. of alizarin (*a*) is treated with  $\text{K}_3\text{Fe}(\text{CN})_6$ , the acid (I) is formed, the structure of which permits of drawing certain conclusions as to the constitution of (*a*) in alk. soln. Perkin, v. Georgievics and Dimroth believe that hydroxyanthraquinones in the form of their salts have the quinoid structure but up to the present there is no expl. basis for such a formulation. One fact, however, has long been known which with our present views the ordinary benzenoid conception of the salts of hydroxyanthraquinones does not satisfy, *vis.*, the mordant-dye nature of these compds. first observed in the case of hystazarin (*b*) by Noelting. According to Werner's theory of mordant dyes that in the majority of cases such dyes form metallic inner complex salts this property in (*b*) seems reconcilable only with the quinoid structure (II). But while (*b*) lakes with metallic mordants like 1-hydroxyanthraquinone, (*a*) 2-Me ether and other compds. with a HO in the *o*-position to the C:O group, it does not, like the latter, form an inner complex with anhydrous  $\text{SnCl}_4$  (Pfeiffer) and in the free form would therefore seem to be a true pyrocatechol deriv. (III). Adopting these views, the formation of (I) from (*a*) would indicate that (*a*) in alk. soln. has the *p*-quinoid structure (IV), for if it had the *o*-quinoid form, as believed by v. Georgievics, it should yield (V) instead of (I). This quinoid structure of hydroxyanthraquinone salts applies only to those formed like the lakes of (*b*), *i. e.*, by the action of metallic hydroxides (and  $\text{NH}_4\text{OH}$ ), and not to Pfeiffer's  $\text{C}_6\text{H}_5\text{N}$  salts, inner complex  $\text{SnCl}_4$  compds. and Sn lakes formed from the latter by the action of  $\text{H}_2\text{O}$ , which from their method of formation and properties very probably have the benzenoid structure (VI) assigned to them by P. It would therefore follow that hydroxyanthraquinones can form tautomeric benzenoid and quinoid salts, but although this affords a good explanation of many phenomena in this field the assumption of quinoid formation to account for the mordant properties of (*b*) and in general for the behavior of hydroxyanthraquinones towards metallic hydroxides is superfluous. Just as in Pfeiffer's derivs. of  $\alpha$ -hydroxyanthraquinone derivs. an inner complex is formed between the H (or metal) of the HO (or MO) and the C:O group in the *o*-position to it, so in lakes of (*b*) it may be assumed that there is an inner complex formation between the MO and the *p*-C:O groups (VII); in 2-hydroxyanthraquinone, indeed, which possesses mordant properties, though not to so marked an extent as the 1-HO isomer, the formation of such an inner complex ring is the only possibility. Moreover (*b*) and all other di- and polyhydroxyanthraquinones with HO groups in the *o*- or *p*-position to each other also have the power of forming inner complex salts or

anions between the two HO groups (VIII), for Weinland and Binder's triazalariniferic acid corresponds in structure with their tripyrocatecholferric and -aluminic acids, and quinizarin forms a similar ferric acid. Twenty g. (a) in 1800 g. H<sub>2</sub>O and 72 g.

KOH cooled in running H<sub>2</sub>O was treated with 160 g. K<sub>3</sub>Fe(CN)<sub>6</sub> in 350 g. H<sub>2</sub>O in the course of 5 min., allowed to stand 15 min., neutralized with concd. HCl, filtered, washed with H<sub>2</sub>O, treated while still moist with aq. NaOAc (whereupon the product dissolved almost completely), filtered at once, again pptd. with concd. HCl, washed thoroughly with H<sub>2</sub>O and dried *in vacuo* over H<sub>2</sub>SO<sub>4</sub>, giving 14-15 g. crude *2-hydroxy-1,4-naphthoquinono-3-vinylglyoxylic acid* (I) as a brown-yellow powder, stable indefinitely at room temp. but begins to decomp. 70-80°, sol. in hot H<sub>2</sub>O but partially decomps. in a few min. on boiling, losing CO<sub>2</sub> and depositing a substance, C<sub>12</sub>H<sub>6</sub>O<sub>4</sub>(?), sol. in NaOH. The crude (I) in dil. NaOAc treated with CaCl<sub>2</sub> gives a violet-brown *calcium salt*, C<sub>14</sub>H<sub>6</sub>O<sub>6</sub>.Ca.7H<sub>2</sub>O, slender rodlets from 300 parts boiling H<sub>2</sub>O, losing 4 mols. H<sub>2</sub>O in boiling H<sub>2</sub>O and sepg. from concd. soln. as the difficultly sol. black-violet *trihydrate*, slender spindle-shaped crystals, best obtained by covering the heptahydrate with H<sub>2</sub>O and heating 1 hr. on the H<sub>2</sub>O bath under an air condenser; it is also obtained in dark brown, opaque pseudomorphs after the rodlet form at room temp. *in vacuo* over CaCl<sub>2</sub> or H<sub>2</sub>SO<sub>4</sub>; when recrystd. from very dil. soln. containing a little CaCl<sub>2</sub> it seps. as the heptahydrate. The above hydrates at 110-20° yield a black-violet *monohydrate*. The very pure heptahydrate boiled some time in concd. soln. deposits, together with the trihydrate, a *dihydrate* in slender, brown-yellow, rhombic leaflets with bronze luster, much more slowly sol. in boiling H<sub>2</sub>O than the mono- and trihydrates and yielding the heptahydrate from dil. soln. The acids liberated from all 4 hydrates yield the heptahydrate with CaCl<sub>2</sub> in NaOAc. S. and Z. believe the hepta- and dihydrates contain a hydrated, the tri- and monohydrates a pure ketone group and that the not quite pure heptahydrate contains an impurity which catalytically accelerates the dehydration of the hydrated ketone and makes it impossible to obtain the dihydrate with boiling H<sub>2</sub>O. The dark salts are also possibly inner complexes. The free (I), obtained pure by hydrolysis of the esters, with alc. KOH, soln. of the resulting K salt in H<sub>2</sub>O, pptn. with HCl and extn. with Et<sub>2</sub>O, forms honey-yellow hydrated leaflets weathering in the air but completely losing the H<sub>2</sub>O (probably chemically combined with the ketone group) only after several days *in vacuo* over H<sub>2</sub>SO<sub>4</sub>. It turns brown above 150°, black above 200° and m. about 230° (decompn.), sol. in cold H<sub>2</sub>O with yellow, in hot H<sub>2</sub>O with yellowish red color changing to yellow again on addition of a little HCl;

the red-yellow concd. alc. solns. are turned red by  $H_2O$ , yellow by a little dil.  $HCl$ ; it dissolves in  $H_2SO_4$  with yellow color and gives a dark red color with alc.  $FeCl_3$ . The salts, excepting those with the alkalis, are difficultly sol. in cold  $H_2O$ ; those of the alk. earths,  $Mg$ ,  $Mn$  and  $Cd$  are cryst. (I) dissolves in alkalis,  $NH_4OH$ ,  $Na_2CO_3$  and  $NaOAc$  with yellowish red color.  $Na_2S_2O_4$  gives with a cold alk. soln. a soln. sensitive to air which is green in thin, violet in thick layers, and becomes light yellow on warming and then red, owing to oxidation. The cold  $NaOH$  soln. is turned emerald-green, then yellow-green by  $Zn$  dust; hot dil.  $HNO_3$  in sealed tubes yields phthalic acid. *Sodium salt*, pptd. from a  $NaOAc$  soln. by solid  $NaOAc$ , seps. in brown-red needles. *Dipotassium salt*, obtained by boiling (I) with a 6.5% soln. of  $KOAc$  in  $MeOH$ , adding  $H_2O$  until the salt is almost dissolved, filtering, cooling and allowing to stand 24 hrs., brown crystals with 2 mols. of  $H_2O$ , 1 of which it loses *in vacuo* over  $H_2SO_4$ . The  $Ag$  salt, a brown-red amorphous ppt. obtained by adding  $AgNO_3$  to the  $K$  salt in  $H_2O$ , when heated 1 hr. on the  $H_2O$  bath with a large excess of  $EtI$  in  $CS_2$ , filtered and quickly shaken with 0.5% aq. (crystd.)  $NaOAc$ , yields a red aq. soln. of the *monoethyl ester* which is at once pptd. with dil  $H_2SO_4$  and taken up in  $CHCl_3$ ; to avoid hydrolysis it should not be allowed to remain in the  $H_2O$  soln. more than 5-10 min. It seps. from  $EtI$  in fine, yellow, cryst. fibers or brown-yellow needles, m.  $149^\circ$ , sol. in org. solvents with yellow-red to yellow, in  $H_2SO_4$  with greenish yellow, in  $Na_2CO_3$  and  $NaOAc$  with red color, gives a violet-red color with alc.  $FeCl_3$ , yields on hydrolysis and treatment with  $CaCl_2$  the above  $Ca$  salt with 7  $H_2O$ . The  $CS_2$  soln. yields 2 *diethyl ether esters*, easily sol. yellow rhombohedral tables from alc. or  $CS_2$ , m.  $85.5-7.0^\circ$ , and less sol. yellow, prismatic needles, m.  $188^\circ$ ; neither gives a color with  $FeCl_3$ . C. A. R.

Synthesis of derivatives of [diethylaminoacetyl]salicylic acid. FRIEDRICH L. HAEN AND MILLY LOOS. Univ. Frankfurt a/M. *Ber.* 51, 1436-47(1918).—*Methyl chloroacetylsalicylate* (a),  $ClCH_2CO_2C_6H_4CO_2Me$ , m.  $62^\circ$ ,  $b_{20}$   $195-200^\circ$ , is obtained on 80-5% yield by slowly adding with cooling 25 g.  $ClCH_2COCl$  to 35 g.  $o-HOC_6H_4CO_2Me$  and 26 g.  $PhNMe_3$ , letting stand 5 hrs., decomp. with ice and dil.  $HCl$  and drying on clay and then *in vacuo* over  $CaO$ ; it may also be prepd. by heating 16 g.  $HOCH_2C_6H_4CO_2Me$  with 10 g.  $ClCH_2CO_2H$  and 5 g.  $PCl_5$  2 hrs. on the  $H_2O$  bath, pouring off from the  $H_3PO_3$ , rinsing with a little  $Et_2O$ , treating with 20 cc.  $PhNMe_3$  with cooling, shaking the following day with  $HCl$ , then with soda and drying the  $Et_2O$  soln. with  $Na_2SO_4$ . Of this, 23 g. are allowed to stand some time with 16 g.  $NaI$  in  $Me_2CO$  (whereby it is converted into the I compd.), freed from the  $Me_2CO$  under slightly diminished pressure, taken up in  $Et_2O$ , shaken with  $NaHSO_3$  or  $Na_2S_2O_3$ , dried with  $Na_2SO_4$  and slowly treated with cooling with 14 g.  $NHEt_3$ . The reaction takes place at once; the pptd.  $NHEt_3 \cdot HI$  (14 g.) is filtered off, the  $Et_2O$  evapd., the residue gently warmed *in vacuo* to remove the excess of  $NHEt_3$ , then dissolved in  $AcOEt$ , treated cold with  $HCl$  gas until acid to Congo and filtered after some time. There is thus obtained 8 g. of the *hydrochloride*, white cryst. ppt., m.  $131^\circ$ , of *methyl [diethylaminoacetyl]salicylate*, m.  $58-9^\circ$ ; *picrate*, m.  $147^\circ$ . *Ethyl chloroacetylsalicylate*, m.  $67^\circ$ ,  $b_{20}$   $130^\circ$ . *Ethyl [diethylaminoacetyl]salicylate*,  $b_{11}$   $136-46^\circ$ ; *picrate*, fine needles from dil. alc., m.  $138^\circ$ ; *chloroplatinate*, m.  $161-2^\circ$ . If the  $NHEt_3$  is allowed to react with (a) instead of the I compd. and worked up as above, the product is *diethylaminoacetyl diethylamide* (b),  $b_{20}$   $134-6^\circ$  (*picrate*, hydrated crystals from alc., m.  $133^\circ$ ), and the  $Et_2O$  soln., after shaking with  $HCl$ , leaves as residue almost the calcd. amt. of  $HOCH_2C_6H_4CO_2Me$ .  $ClCH_2COCl$  and  $NHEt_3$  in cold  $Et_2O$  yield *chloroacetyl diethylamide*,  $b_{20}$   $190-5^\circ$ , strongly irritating to the eyes, which, treated in  $Me_2CO$  with  $NaI$ , freed from  $Me_2CO$  and treated in  $Et_2O$  with  $NHEt_3$ , gives an oil forming a *picrate* identical with that of (b). *Chloroacetylsalicylyl chloride* (c), obtained quant. by treating 20 g.  $ClCH_2CO_2C_6H_4CO_2H$  and a little  $POCl_3$  with 20 g.  $PCl_5$ , warming on a gently boiling  $H_2O$  bath until a clear soln. results (about 1 hr.),

freeing from  $\text{POCl}_3$  *in vacuo* on the  $\text{H}_2\text{O}$  bath, dissolving in  $\text{Et}_2\text{O}$ , filtering and freeing from  $\text{Et}_2\text{O}$  on the  $\text{H}_2\text{O}$  bath,  $b_p$  165–70°. From 5 g. (c) in 30 cc. cold  $\text{AcOEt}$  and 4 g.  $\text{PhNH}_2$  is obtained 5 g. *chloroacetylsalicylanilide*, m. 121°, also obtained in 80% yield from 12 g. of the well dried K salt of  $o\text{-HOC}_6\text{H}_4\text{CONHPh}$  and 6.3 g.  $\text{ClCH}_2\text{COCl}$  in 50 cc.  $\text{AcOEt}$ ; with  $\text{NaI}$  in  $\text{Me}_2\text{CO}$  it gives the *iodo compound*, white crystals, turns brown 118°, m. 128°; this, allowed to stand in cooled  $\text{AcOEt}$  with  $\text{NHEt}_3$ , gives [*diethylaminoacetyl*]salicylanilide, m. 129–30°; *hydrochloride*, m. 131–3°. *Chloroacetylsalicylamide* (d), needles, m. 160°, is obtained in 60% yield by treating the chloride and a trace of  $p\text{-O}_2\text{NC}_6\text{H}_4\text{OH}$  in cold  $\text{Et}_2\text{O}$  with dry  $\text{NH}_3$  to appearance of a yellow color, also, in very poor yield, by rubbing the chloride with  $(\text{NH}_4)_2\text{CO}_3$  until its odor disappears. *Chloroacetylsalicyl*[*chloroacetylamine*],  $\text{ClCH}_2\text{CO}_2\text{C}_6\text{H}_4\text{CONHCOCH}_2\text{Cl}$ , silky needles, m. 133–4°, from 8 g.  $\text{HOC}_6\text{H}_4\text{CONH}_2$ , 18 g.  $\text{PhNMe}_2$  and 16.5 g.  $\text{ClCH}_2\text{COCl}$  allowed to stand some time, is stable in the solid state and in non-aq. solns.; in aq. solns., especially on warming, the acyl groups are split off; cleavage of that on the N alone can easily be affected by quickly dissolving 3 g. of the compd. in 3 cc. warm alc. and pouring into 100 cc.  $\text{H}_2\text{O}$  containing 0.7 cc. of 25%  $\text{NH}_4\text{OH}$ ; (d) at once seps. as a milky turbidity quickly changing to a cryst. ppt. *Iodoacetylsalicylamide*, decomp. 138–9°. [*Diethylaminoacetyl*]salicylamide *hydrochloride*, obtained in 85% yield from 5 g. (d) in  $\text{Me}_2\text{CO}$  allowed to stand some hrs. with 3.5 g.  $\text{NHEt}_3$ , then treated with a little  $\text{Et}_2\text{O}$  to complete the pptn. of  $\text{NHEt}_3\text{HCl}$ , filtered and made acid to Congo with alc.  $\text{HCl}$ , m. 195–6°; free base, seps. with 0.5 mol.  $\text{H}_2\text{O}$ , m. 144–5°. The  $\text{HCl}$  salt in  $\text{H}_2\text{O}$  containing a little  $\text{HCl}$  gives with concd.  $\text{NaNO}_2$  a white ppt. whose m. p. varies somewhat in different preps., the highest observed being 110°. It seems to consist chiefly of the nitrite contaminated with more or less of the free base; its soln., on warming or long standing, partially decomp. with formation of green tars and partially hydrolyzes with deposition of the base.

CHAS. A. ROUILLER.

**Fluorides of organo-metallic compounds. I. Triaryltin fluorides and dialkyltin difluorides.** ERICH KRAUSE. Techn. Hochschule, Berlin. *Ber.* 51, 1447–56(1918).—Unlike the chlorides, bromides and iodides, the triaryltin fluorides are solids, odorless, with very high m. ps., subliming before melting, distinctly sol. in  $\text{H}_2\text{O}$  with acid reaction, very difficultly sol. in indifferent org. solvents ( $\text{C}_6\text{H}_6$ ,  $\text{Et}_2\text{O}$ ), more easily in alcs. and  $\text{AcOH}$ . Likewise the dialkyltin difluorides melt very high, are almost insol. in indifferent org. solvents, slightly sol. in  $\text{EtOH}$ , more in  $\text{MeOH}$  and  $\text{H}_2\text{O}$  (with acid reaction); with neutral alkali fluorides they form sol. double salts. The trialkyl compds. can be obtained quant. by treating solns. of the hydroxides (*C. A.* 12, 1883) with aq.  $\text{HF}$  and crystg. the resulting ppts. from hot  $\text{EtOH}$ ; they sep. in felted, doubly refracting prisms which become strongly electrified on rubbing. They are more conveniently prepd. by treating the other halides in alc. with excess of aq. neutral  $\text{KF}$ . This reaction is reversible; on treating the fluorides with concd.  $\text{KCl}$ ,  $\text{KBr}$  or  $\text{KI}$  the unpleasant odors of the  $\text{Cl}$ ,  $\text{Br}$  and  $\text{I}$  compds. soon develop; by gently warming with the fuming halogen acids this reverse change can be made quant. The dialkyl difluorides are obtained almost quant. in the same way with the exactly calcd. amts. of alkali fluorides and sep. from  $\text{MeOH}$  in cryst. powders of fine, thin, doubly refracting needles, which do not become markedly electrified on rubbing. These compds. are very useful in prepg. mixed Sn tetraalkyls as they react energetically with alkylmagnesium halides, and also in sepg. trialkyltin halides from the tetraaryl compds. by shaking the concd.  $\text{Et}_2\text{O}$  solns. of the latter with neutral aq.  $\text{KF}$  and alc. The soly. values given below represent the amts. in g. sol. in 100 g.  $\text{MeOH}$ ,  $\text{EtOH}$ ,  $\text{H}_2\text{O}$  and  $\text{C}_6\text{H}_6$ , resp. The m. ps. (in sealed tubes) are cor. *Trimethyltin fluoride*, does not change in a sealed tube up to 360°, then begins to turn brown and blackens and shrinks together about 375°; soly. 2.45, 1.08, 0.846 and 0.05 at 31.3°. *Triethyltin fluoride*, begins to sublime above

180°, m. in a sealed tube 302°, soly. 4.39, 2.20, 0.182 and 0.034 at 32.2°. *Tripropyltin fluoride*, m. 275°, soly. 4.26, 2.73, 0.020 and 0.118 at 31.3°. *Triisobutyltin fluoride*, m. 244°, soly. 0.614, 0.414, 0.012 and 0.100 at 31.6°. *Triisooamyltin fluoride*, m. 288°, soly. 1.22, 1.03, 0.003 and 0.967 at 31.3°. *Diethylpropyltin fluoride*, from  $\text{Et}_3\text{SnPr}$  in  $\text{CHCl}_3$  treated with Br and then shaken with aq. KF, m. 271°, soly. 6.93, 3.78, 0.12 and 0.05 at 31.0°. *Dimethyltin difluoride*, decomps. above 360°, soly. 0.33, 0.081 and 4.66 in MeOH, EtOH and  $\text{H}_2\text{O}$  at 30.7°. *Diethyltin difluoride*, seps. from MeOH in quadratic plates or elongated rhombic tables with varying amts. of solvent, m. around 229° (uncor.); after 1 hr. at 110° *in vacuo* over  $\text{P}_2\text{O}_5$  it sinters about 240° and m. 287–90° (depending on the rate of heating), soly. 2.64, 0.45, 2.03 and 0.047 at 30.8°; 0.1 mol. treated with warm neutral KF until a clear soln. results (almost exactly 0.2 mol. KF is required), then with 5 times this amt. of KF and then concd. to incipient crystn., yields on cooling the double salt  $\text{Et}_2\text{SnF}_2 \cdot 2\text{KF}$  in leaflets. *Dispropyltin difluoride*, sinters 200°, m. 204–5° (uncor.), sol. 1.91, 0.93 and 0.22 in MeOH, EtOH and  $\text{H}_2\text{O}$  at 32°.  $\text{Et}_3\text{SnPr}$ , from  $\text{Et}_3\text{SnF}$  and  $\text{PhMgCl}$ ,  $b_{11}$  82°, shows  $d_4^{18.6}$  1.1710,  $n_D^{18.6}$  1.47065, 1.47410, 1.48249, 1.48965 for  $H_\alpha$ , D,  $H_\beta$  and  $H_\gamma$  at 16.6°. The (iso-Am) $\text{Sn}$  prepd. in the usual way from  $\text{SnCl}_4$  and iso-AmMgCl and purified by treating with aq. neutral KF and alc.  $b_m$  188° (uncor.),  $d_4^{18.6}$  1.0353,  $n_D^{18.6}$  1.46946, 1.47242, 1.47989, 1.48607 for  $H_\alpha$ , D,  $H_\beta$  and  $H_\gamma$  at 16.0°. CHAS. A. ROULLER.

**Luminescence phenomena in pyrazoline derivatives.** FRITZ STRAUS, with CARL MUFFAT and W. HEITZ. Univ. Strassburg i. Els. *Ber.* 51, 1457–77 (1918); cf. Auwers and Voss, *C. A.* 4, 586.—The reaction whereby 1-phenylpyrazolines are obtained by the action of  $\text{PhNHNH}_2$  on certain aromatic ketones, owing to the extraordinary ease with which the hydrazones first formed rearrange, has been extended to a number of substituted ketones and hydrazines.  $\text{PhCH:CHCOCH:CHPh}$  reacts in this way, so that adopting Auwers' scheme of classification,  $\text{PhCH:CHCOR'}$ , the grouping  $\text{PhCH:CH}$  falls in with aromatic and sec. or tert. aliphatic residues in favoring ring closure. The  $\alpha$ - and  $\beta$ -naphthylhydrazones form the pyrazolines as easily as the Ph compds.  $\text{NO}_2$  groups in the  $p$ -position in the hydrazine residue and  $o$ - but not  $p$ -MeO groups in the ketone Ph residues make the ring closure more difficult. Halogens do not markedly hinder the pyrazoline formation as long as they are present only in the ketone or the hydrazine residue, but if present in both they render the hydrazones quite stable. These pyrazoline compds. show vivid fluorescence under the influence of Röntgen rays, almost as intense as that of  $\text{BaPt(CN)}_4$  in some cases, and not only in the solid state but in soln. also, depending to a marked degree on the nature of the solvent; the alc. and AcOH solns. become only faintly luminescent while in  $\text{CS}_2$ ,  $\text{C}_6\text{H}_6$  and  $\text{CHCl}_3$  the phenomenon is surprisingly intense. The compds. also show vivid fluorescence in diffuse daylight. The fluorescence produced in these 1,3,5-substituted pyrazolines by Röntgen rays differs from that produced by daylight, however, in that it is limited to those compds. in which an unsatd. residue (Ph or CO) is substituted in positions 3 and 5; where the limit for the daylight fluorescence lies has not been detd. with certainty but as fluorescence of simple pyrazolines is nowhere mentioned, it is probably produced by a Ph group in position 1. The hydrazones first formed, which have been isolated in some cases, are intensely colored, even more so than their isomeric pyrazolines, but show no fluorescence. The pyrazoline ring, however, is not in itself the seat of the fluorescence phenomenon; the cyclic compds. resulting from the phenylhydrazones of cinnamylideneacetophenone and dicinnamylideneacetone, which do not contain a pyrazoline ring, also fluoresce under the influence of Röntgen rays. The intensity of the fluorescence depends on the nature of the substituents, increasing in the order below with the following substituents in positions 1, 3 and 5, resp.: Ph, Ph, Ph; Ph,  $p\text{-Me}_2\text{NC}_6\text{H}_4\text{CH:CH}$ ,  $p\text{-Me}_2\text{NC}_6\text{H}_4$ ; Ph,  $\text{PhCH:CH}$ , Ph; Ph,  $p\text{-ClC}_6\text{H}_4$ .

$p\text{-ClC}_6\text{H}_4$ ; Ph,  $p\text{-MeOC}_6\text{H}_4\text{CH:CH}$ ,  $p\text{-MeOC}_6\text{H}_4$ ; Ph,  $p\text{-ClC}_6\text{H}_4\text{CH:CH}$ ,  $p\text{-ClC}_6\text{H}_4$ ;  $p\text{-BrC}_6\text{H}_4$ ,  $p\text{-ClC}_6\text{H}_4\text{CH:CH}$ ,  $p\text{-ClC}_6\text{H}_4$ .  $\text{O}_2\text{NC}_6\text{H}_4$  in position 1 destroys the fluorescence under the rays but not in daylight;  $1\text{-}\alpha\text{-}$  and  $\beta\text{-C}_{10}\text{H}_7$  derivs. fluoresce. This fluorescence under Röntgen rays is not limited to these pyrazolines, however; it is found, partly in conjunction with ordinary fluorescence, in Ph-substituted ethylenes, butadienes and hexatrienes; the Ph-substituted acetylenes show it faintly;  $\text{Ph}_3\text{CH}$  very brightly; CPh, not at all; anthracene and retene very faintly; *ms*-dibromoanthracene intensely; hydrocollidinedicarboxylic ester quite strongly. The constitutions of the following hydrazones and pyrazolines were detd. by the methods of A. and V. 1,5-Diphenyl-3-styrylpyrazoline,  $\text{PhN.N:C(CH:CHPh).CH}_2\text{CHPh}$ , m.  $147\text{--}8^\circ$  (Minunni,

*Gass. chim. ital.* 29, II, 398(1899)), evapd. to dryness with 2%  $\text{KMnO}_4$ , gave  $\text{BzOH}$  and 1,5-diphenylpyrazole-3-carboxylic acid, needles from  $\text{H}_2\text{O}$ , m.  $183^\circ$ ; the pyrazoline is unchanged by Na-Hg and by boiling with  $\text{AcOH}$ ; it dissolves in  $\text{H}_2\text{SO}_4$  with golden yellow color and gives with  $\text{FeCl}_3$  a green color changing to blue. *1- $\alpha$ -Naphthyl-3-styryl-5-phenylpyrazoline*, obtained by filtering a hot soln. of 5 g.  $\alpha\text{-C}_{10}\text{H}_7\text{NHNH}_2\text{HCl}$  and 2.7 g. KOAc in 200 g. abs. alc. from the pptd. KCl, boiling 1 hr. with 5 g.  $(\text{PhCH:CH})_2\text{CO}$  in 100 cc. alc., then 0.5 hr. longer with charcoal, filtering, concg. *in vacuo* to 0.5 its vol., pouring off the alc. after cooling and drying *in vacuo* over  $\text{H}_2\text{SO}_4$ , yellow needles with green fluorescence from abs. alc. containing some  $\text{AcOEt}$ , m.  $164^\circ$ .  *$\beta$ -Isomer*, yellow, felted needles with faint green fluorescence from  $\text{AcOEt}$ , m.  $195^\circ$ . *1-p-Bromophenyl-3-styryl-5-phenylpyrazoline*, from 4 g.  $(\text{PhCH:CH})_2\text{CO}$  allowed to stand 2 days with 5 g.  $p\text{-BrC}_6\text{H}_4\text{NHNH}_2$  in 20 cc.  $\text{AcOH}$ , yellow needles with green fluorescence from  $\text{AcOEt}$ , m.  $177^\circ$ , sol. in  $\text{H}_2\text{SO}_4$  with dirty green color changing to deep green on addition of  $\text{FeCl}_3$ , unchanged by Na-Hg or boiling  $\text{AcOH}$ . From 4.5 g.  $(\text{PhCH:CH})_2\text{CO}$  boiled 3 hrs. with 3 g.  $p\text{-O}_2\text{NC}_6\text{H}_4\text{NHNH}_2$  in alc. and a little  $\text{AcOH}$  and allowed to stand several days is obtained *dibenzalacetone p-nitrophenylhydrazone*, yellow-red leaflets from  $\text{C}_6\text{H}_6$ , m.  $173^\circ$ , sol. in  $\text{H}_2\text{SO}_4$  with red-yellow color; 1.7 g. in 20 cc.  $\text{AcOEt}$  and 10 cc.  $\text{AcOH}$  reduced with 60 g. Na-Hg gave 0.5 g. crude solid  $p\text{-C}_6\text{H}_4(\text{NH}_2)_2$ , while boiling 1 hr. in 20 parts  $\text{AcOH}$  converts it into *1-p-nitrophenyl-3-styryl-5-phenylpyrazoline*, yellow-red crystals with intense green fluorescence from  $\text{AcOEt}$ , m.  $204\text{--}5^\circ$ , sol. in  $\text{H}_2\text{SO}_4$  with red-violet color hardly changed by  $\text{FeCl}_3$ . *o,o'-Dimethoxydibenzalacetone phenylhydrazone*, brown-yellow warts from alc., m.  $142^\circ$ , reduced by Na-Hg in  $\text{EtOH-AcOH}$  to  $\text{PhNH}_2$  and rearranged by boiling  $\text{AcOH}$  into *1-phenyl-3-o-methoxystyryl-5-o-methoxyphenylpyrazoline*, light yellow crystals from alc. (in which they form a soln. with green-blue fluorescence), m.  $153\text{--}4.5^\circ$ , sol. in  $\text{H}_2\text{SO}_4$  with red-yellow color changed to blue by  $\text{FeCl}_3$ , gives no  $\text{PhNH}_2$  with Na-Hg. *1-Phenyl-3-p-methoxystyryl-5-p-methoxyphenylpyrazoline*, from 5 g. dianisalacetone and 5 g.  $\text{PhNHNH}_2$ , boiled 2 hrs. in 50 cc.  $\text{C}_6\text{H}_6$ , white-yellow leaflets (appearing almost green from their intense fluorescence) from  $\text{AcOEt}$ , m.  $159^\circ$ ; it is more easily obtained by boiling the ketone and hydrazine 5 min. in 10 parts  $\text{AcOH}$ . *1-Phenyl-3-p-dimethylaminostyryl-5-p-dimethylaminophenylpyrazoline*, yellow needles with extraordinarily intense green fluorescence from  $\text{AcOEt}$ , m.  $192^\circ$ . *o,o'-Dichlorodibenzalacetone*, obtained in rather poor yield by boiling 5 g.  $o\text{-ClC}_6\text{H}_4\text{CHO}$  and 1 g.  $\text{Me}_2\text{CO}$  in 60 cc. alc. 15 min. with 3 cc. of 5% NaOMe. yellow needles from MeOH, m.  $125^\circ$ ; *p-bromophenylhydrazone*, dark yellow, crystals from MeOH, m.  $145^\circ$ . *1-Phenyl-3-o-chlorostyryl-5-o-chlorophenylpyrazoline*, yellow needles from alc. (the soln. shows green fluorescence), m.  $145^\circ$ , sol. in  $\text{H}_2\text{SO}_4$  with yellow-green color turned dark by  $\text{FeCl}_3$ , unchanged by boiling  $\text{AcOH}$ . *1-Phenyl-3-p-chlorostyryl-5-p-chlorophenylpyrazoline*, fine, yellow needles with strong green fluorescence from  $\text{AcOEt}$ , m.  $212^\circ$ , gives no  $\text{PhNH}_2$  with Na-Hg, gives so faint a reaction with  $\text{FeCl}_3$  in  $\text{H}_2\text{SO}_4$  as not to reveal the presence of a pyrazoline. *p,p-Dichlorodibenzalacetone*

*p*-bromophenylhydrazones, from 5 g. of the ketone and 3.5 g. of the hydrazine shaken 3 days, protected from the light, in 50 cc. AcOH yellow needles from  $C_6H_6$ , m.  $183^\circ$ , stable only in  $H_2$ , quickly turns brown in the air, sol. in  $H_2SO_4$  with yellow color changed transiently green, then brown, by  $FeCl_3$ , reduced by Na-Hg in EtOH-AcOH to *p*- $BrC_6H_4NH_2$  and converted by boiling AcOH into *1-p*-bromophenyl-3-*p*-chlorostyryl-5-*p*-chlorophenylpyrazoline, yellow needles with intense green fluorescence from alc., m.  $173-4^\circ$ , sol. in  $H_2SO_4$  with yellow color changed to deep green by  $FeCl_3$ , unchanged by Na-Hg. Methyl 1-phenyl-3- $\beta$ -carbomethoxyvinylpyrazoline-5-carboxylate,  $PhN.N:C(CH:CHCO_2Me).CH_2.CHCO_2Me$ , from  $CO(CH:CHCO_2Me)_2$  and  $PhNHNH_2$ ,  
 $\text{PhN.N:C(CH:CHCO}_2\text{Me).CH}_2\text{.CHCO}_2\text{Me}$

in boiling  $C_6H_6$ , yellow leaflets with green fluorescence from AcOEt, m.  $153^\circ$ , sol. in  $H_2SO_4$  with red-yellow color changed to dark blue by  $FeCl_3$  (yield rather poor), unchanged by boiling AcOH. Ethyl ester, yellow leaflets with green fluorescence, m.  $92.5^\circ$ , hydrolyzed by aq. alc. NaOH on the  $H_2O$  bath to the free dicarboxylic acid, yellow needles, m.  $204^\circ$  (decompn.); Pb salt, yellow, finely granular ppt. Dimethyl ketopentadienedicarboxylate phenylmethylhydrazone, from the ester and the hydrazine in AcOH at  $40^\circ$ , dark red, refractive crystals from MeOH, m.  $105^\circ$ . Diethyl ester *p*-bromophenylhydrazone, deep red-yellow needles from MeOH, m.  $134^\circ$ . From 5 g. of A. and V.'s  $PhCH:CHCH:CHC:(NNHPh)Ph$  boiled 1 hr. with 20 cc. AcOH is obtained an isomer (a), probably  $PhN.N:CPh.CH:CH.CH_2.CHPh$  or  $PhN.N:CPh.CH_2.CH:CH.CHPh$ ,  
 $\text{PhN.N:CPh.CH:CH.CH}_2\text{.CHPh}$  or  $\text{PhN.N:CPh.CH}_2\text{.CH:CH.CHPh}$

warts with faint fluorescence from AcOH, m.  $123-4^\circ$ , sol. in  $H_2SO_4$  with green-blue color changed to green by  $FeCl_3$ , while the hydrazone dissolves with yellow color changed to brown by  $FeCl_3$ ; Na-Hg gives no  $PhNH_2$  but resinifies the substance.  $PhCH:CHCH:CHC:(NNHPh)Me$  dissolves in  $H_2SO_4$  with red-yellow color changed to dirty green by  $FeCl_3$ , yields  $PhNH_2$  with Na-Hg and is converted by boiling AcOH into an oil strongly fluorescing in  $C_6H_6$  and whose red-yellow soln. in  $H_2SO_4$  is turned blue-red by  $FeCl_3$ , while Na-Hg gives no  $PhNH_2$ .  $(PhCH:CHCH:CH)_2O$  and  $PhNHNH_2$  heated in AcOH and then in alc. give orange-yellow needles from alc. and AcOEt, m.  $142^\circ$  (Diel and Einhorn, *Ber.* 18, 2325 (1885), describe a "phenylhydrazone" as m.  $155^\circ$ ), dissolves in  $H_2SO_4$  with orange-red color changing to blue on standing 10 sec. or adding  $FeCl_3$ , gives no  $PhNH_2$  with Na-Hg but is resinified, is unchanged by AcOH. Evidently the substance is not a hydrazone but a cyclic compd. analogous to (a) above. On oxidation with  $KMnO_4$ , BzOH was the only product which could be isolated.

CHAS. A. ROULLER.

The ester acids of  $\alpha,\alpha'$ -dimethylcinchomeronic acid. RUD. WEGSCHIEDER. Univ. Wien. *Ber.* 51, 1478-9(1918); cf. Mumm and Hüneke, *C. A.* 12, 1878.—M. and H. prepd. the isomeric mono-Et esters of the acid, one by half-sapon. of the di-Et ester with HCl or KOH, the other by the action of alc. on the anhydride, and concluded that the former is the  $\beta$ -ester on the ground that the sterically non-hindered  $CO_2Et$  is much more easily attacked; likewise they assume that steric hindrance plays a part in the formation of the second from the anhydride and consider the method of formation a confirmation of the  $\gamma$ -position of the  $CO_2Et$  group. Their conclusion from the half sapon. may be considered as quite probable, although instances are known where the more strongly hindered  $CO_2H$  group is chiefly attacked on half-sapon., and therefore only the  $\gamma$ -structure remains for the other ester, but its constitution cannot be derived from the fact that it is formed from the anhydride, for W. has shown that in such cases it is generally not steric hindrance but the strength of the  $CO_2H$  group which has the greatest influence, the alkyl going to the more strongly acid group. But in this case, even his rule cannot serve in detg. the constitution of the ester formed from the anhydride, for the relative strengths of the  $CO_2H$  groups in a di- $CO_2H$  acid containing

N cannot be predicted with certainty, in the majority of cases, including the present one, owing to the complications arising from the formation of inner salts, etc.

CHAS. A. ROUILLER.

**Molecular rearrangements. XIII. Phenyl migrations.** P. J. MONTAGNE. Univ. Leiden. *Ber.* 51, 1479-88(1918); cf. *C. A.* 4, 2821.—The results of the present investigation confirm those reported in the earlier papers and also those of other workers that when there is an intramol. migration of a Ph group the latter is attached before and after the rearrangement through the same C atom, *i. e.*, the substituents remain in the same positions so that it is perfectly justifiable, *e. g.*, to deduce the structure of the benzophenones from the rearrangement products of their oximes. Thus the oxime, m. 151.5°, of (*p*-BrC<sub>6</sub>H<sub>4</sub>)<sub>2</sub>CO, whose structure has been established beyond doubt (*C. A.* 9, 2533), gives with PCl<sub>5</sub> in Et<sub>2</sub>O a *bromobenzobromoanilide*, BrC<sub>6</sub>H<sub>4</sub>CONHC<sub>6</sub>H<sub>4</sub>Br, m. 223.5°, which with alc. KOH in sealed tubes on the H<sub>2</sub>O bath yields *p*-BrC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>, m. 63°, and *p*-BrC<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H, m. 254°, so that in the rearrangement product, just as in the original oxime, both Br atoms are in the *p*-positions. Hoffmann's (IC<sub>6</sub>H<sub>4</sub>)<sub>2</sub>CO, for which he assumed the *p,p'*-structure without proof (*Ann.* 264, 165(1891)) (by working in sunlight, M. has succeeded in increasing the yield from 4.5 to 18%; his product b<sub>12</sub> 281°, m. 238.5°), yields on rearrangement of its oxime, m. 173°, *p*-iodobenz-*p*-iodoanilide, m. 287°, the structure of which is proved by its synthesis from *p*-IC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub> and *p*-IC<sub>6</sub>H<sub>4</sub>COCN in Et<sub>2</sub>O; therefore, by the rule of Ph migration, the phenone really has the *p,p'*-structure assumed by H. This is further proved by nitrating it with cold HNO<sub>3</sub> (d. 1.5); this gives 4,4'-diiodo-3,3'-dinitrobenzophenone, yellow crystals from C<sub>6</sub>H<sub>6</sub>, m. 185.5°, for with alc. NH<sub>3</sub> at 150° it yields the known [4,3-H<sub>2</sub>N(O<sub>2</sub>N)-C<sub>6</sub>H<sub>4</sub>]<sub>2</sub>CO, m. 293°.

CHAS. A. ROUILLER.

**Acetylation of 4-iodoaniline by acetic anhydride.** P. J. MONTAGNE. Univ. Leiden. *Ber.* 51, 1489-92(1918).—*p*-IC<sub>6</sub>H<sub>4</sub>NO<sub>2</sub>, light yellow crystals from AcOEt, b<sub>77</sub> 289°, m. 174°, is obtained in 95% yield by v. Baeyer's method; when 25 g. in 250 cc. Me<sub>2</sub>CO is treated with 75 g. crystd. SnCl<sub>2</sub> and 75 cc. HCl (d. 1.19), allowed to stand 15 min., treated with H<sub>2</sub>O and an excess of KOH, freed from Me<sub>2</sub>CO on the H<sub>2</sub>O bath and allowed to stand overnight, it gives 80% *p*-IC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>, m. 62.75°. When 5 g. are boiled 15 min., 2.5 hrs. or 6 hrs. with 50 cc. Ac<sub>2</sub>O, there are obtained a mixt. of IC<sub>6</sub>H<sub>4</sub>NHAc, m. 184.5°, and *p*-iododiacetanilide, m. 108.5°; if the mixt. of IC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub> and Ac<sub>2</sub>O is gently warmed (not boiled) until all dissolves and at once poured into H<sub>2</sub>O, only the mono-Ac deriv. is formed. In all these expts. the alc. soln. of the ppt. formed when the Ac<sub>2</sub>O soln. is poured into H<sub>2</sub>O deposits on cooling small amts. of glittering platelets, m. 204.5°, which were obtained in too small amt. for further investigation. The mono-Ac compd. boiled 6 hrs. with 10 parts Ac<sub>2</sub>O gives the di-Ac deriv. The latter boiled 2 hrs. with 1:5 H<sub>2</sub>SO<sub>4</sub> is hydrolyzed to IC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>.

CHAS. A. ROUILLER.

**Solubilities, separation, and purification of anthracene, carbazole and phenanthrene.** JOHN M. CLARK. *J. Ind. Eng. Chem.* 11, 204-9(1919).—Methods for the purification of carbazole and anthracene are given together with the relative solubilities of anthracene, carbazole and phenanthrene in 14 organic solvents. Some general information relative to crude coal tars is included.

STEWART, ALFRED W.: *Recent Advances in Organic Chemistry*. 3rd Ed. London: Longmans, Green & Co. 350 pp. 14s. net. For review see *Chem. Trade J.* 64, 97(1919) or *Pharm. J.* 102, 44(1919).

**Dehydrating pyridine.** C. R. DOWNS. U. S. 1,290,124, Jan. 7. Pyridine containing  $H_2O$ , *e. g.*, 15%  $H_2O$ , is mixed with sufficient  $C_6H_6$  to give a proportion, by weight, of 10.325 to 1 of  $C_6H_6$  to  $H_2O$ . In this proportion, the  $C_6H_6$  and  $H_2O$  form a binary mixt. which boils constantly at about  $69.5^\circ$ . The mixt. of  $C_6H_6$ ,  $H_2O$  and pyridine then subjected to fractional distn., preferably in a column still with collection of 3 fractions, *vis.*, below  $80^\circ$ ,  $80-115^\circ$  and above  $115^\circ$ . When the distn. is thus conducted, the first fraction contains nearly all the  $H_2O$ , the second fraction contains substantially all the remainder of the  $H_2O$ , some  $C_6H_6$  and a small amount of pyridine bases, and the last fraction contains substantially all the pyridine and pyridine bases. The process may be somewhat simplified by distg. in two fractions only, in which case a first fraction is obtained consisting of  $H_2O$  and  $C_6H_6$  and a second fraction containing pyridine or pyridine bases. The first fraction (b. below  $80^\circ$ ) seps. into 2 layers; a lower aq. layer (containing only about 0.2% of the pyridine bases so that it may be discarded) and an upper  $C_6H_6$  layer containing a larger proportion of pyridine bases. This upper layer may be added to the next batch for further distn. to recover the pyridine bases from it. The second fraction, containing very little  $H_2O$  mixed with  $C_6H_6$  and some pyridine, is returned to the still for the next distn. to recover the pyridine which it contains. The last fraction consists of pyridine or pyridine bases nearly free from  $H_2O$ . As a preliminary treatment of the pyridine, containing  $H_2O$ , it may be mixed with either  $C_6H_6$  or a satd. NaCl soln. and  $C_6H_6$  and shaken and then allowed to settle to effect sepn. of an aq. layer before distg.

**1,2,4-Methylhydroxyisopropylbenzene.** R. H. MCKEE. Can. 188,518, Feb. 4, 1919. 1,2,4-Me(OH)(Me<sub>2</sub>CH) $C_6H_3$  is produced by sulfonating "spruce turpentine," forming an alkali metal salt of the resulting acid, fusing the salt with caustic alkali, dissolving the resulting mass and neutralizing the resulting alk. soln.

**Carbazole.** SOC. D'ECLAIRAGE CHAUFFAGE ET FORCE MOTRICE. Brit. 121,455, Oct. 7, 1918. Crude carbazole is purified by dissolving it in a phenol (phenol, cresols, xlenols) and crystg. out. The crystals are washed with a phenol and the process is repeated, giving a product of 90% purity. The process may be applied to the crude carbazole contained in the pyridine solns. from the purification of anthracene by pyridine, or to the crude carbazole obtained by decomp. K carbazole produced in purifying anthracene by KOH.

**Acetic acid from acetaldehyde.** S. UTHEIM. Norw. 29,011, Aug. 12, 1918.  $CH_3CHO$  is treated with an oxidizing gas under pressure, the reacting substances being introduced separately into a restricted reaction chamber in limited quantities, so that the oxidizing gases can act only on small quantities of the acetaldehyde at any one time.

The photochemical effect of certain fluorescent substances on rennin. JANET HOWELL CLARK. *Am. J. Physiol.* 47, 251-64 (1918).—Fluorescent materials have a destructive effect on rennin in sunlight because they are decomposed by light of certain wave lengths yielding toxic substances.

J. F. LYMAN.

**Penetration of antiseptics into solid media.** P. CARNOT AND J. DUMONT. *Compt. rend. soc. biol.* 81, 1199-1200 (1918).—C. and D. propose the following technic for studying the penetration of antiseptics into solid media *in vitro*: Liquid gelose con-

taining suitable nutrient substances is poured into a Petri dish so as to form a rather thick layer. A hollow cylinder of glass or porcelain with a series of indentations in the circumference of the lower opening is placed in the center of the mass before the latter solidifies. After the gelose has solidified a const. amt. of an aq. soln. of the antiseptic to be studied is poured into the cylinder. The Petri dish and contents are placed in an incubator immediately or after several hrs. and the contents are examd. 24 hrs. afterward. The antiseptic diffuses into the gelose and bacterial growth is found to occur only in the periphery of the gelose mass, thus leaving a clear, sterile circle, the diam. of which (expressed in mm.) gives a numerical comparison of the sterilizing value of the various antiseptics studied. In the case of certain antiseptics ( $\text{AcOH}$ ,  $\text{HgCl}_2$ ) the colonies which constitute the circumference of this circle are less numerous but more luxuriant and chromogenic than those occurring in the peripheral part of the gelose mass; this result is due to the favorable action of these antiseptics when present in small, optimum concn. Addition of formic acid or  $\text{AcOH}$  to solns. of  $\text{HgCl}_2$ ,  $\text{NaF}$ ,  $\text{Cu}$  salts, etc., greatly increased the penetration of the latter into gelose. By means of these expts. it may be possible to obtain an idea of the relative degree of penetration of various antiseptics into wounds.

## B. METHODS AND APPARATUS.

STANLEY R. BENEDICT.

The determination of tyrosine in proteins. CARL O. JOHNS AND D. BREESE JONES. U. S. Dept. Agr., Bur. Chem. *J. Biol. Chem.* 36, 319-22(1918).—The figures obtained by the colorimetric method of Folin and Denis (*C. A.* 6, 3433) for the % of tyrosine in proteins are probably more accurate than those obtained by direct isolation as it is practically impossible to crystallize out all of the tyrosine from the hydrolysates of most proteins. The hydrolysis of the protein with 20%  $\text{HCl}$  should not be continued longer than 12 hrs. since tyrosine is slowly decomposed by boiling  $\text{HCl}$ . Tryptophan is completely decomposed during the hydrolysis and the decompn. products do not interfere with the colorimetric detn. of tyrosine. Oxyproline does not interfere with the detn. and hydrolysates of gelatin, which contains up to 6% of oxyproline, gave but little color with the reagent; this color was probably due to tyrosine in the gelatin since a test for tyrosine was obtained with Millon's reagent.

A. P. LOTEROP.

The quantitative determination of phosphorus by the nephelometric method. EDWARD B. METCS. U. S. Dept. Agr., Bur. Animal Ind. *J. Biol. Chem.* 36, 335-46 (1918).—In the quant. detn. of phosphorus by the nephelometric method, temp. and the character of the strychnine molybdate reagent as detd. by its age and by other factors are matters of the greatest importance. Very large deviations from what may be called the theoretical readings may be caused by the character of the reagent and by the amt. of  $\text{HCl}$  present at the time the phosphate suspensions are made. When the strychnine molybdate reagent is prepared according to the directions given by Kober and Egerer (*C. A.* 9, 2855), the stability and other important qualities of the reagent depend, to a surprizing extent, on the strength of the  $\text{HCl}$  used in prepg. it and this concn. must be known with great exactness. Com.  $\text{HCl}$  advertized on the bottle to contain 37% generally contains only about 35% and differences of this order in the

concn. of the HCl used produce very marked differences in the character of the strychnine molybdate reagent. If the densities of phosphate suspensions are to be calcd. from their nephelometric values by means of mathematical formulas as suggested by Kober and Egerer, a different formula will be required for every different reagent used when "1 to 1" (by volume) HCl is employed in prep. the reagent and also for every different density of the standard suspension. In prep. the strychnine molybdate reagent, "the greater the concn. of HCl present when the strychnine sulfate is added, the greater will be the amt. of material pptd. at that time and the greater will be the stability of the reagent. Reagents made up with strong HCl, however, tend to minimize the differences in nephelometric value as between phosphate solns. of different densities; none of the reagents that are serviceable when used in the procedure described by Bloor are entirely stable; they all tend to form a spontaneous ppt. and to reach a state in which they show no difference in nephelometric value as between phosphate suspensions of different densities. The temp. at which the strychnine sulfate is added to the  $\text{Na}_2\text{MoO}_4$ -HCl soln. in making up the reagent may have a considerable effect on its character. In spite of the many disturbing factors, the nephelometric method can be used satisfactorily by taking certain precautions. It is practically an invariable rule (in M.'s experience) that, whatever the relation between difference in density and difference in nephelometric value, less dense solns. read against denser ones in the nephelometer always show a lower nephelometric value. One method, therefore, of escaping from the difficulties which have been described is to have on hand enough of the test soln. for several detns. It is well also to have a series of standard phosphate solns. of graded concns., the range of which should extend from the lower to the upper limit of the range within which the concn. of the test soln. might lie. The test is first read against that standard which is guessed to be nearest to it; and, under ordinary circumstances, this preliminary reading should make it possible to pick out a standard for a second confirmatory reading, whose difference from the test will lie very close to the limits of accuracy attained in any ordinary chem. work. It is necessary, also, however, to test the reagent frequently by using it to read two moderately different standard solns. against each other. For if, as is commonly the case with old reagents and with reagents made up with strong HCl, the differences in nephelometric value are strongly minimized, the experimenter may be deceived in the preliminary test into thinking that the standard and test solns. have nearly equal concns., when this is really not the case at all. In M.'s experience, it has been necessary to test the reagent in the manner described at least every other day. It is obvious that when the detns. are carried out as described above, one is more likely to be deceived by a reagent that minimizes the nephelometric differences than by one that exaggerates them. But reagents which greatly exaggerate the nephelometric differences are likely to be very unstable. Those reagents are likely to be most serviceable which give nephelometric readings about equal to what they should be theoretically. This condition is approx. attained for the Bloor procedure in summer (in the vicinity of Washington) by using a 1:1 HCl which contains 19% HCl by wt. When the temp. is lower, it is advantageous to use a 1:1 HCl which contains from 17 to 18% HCl by wt."

A. P. LOTHROP.

**Notes on Folin's direct nesslerization method for the determination of nitrogen.** LOVELL LANGSTROTH. Univ. Cal. Hosp. *J. Biol. Chem.* 36, 377-80(1918).—On account of the impurity of the  $\text{H}_2\text{SO}_4$  now purchasable as c. p., it is necessary to make a correction for the color modification due to digestion or to digest the standard  $(\text{NH}_4)_2\text{SO}_4$  soln. as follows: Measure 1 cc. of a soln. of purified  $(\text{NH}_4)_2\text{SO}_4$  (containing 1 mg. of N per cc.) with a calibrated Ostwald pipet into a large hard-glass test-tube, add 1 cc. of the acid mixt. of Folin and Denis (*C. A.* 10, 2906) and digest for 2 min. with

a very low flame, placing a watch glass over the top of the tube when  $\text{H}_2\text{SO}_4$  fumes begin to come off. Cool, add distd.  $\text{H}_2\text{O}$ , wash into a flask and set aside until the urine or blood filtrate has been similarly treated. Complete the procedure as directed by Folin and Denis. When metaphosphoric acid is used as the protein precipitant in the detn. of the non-protein N of blood, it is impossible to conc. the soln. when the hard-glass test-tube is held in a vertical position on account of bumping. "If the tube is held just far enough from the horizontal to bring the surface of the liquid half way between the bottom and the mouth of the tube, the microburner flame adjusted so as to be not over  $\frac{3}{4}$  in. high with the tip of the flame 1 cm. from the lowest portion of the tube, and moved away from the center line of the tube toward the edge, as in Fig. 1,

Fig. 1.

the fluid will boil without loss by bumping or foaming. Over 30 min. will usually be required to boil the 10 cc. of filtrate down to 2 cc. but the tube need not be watched more than occasionally. When blackening begins the tube is turned upright and the remainder of the procedure carried out as in the case of urine. At this point, however, the precaution should be taken of placing the tip of the flame well over to one side; otherwise bumping and loss will occur. While keeping it in contact with the tube the flame should at the same time be lowered as far as is consistent with the continued digestion of the blackening filtrate; otherwise there

will be too great a loss of  $\text{H}_2\text{SO}_4$  fumes and a consequent solidification of the material in the tube as digestion is completed. With the greatest care at the end of digestion solidification will sometimes occur and ruin the detn. by making it difficult to wash the material quant. into a flask. This can be prevented by raising the watch crystal slightly on one side and cautiously introducing distd.  $\text{H}_2\text{O}$  with a capillary pipet and rubber nipple drop by drop down the side of the tube as soon as blackening disappears and the soln. clears. Sputtering but no loss of material will occur. The remainder of the procedure is carried out as directed by Folin." With these modifications the method for the detn. of total N of the urine and non-protein N of the blood by direct Nesslerization is accurate and effects a great saving of time and reagents.

A. P. LOTHROP.

**The determination of urobilin in urine.** S. MARCUSSEN and SVEND HANSEN. Rigshospitalet, Univ. Copenhagen. *J. Biol. Chem.* 36, 381-9(1918); cf. *C. A.* 12, 1064.—By the diln. tests described it is possible to est. sufficiently near for clinical use the amt. of urobilin present in the urine of patients suffering from liver complaints. The 10% suspension of  $(\text{AcO})_2\text{Zn}$  in abs. alc. used by Schlesinger is not satisfactory as a coarse, cryst., monoclinic  $(\text{AcO})_2\text{Zn}$  is formed within a few days which is very difficult to shake up and which ppts. quickly. Measure 10 cc. of urine into test-tube A and add 3 drops of a 5% alc. soln. of I (to oxidize any urobilinogen present to urobilin). Shake and measure 1 cc. into test tube B. To test tube A, containing 9 cc. of urine, add 9 cc. of abs. alc. and 1 g. of  $(\text{AcO})_2\text{Zn}$  and, after soln. is complete, filter through a 9 cm. filter paper into a test tube 16 mm. in diam. (diln.  $\frac{1}{2}$ ). If the soln. fluoresces in daylight falling from behind the observer, add to test tube B 3 cc. of  $\text{H}_2\text{O}$ , 1 cc. of a clear 20% aq. soln. of  $(\text{AcO})_2\text{Zn}$ , and 5 cc. of abs. alc. Filter after mixing (diln.  $\frac{1}{10}$ ). If the filtrate fluoresces, measure out 5 cc. of urine and add to it 5 cc. of  $\text{H}_2\text{O}$  and 2 drops of I soln. Transfer 1 cc. of the mixt. to another test-tube (16 mm. diam.), add 3 cc. of  $\text{H}_2\text{O}$ , 1 cc. of 20% aq.  $(\text{AcO})_2\text{Zn}$  soln. and 5 cc. of abs. alc. Mix and filter (diln.  $\frac{1}{20}$ ). If the filtrate fluoresces, measure 5 cc. of urine drop by drop into 15 cc. of  $\text{H}_2\text{O}$

containing 2 drops of I soln. Take 1 cc. of this mixt. and proceed as in the preceding test (diln. 1/40). In a number of patients suffering from liver complaints the fluorescence was detectable in dilns. of 1/40 to 1/80 and in certain cases in even greater diln. In normal patients a fluorescence in a diln. of 1/10 was occasionally observed so that a diln. of 1/20 should be considered as the lowest limit for a pathologically increased urobilinuria. Ammoniacal urines must be acidified with AcOH before making the test. Highly acid urines should be made alk. with  $\text{NH}_4\text{OH}$  and then acidified with AcOH. Further expts. are contemplated "on the importance of the concn. of the urine, the contents of pathological components, the variations in the quantity of the substances usually present, the importance of food, and the consumption of alc." A. P. L.

A method for the identification of certain uramino acids in the presence of amino acids and urea. ALICE ROHDE. Univ. Cal. Med. School. *J. Biol. Chem.* 36, 467-74 (1918).—In the proposed method urea is eliminated from the material under investigation by decomp. it with urease and traces of uramino acids are detected by a special application of the Van Slyke gasometric method for the detn. of amino-N. Treat the fresh urine with Jack bean urease in such proportions as to decompose the urea in 15 min. at 37°, or when possible make the collections directly into enzyme solns. at that temp. Test a portion to make sure that all the urea has been decompd. Neutralize with  $\text{H}_3\text{PO}_4$  and add an excess. Ext. in a liquid extn. app. for 6 or more hrs. with 4-6 vols. of AcOEt. Dist. the AcOEt with steam, clarify the aq. residue with charcoal and conc. on a water bath to small vol. Filter off any crystals of uramino acids which sep. and identify by the m. p. and by amino N detns. before and after treatment with boiling HCl (which forms the anhydrides of the uramino acids which give off no amino N). If no crystals sep. and it is desired to detect traces of uramino acids, continue the concn. until a very small amt. of sirup remains. Add 1-2 cc. of  $\text{H}_2\text{O}$ , make alk. with N NaOH and filter if necessary. Boil for 1 min. to drive off traces of  $\text{NH}_3$  and make up to vol. in a 10 cc. flask. Carry out the Van Slyke method for amino-acid N on 2 cc. samples. Shake second samples for 1 min., allow to stand for 1 hr. in the reaction chamber and shake a second time for 3 min. If more amino N is found in the second sample than in the first, acidify a 5 cc. portion of the material with 10 drops of concd. HCl and boil under a reflux condenser for 1 hr. Make alk., transfer to a 10 cc. flask and make up to vol. Det. the amino N as usual. The difference between the amino N figure before boiling with HCl and that after boiling may be assumed to be amino N from uramino acids.  $\alpha$ -Ureido- $\beta$ -phenylpropionic acid added to cat urine and  $\alpha$ -ureidobutylic acid injected intravenously were recovered by the method. No preformed uramino acid could be demonstrated in the urine of a cat after intravenous injection of 6 g. of *dl*-phenylalanine. A. P. LOTHROP.

A source of error in the use of picric acid in colorimetric estimations in biological fluids. ALICE ROHDE AND MARION SWEENEY. Univ. Cal. Med. School. *J. Biol. Chem.* 36, 475-7 (1918).—"A chromogenic substance other than sugar is present in the blood which certain picric acid fails to ppt. Solid picric acid after purification may undergo a change in its pptg. value for chromogenic substances in the blood. The formation of a deeper color on addition of alk. to picric acid solns. as tested by Folin does not account for the discrepancy of certain picric acids in blood sugar detns. The pptg. value of picric acid must be detd. before reliance may be placed upon color production in quant. procedures for blood sugar." A sample of picric acid which failed to bring about pptn. in the usual way was one which had been purified by the method of Folin and Doisy and kept for 10-12 months in a dark closet in a colorless bottle with a little moisture. A. P. LOTHROP.

A method for the estimation of potassium in blood. S. W. CLAUSEN. Washington Univ. Med. School. *J. Biol. Chem.* 36, 479-84 (1918).—The cobaltic nitrite method

has been adapted to the detn. of K in small amts. of organic materials. The  $K_2NaCo(NO_2)_6$  is heated with dil. NaOH and the nitrites are estd. by titration with dil.  $KMnO_4$  soln. *Reagents.* *Na cobaltic nitrite reagent:* A.  $Co(NO_2)_2$ , 50 g.; glacial AcOH, 25 cc.; distd.  $H_2O$  to 100 cc. B.  $NaNO_2$ , 100 g.; distd.  $H_2O$  to 200 cc. Mix 6 parts of A and 10 parts of B and pass a rapid current of air through the soln. for several hrs. to remove the oxides of N. Keep the dark brown fluid on ice for 2 days and filter off the yellow ppt. which forms on account of the traces of K and  $NH_4$  in the reagents. If kept in a dark bottle in an ice box, the reagent will keep for several weeks.  *$KMnO_4$  soln.:* Dil. 0.1 N  $KMnO_4$  to about 0.02 N and boil under a funnel reflux condenser for 2-3 hrs. After 1-2 days, decant from the Mn oxides and preserve in a cool, dark place. *Standard K solns.:* Standard A, 1 cc. = 10 mg. K. KCl, 9.546 g.; concd. HCl, 1 cc.;  $H_2O$  to 500 cc. Standard B, 2 cc. = 1 mg. K. Standard A, 25 cc.; concd. HCl, 1 cc.;  $H_2O$  to 500 cc. The KCl should be recrystd. several times and then fused; the HCl is added to prevent the growth of molds. *Estn. of K in pure solns.:* Measure an amt. of soln. which contains 0.2 to 2.5 mg. of K into a 50 cc. beaker and evap. almost to dryness on a water bath. Add 2-3 drops of glacial AcOH and 1 cc. of the Na cobaltic nitrite reagent. Evap. until the mixt. becomes sirupy, taking care not to carry the evapn. too far which results in the formation of insol. brown compds. giving too high results. Cool and add 4-5 cc. of  $H_2O$ . Prepare a Gooch crucible having a fairly thick asbestos mat (filter paper must not be used) and just before the mat is sucked dry pour on a suspension of  $BaSO_4$  which serves to fill up the larger pores and also as an excellent test for the mat. Before the  $H_2O$  has all passed through, pour on the contents of the beaker containing the ppt. Rinse the beaker with 4-5 cc. of cold  $H_2O$  and repeat the washing 6 times with 2-3 cc. portions of  $H_2O$ . When the mat is almost dry, transfer it to the beaker and wash all adhering particles from the crucible to the beaker with 9-10 cc. of  $H_2O$ . Add 1 cc. of 10% NaOH soln., heat to boiling, then cool. Make up the dark brown mixt. to exactly 25 cc. and centrifuge. Pipet off 20 cc. into a 150 cc. Erlenmeyer flask, add 5 cc. of 1:4  $H_2SO_4$ , and titrate with 0.02 N  $KMnO_4$  soln. Run in the  $KMnO_4$  until a faint pink color persists for  $\frac{1}{2}$  min. Warm the flask on an elec. plate and add more  $KMnO_4$  slowly until the color persists for  $\frac{1}{2}$  min. at about  $70^\circ$ . Blanks are usually small, 0.05 to 0.1 cc. The K value of the  $KMnO_4$  soln. is detd. by analysis of standard soln. B and this value should be detd. frequently. *Calcns.* are based on the values thus obtained rather than on a theoretical factor. *Estn. of K in blood:* Digest 2 cc. of plasma or 1 cc. of blood with 5 cc. of a mixt. of 1 part of  $H_2SO_4$  and 20 parts of  $HNO_3$  in a  $200 \times 25$  mm. Pyrex glass tube. Arrange a fume absorber and heat slowly with a micro-burner for about  $\frac{1}{2}$  hr. A short piece of Pt wire sealed through the bottom of the tube, serving as a heat-conductor and boiling focus, is useful in preventing foaming and bumping. After  $\frac{1}{2}$  hr. evap. off the excess of  $HNO_3$  rapidly. The remaining drop of  $H_2SO_4$  will darken considerably. Remove the flame and allow the small amt. of  $HNO_3$  condensed on the walls of the tube to run back. If the soln. does not clear, add 2-3 drops of  $HNO_3$  and boil until the acid is colorless. Cool, wash into a 50 cc. beaker, make alk. to phenolsulfonethalein with 10% NaOH and evap. to dryness on a water bath. Add glacial AcOH (a few drops) until the mixt. is acid, then 1 cc. of cobaltic nitrite reagent and evap. until crystals of  $Na_2SO_4$  appear. Cool. Complete the detn. as already described for pure solns. All reagents must be tested for the presence of K. A sample of NaOH purified by alc. was found to contain as much as 0.05% of K. The Na citrate used to prevent clotting of the blood must also be examd. for K. A few results obtained with plasma and whole blood in a variety of pathological conditions are given.

A. P. LOTHROP.

Conductivity as a measure of permeability. W. J. V. OSTERHOUT. Harvard Univ. *J. Biol. Chem.* 36, 485-7(1918).—O. has used the method of measuring the

permeability of protoplasm by detg. the elec. conductivity of the tissues. A considerable part of the current must flow through the non-living intercellular substances by which the masses of protoplasm are sepd. in the tissue, and O. has investigated the question as to whether any of the current passes through the living protoplasm. Expts. made with a green marine alga (*Ulva*) and a marine flowering plant (*Zostera*), plants whose intercellular substance consists of cellulose, in which the protoplasm was killed by means which are known to produce no irreversible changes in the properties of cellulose, indicate "that the alterations of conductivity observed in living tissue are due to changes in the protoplasm and not to changes in the non-living intercellular substance." The protoplasm was killed by various means such as partial drying, treatment for a few hrs. with 25% alc., exposure for a few min. to sea water at 40° and placing for several hrs. in a soln. of NaCl of the same conductivity as the sea water, and in all cases the conductivity rose to a const. value (indicating death) and was not thereafter affected by exposure to reagents which produce great alterations in the conductivity of living tissue. The temp. coefficient of the elec. conductivity of living tissue differs from that of dead tissue which could not be the case if the living protoplasm did not conduct part of the current. The results obtained by the elec. method are in complete agreement with those obtained by other methods of measuring permeability, such as that of tissue tension, plasmolysis, exosmosis and diffusion through membranes of living tissue. "It is, however, more accurate as well as more convenient. It enables one to make detns. at much shorter intervals than other methods. This not only permits the detection of rapid changes in permeability which would otherwise escape observation, but enables one to det. with precision the time curve, which is indispensable in the study of dynamics."

A. P. LOTHROP.

A method of measuring the electrical conductivity of living tissues. W. J. V. OSTERHOUT. Harvard Univ. *J. Biol. Chem.* 36, 557-68(1918).—A method is described for measuring the elec. conductivity of living organisms which can be applied to pieces of tissue or to intact organisms. The material is placed between two electrodes and its elec. resistance measured by means of a Wheatstone bridge. Measurements made by the method do not vary more than 1% from the mean under the most favorable circumstances. The original must be consulted for the description of the app. and the details of the technic.

A. P. LOTHROP.

A quantitative study of the evaporation of blood serum. GEORGE H. BURROWS AND EDWIN J. COHN. Harvard Univ. and Med. Dept., U. S. Army. *J. Biol. Chem.* 36, 587-90(1918).—"A need for the dried solids of blood serum in immediately sol. form has led to a study of methods of low temp. evapn. of protein solns. The method adopted may be used in other instances." Freshly collected blood is allowed to clot undisturbed in cylindrical vessels of several gallons cap. The strands of the clot are sepd. from the sides with a thin knife blade and then the serum is syphoned into bottles and centrifuged to remove the remaining corpuscles. Laking of the blood is thus rendered unnecessary and a perfectly clear, amber-colored liquid is obtained. The liquid is evapd. in an ordinary distg. flask of a cap. of at least 1 l. which is provided with 100 g. of rather large glass pearls. The flask is weighed when quant. data are desired. It is then immersed to about the level of the side tube in H<sub>2</sub>O of the desired temp. (usually not above 50°). A dropping funnel is introduced into the flask with the end of the stem extending well into the bulb. The side tube is connected with an efficient condenser, arranged vertically and emptying into a previously weighed bottle of a size suitable for trapping the evapd. and recondensed H<sub>2</sub>O. After this follows in succession a small, weighed CaCl<sub>2</sub> tower, a manometer and a vacuum pump. The trap bottle and CaCl<sub>2</sub> tower are immersed in ice water which also flows through the condenser jacket. The app. is evacuated to a pressure of 1 cm. or less of Hg and a weighed amt. of serum is

allowed to enter slowly through the dropping funnel at a rate as nearly as possible equal to the rate of evapn. The serum foams vigorously and leaves a friable product adhering loosely to the walls of the flask. When the desired amt. of liquid has evapd., the cold  $H_2O$  in the condenser is replaced with warm and the air is slowly admitted through the funnel after which the flask is again evacuated. The temp. of the bath is raised somewhat as the evapn. nears completion. When the serum is dry, the app. is dismantled and the parts previously weighed are dried and reweighed. The glass pearls will loosen and pulverize the product if the flask is given a vigorous rotary motion and are sepd. from the product by pouring onto a sieve of proper mesh. Very accurate results can be obtained. The solids of the serum examd. constituted 8.93% of the whole. The powdered product was light yellow in color and had a faint odor. It contained 11.75% of N and dissolved readily in distd.  $H_2O$ , giving a very slightly turbid soln. The trapped  $H_2O$  from the evapn. was clear and colorless and was nearly free of electrolytes as it had a sp. conductance of approx.  $7.7 \times 10^{-5}$ . It had a slight odor of  $NH_3$  and was faintly alk., having a  $p_H$  of 8.1. The  $p_H$  of the original serum, which had not been adjusted to a particular  $CO_2$  tension, was 7.65 and its conductance  $1.22 \times 10^{-2}$ . Redissolved in  $CO_2$ -free  $H_2O$  in its original concn., the reaction of the prepn. was  $p_H$  9.4. The isoelec. point of serum albumin appears at about  $p_H$  4.7 and if serum is treated with approx. 0.06 cc. of  $N$  HCl per 1 cc., giving a  $p_H$  of 4.5, and then evapd., the product obtained is more friable and less sol. in  $H_2O$  than that from the untreated serum. Such a prepn. is presumably near the isoelec. point of the proteins and dissolves readily on the addition of acid or of alk. A prepn. prepared from serum treated with less acid than the above requirement ( $p_H$  5.3) was more easily sol. in  $H_2O$  than that from serum evapd. at its isoelec. point and less alk. than that from unacidified serum. The carbonates of the serum can thus be conveniently transformed into chlorides or into the salts of other acids.

A. P. LOTHEROP.

**New method for detection of methylene blue in urine and approximate determination of the amount of this substance eliminated in twenty-four hours.** C. BOTELHO. *Compt. rend. soc. biol.* 81, 291-3(1918).—This method is based on the adsorption of certain dissolved pigments by collodion films immersed in a soln. of the same. The method may be used as a qual. test by adding AcOH to the urine, heating to boiling (to transform chromogen, if present), immersing the films in the urine and withdrawing the latter after about 10 min.; the color is made more apparent by superimposing the films and very small amts. of methylene blue may thus be rendered distinctly visible. This method is more sensitive than the usual  $CHCl_3$  method and is fully as sensitive as the thymol procedure (recently described by Tribondeau). An approx. quant. detn. may be made in the following manner in cases where renal permeability is to be tested: A no. of collodion films of standard dimensions is prepared by pouring 5 cc. of recently prepd. officinal collodion on each of a no. of  $9 \times 12$  cm. glass slides so as completely to cover the latter with a layer of collodion of approx. uniform thickness. After evapn. is complete the films are detached and used as needed or kept in  $H_2O$  until required. One-fifteenth of the total 24 hrs. urine is heated to boiling after addition of AcOH,  $1/2$  of a film is introduced and the boiling is continued 10 min.; if all the methylene blue is not adsorbed another  $1/2$  of a film is introduced and the procedure is repeated. Expts. with pathol. urines and various solns. of methylene blue of different concns. showed that a collodion film of given dimensions adsorbs a practically const. amt. of methylene blue and that thirty  $9 \times 12$  cm. films are required in order to adsorb 25 mg. of this substance, this being the amt. usually eliminated by normal kidneys during a 24-hr. period following intramuscular injection of 50 mg. of methylene blue. Two films are, therefore, required in order to adsorb all the methylene blue eliminated under these conditions in  $1/18$  of the total 24 hrs. urine. In cases of imperfect renal perme-

ability the approx. proportion of the normal amt. of methylene blue which is eliminated in a 24-hr. period may be detd. by successively adding  $\frac{1}{2}$  of a film, as indicated above, until all of the dye is adsorbed.

H. S. PAINE.

**Determination of the nuclein content of yeast.** C. A. LUBSEN. Amsterdam. *Pharm. Weekblad* 55, 1625-8(1918).—Expts. were made to find whether nucleins are completely pptd. by digestion with pepsin HCl in solns. containing more than 0.1% of HCl. It has been contended that part of the nuclein remains in soln. owing to formation of nucleic acid, which is sol. in acid soln. But the results obtained lead to the conclusion that nucleic acid formation does not take place under the conditions of analysis, and that the detns. are, therefore, reliable.

### C. BACTERIOLOGY.

The effect of concentrated solutions of certain magnesium salts on pyrogenic and other bacteria. ZAE NORTHRUP. Mich. Agr. College, East Lansing. *J. Infect. Dis.* 24, 170-6(1919).—The purpose of this paper is to explain the rationale of the use of a concd. soln. of  $MgSO_4$  in cosmetics for the removal of pimples from the face. The beneficial effect of this soln. is shown not to be due to any bactericidal action on *Staphylococcus aureus*. *Streptococcus* skin infections, however, may be inhibited if any concn. of  $MgSO_4$  be used externally.  $MgCl_2$  had a most marked inhibitory action on the growth of all organisms experimented with (*Staph. aureus*, *B. coli*, *B. typhosus*, *Ps. pyocyaneus*), which suggests that it may be substituted for  $MgSO_4$  under certain conditions.

Catalase and oxidase content of seeds in relation to their dormancy, age, vitality and respiration. WILLIAM CROCKER AND GEORGE T. HARRINGTON. Bur. Plant Industry, U. S. Dept. Agr. *J. Agr. Research* 15, 137-75(1918).—By the method of Appleman (C. A. 5, 897) measurements were made of the catalase activity of the seeds of Johnson grass, Sudan grass and *Amaranthus reflexus* under varying conditions of drying, age, heating, retention in a germinator and germination. Measurements were also made of the catalase activity of the different parts of the seed in the above-mentioned plants and also in wheat, Tunis grass, sorghum and peach seeds. The oxidase activity was also measured for a number of the above-mentioned plants by the method of Bunzell (C. A. 6, 2445). In detg. the catalase activity it was found that the  $H_2O_2$  used should be neutral, as acidity in this reagent greatly inhibits the catalase activity. Excess

pulverization also reduced the catalase activity. The powdered seed of Johnson grass stored in a desiccator lost 70% of its activity in 54 days while the intact seeds do not show this rapid loss. In all cases the catalase activity of the embryo was many times that of the endosperm while the physiologically inactive organs showed much lower catalase activity than the seeds. Immature seeds showed a greater catalase activity than the mature seeds. With the exception of the seeds of basswood, seeds which were dried after storage in the germinator showed a great decrease in catalase activity. In relation to storage and heat, the seeds of Johnson grass were labile while the seeds of *Amaranthus* were stable. The seeds which have a period of "after-ripening" showed a marked rise in catalase activity when retained in the germinator imbibed, while under similar conditions the seeds of Johnson grass lost 66% of their catalase activity in 1 year and showed a smaller decrease in their oxidase activity. During germination the catalase activity of grass seeds rose rapidly with no change in oxidase content. Johnson grass seeds exhibited a relationship between catalase activity and respiratory intensity.

R. N. HARGER.

General introduction to the study of the physiological function of the latex in *Hevea brasiliensis*. W. BOBILIOFF. *Arch. v. d. Rubbercultuur* 2, 281-313; *Chem. Weekblad* 15, 1393-4(1918).—The theories which have been advanced to explain the function of the latex in rubber-producing plants are reviewed. None of these have been thoroughly established. The theories that it is a plant food, a water reservoir or an absorbent for O are more probable than that it is a food carrier or a simple secretion. The conclusion reached is that the latex performs more than one function.

JULIAN F. SMITH.

The behavior of some organic compounds in plants. X. G. CIAMICIAN AND C. RAVENNA. Bologna. *Gazz. chim. ital.* 48, I, 253-304(1918).—The expts. described in preceding papers (C. A. 12, 1307, 1308) are continued in this. The paper is divided into 3 parts. *Part I. The action of some compds. on the germination and the development of the plant:* The earlier expts. on the effect of various org. compds. on kidney beans germinated and grown on absorbent cotton were extended. Many other substances and some other plants have now been used. From the expts. which are fully described it is clear that some aromatic substances like benzyl and salicyl alcs., benzoic and salicylic acids, vanillin and tannin are supported quite well by the plants of kidney beans, without causing notable changes in their exterior form. Eugenol and essence of mustard are, however, quite poisonous as was foreseen; mandelic nitrile is less poisonous and produces a characteristic change in the habit of the plant, which, however, does not persist. More interesting results were obtained with the alkaloids, and above all with nicotine, by experimenting on kidney beans with 1 part per 1000 solns. of the resp. tartrates. All the vegetable alkaloids properly examd. exercise a poisonous action on the plants, while pyridine and piperidine produce only a darker color in the leaves, not affecting growth and development. The comparison of the behavior of caffeine, xanthine and uric acid is interesting. The 1st is a distinct poison for kidney bean plants while with xanthine and uric acid used as K salts there is a normal sturdy growth without any injury. Caffeine is trimethylxanthine. Thus the presence of Me groups gives rise to an intense physiological action which the parent compd. does not have. It has been held by some that the alkaloids are useless org. excrement and that the Me group so frequently encountered in plant products ought to be considered as a protective agent to damp the too reactive groups like hydroxyl and imino groups. These expts. reverse this view. A further study of the behavior of org. compds. and their alkyl derivs. with plants appears to be promising. Among the alkaloids tested the least poisonous for the kidney bean plant is morphine, which has remarkably slight toxic effects; this is followed by quinine which causes the base of the stem to wither after which

the plant bends and dies; then strychnine which at first shows a favorable action, but presently causes the leaves to fall by which the plant perishes. The antagonistic action between strychnine and mandelic nitrile is remarkable. It was observed before with germinating seeds and now with plants that the plant lives longer when subjected to a mixt. of the two than in the presence of either of the two. Nicotine has a strongly toxic action on kidney bean plants grown in glass which it kills in a few days. C. and R. briefly discuss the idea that alkaloids may function in plants like vegetable hormones and suggest that simple compds. like pyridine may be used to produce the more complex alkaloids just as tyrosine is utilized to produce adrenaline in the suprarenal gland. The results are summarized in tables. *Part II. Autooxidation:* The earlier expts. on this subject have been extended to other compds. in the presence of air and  $\text{CO}_2$ . The results are summarized in tables. The main conclusion, on the basis of the comparative tests in the air and in  $\text{CO}_2$ , is that the disappearance of certain compds. in an atm. of  $\text{O}_2$  in the presence of the enzymes of spinach leaves is really due to a process of oxidation. Saligenin in a  $\text{CO}_2$  atm. is converted into a polyanhydride salyretin and this transformation takes place more quickly with spinach hash than with that from apples (mele). EtOH and mannitol are not appreciably oxidized and are likewise not autooxidizable by light. It is remarkable that acetaldehyde, which is little autooxidizable in an atm. of  $\text{O}_2$ , is not changed appreciably by these org. catalysts, while acetone, which is autooxidizable in light, is oxidized in the presence of the enzymes to formic and acetic acids. Of the 3 amino acids used glycol, alanine and asparagine only the last is oxidized in air, while it remains unchanged in an atm. of  $\text{CO}_2$ . Cinnamic acid is not oxidized at the double bond as one might suspect, but remains mostly unchanged; a trace only is transformed into the isomer isocinnamic acid. It is curious that this isomerization does not take place in an atm. of  $\text{CO}_2$ . Of the alkaloids tested caffeine and strychnine remain unchanged, while morphine, quinine and cinchonine are largely oxidized. The enzymes in spinach leaves also bring about other reactions; thus glucose in air is largely oxidized; but in a  $\text{CO}_2$  atm. a considerable amt. of a substance that gives glucose on hydrolysis is formed. Both in air and  $\text{CO}_2$  tartaric acid gives a complex which is hydrolyzed by emulsin to give tartaric acid. Since salicylic acid and saligenin are not autooxidized in the light it will be useful to compare in further expts. the catalytic action with light with that of plant enzymes in oxidations. *Part III. Elimination of certain compds. from the aerial organs of plants:* In some preceding work it was found that some compds. that remain unchanged in contact with spinach hash in a current of  $\text{O}_2$  disappear largely when inoculated into the living plant. This was observed with pyridine and nicotine. This difference in behavior might be due to a greater power of oxidation of the living plant in comparison with ground leaves, but since in this case volatile compds. are involved the elimination of these alkaloids through the leaves is not excluded. In order to test this, some expts. on the inoculation of corn with these 2 compds. were carried out. The expts. showed that pyridine thus administered is largely eliminated from the leaves. The aerial part of the plant was placed in a closed flask fitted with 0.5%  $\text{H}_2\text{SO}_4$  to catch the pyridine. The recovery was not quant. so that it is possible that the plant oxidizes or transforms otherwise some of the pyridine administered. Similar results were obtained with nicotine. E. J. WITZEMANN.

Metabolism of glucose in surviving organs. V. Action of the renal tissue of

the fed or fasting dog on glucose circulating therein. U. LOMBROSO. Univ. Rome. *Arch. farm. sper.* 25, 12-6(1918); cf. *C. A.* 12, 1309.—Blood or Ringer soln. containing glucose, when circulated through the isolated kidney, undergoes an appreciable loss of glucose. With kidneys from fasting dogs the diminution is less than with kidneys from fed dogs. VI. Influence of fasting on the ability of the intestine to consume glucose circulating therein. CARLO LUCHETTI. *Ibid* 57-64.—Glucose dissolved in Tyrode solution or blood and circulated in the intestinal tissue of the fed dog diminishes 50% or more. Part is destroyed and part is deposited as glycogen. Similarly with intestinal tissue from the fasting dog there is a diminution of glucose but to a smaller extent. Fasting does not, however, influence the glycolytic power of the intestine to the extent that it does in the liver and kidney. A. W. DOX.

Net energy values of alfalfa hay and of starch. HENRY P. ARMSBY AND J. AUGUST FRIES. Penn. Agr. Expt. Sta. *J. Agr. Research* 15, 269-86(1918); cf. *C. A.* 12, 2211.—Seven respiration calorimeter expts. were carried out with a steer to det. the digestibility and metabolizable energy of different amts. of alfalfa hay and of a mixt. of alfalfa hay and starch. The digestibility of the ration, the losses in the urine and the extent of methane fermentation increased as the total amt. of ration was decreased, and the greater loss of energy in urine and methane more than compensated for the smaller losses in feces so that the total metabolizable energy was less on light rations. The metabolizable energy of starch was 10% greater than found by Kellner (*Land. Vers. Sta.* 53, 474(1900)) and the av. heat increment from starch was 1.692 cal. per kg. as against 1.248 as found by Kellner; while the av. heat increase for alfalfa hay was 999 cal. per kg. R. N. HARGER.

Three year tests for the comparison of a relatively high with a relatively low protein ration with dairy cattle ("Frühjahrskalbinnen") in the stall. J. J. OTT DE VRIES. *Vereeniging tot exploitatie eener proefzuivelboerderij te Hoorn Jahresbericht* 1916, p. 15; *Biedermanns Zentr.* 47, 165-9(1918).—A relatively considerable diminution (20 to 30%) of the protein ration with reference to the av. norms of Kellner gave no distinctly noteworthy decrease in the output of "Frühjahrskalbinnen" in the fall, caused only a small decrease in the yield of milk as well as of the most important constituents of the milk of freshly calved cows and showed also subsequently no distinct decrease of yields during the first month of pasturage upon the meadow. During the spring stall-period those cows which received more protein gave increases of protein in their milk of less than 10% of the increased protein in their food. ALBERT R. MERZ.

The large-scale development of swine fattening in Hungary. K. EREKY. Buda-pest. *Mitt. Deut. Landw. Ges.* 32, 541-50(1917); *Biedermanns Zentr.* 47, 180-8(1918).—A description is given of a large establishment for fattening swine and of the problems involved in the improvement of the business. The swine is compared to a machine converting feed into bacon. The efficiency of the bacon-producing organism is 37%. The increase of this efficiency is a scientifically and practically important goal. The formation of fat from dextrose is formulated thus:  $13\text{C}_6\text{H}_{12}\text{O}_6 = \text{C}_{56}\text{H}_{104}\text{O}_6 + 23\text{CO}_2 + 26\text{H}_2\text{O}$ , so that theoretically 270 parts of sugar give 100 parts fat. Actually only a 100 kg. increase in live wt. is obtained from 400 kg. sugar. Fat formation does not always take place in the same way. Fatty acids are often formed from the starch through bacterial activity. These are more easily converted into fat than the dextrose. E. believes that well fed swine live in symbiosis with the bacteria which convert starch into fatty acids. Amino-acids play a leading role as transition stages in the protein-formation of the swine. A table is shown giving the various amino-acid decomposition products of plant proteins. Some of these amino-acids are indispensable while others are not necessary for the swine. Supplementing the food with inorg. salts is also necessary. Analyses are given of the ash of corn and barley. The pre-

dominant potash content causes a lack of Na in the blood and it is necessary to supply the swine with NaCl. The physiological action of Ca is emphasized. Whether a swine is of peaceful or restless temperament depends upon the relation between the secretions of various glands to the blood and fat production is in turn dependent on this. The internal secretions apparently are derived from the amino-acids of proteins. The carboxyl-group of the acids is split off in the glands and the so-called "proteinogenen" amines are formed (Abelin, Über proteinogene Amine, *Naturwissenschaften* 1917, No. 12).

ALBERT R. MERZ.

Feeding experiments with raw and boiled carrots. MINNA C. DENTON and EMMA KOHMAN. Univ. Chicago. *J. Biol. Chem.* 36, 249-63 (1918).—"It has often been urged that some of the common root vegetables should be used as extensively as may be practicable, as partial substitutes for the cereals, as supplements to them in certain respects, and certainly as supplements to the vegetable oils. A knowledge of the dietetic properties of these root vegetables is then of importance, particularly so since the use of dehydrated vegetables promises to come into general vogue." Carrot in the dry form furnishes almost as large a proportion of N cals. as compared with total cals. as does corn meal and is then equiv. to the latter quant. Feeding expts. with albino rats have been performed to det. whether carrots are also qual. sufficient for growth and well-being. The nutritive value of carrots when used as part of a mixed diet is not perceptibly injured by the ordinary methods of cooking. Much of the cal. value is, however, lost when the H<sub>2</sub>O used in the cooking is not added to the food. On a diet properly supplemented with starch, purified com. casein, butter or lard, and salts to such an extent that 50% of the cal. value of the diet is furnished by carrots, normal growth and reproduction occur in albino rats. Animals may be supported in good health for as long as 16 weeks on an exclusive diet of carrots except for the addition of Ca, P, Na and Cl; there is no growth on this diet but an increase in body wt. may occur. Results on this exclusive carrot diet are inconstant on account of the great variation in the nutritive value of different lots of carrots and in the vitality of different animals. Considerable amts. of both H<sub>2</sub>O-sol. and fat-sol. vitamins are present in carrots. When the proportion of N is reduced by the addition of fat or starch, dropsy occurs in a large % of the rats fed on a carrot diet. "War dropsy," which has appeared among the victims of malnutrition during the war, has been generally ascribed to a lack of fat but D. and K. are inclined "to attach at least equal if not greater importance to the protein or N content of the diet." Further work on this problem is in progress.

A. P. LOTHROP.

The synthetic capacity of the mammary gland. I. Can this gland synthesize lysine? E. B. HART, V. E. NELSON AND W. FITZ. Univ. Wis. *J. Biol. Chem.* 36, 291-307 (1918).—"The mammary gland manufactures "a special protein, casein, and presumably from amino-acid fragments in the blood. It is also presumed that it makes casein, not through synthesis of amino-acids *de novo*, but by an orderly assembling, in quant. relations, of those amino-acids found in the casein mol. Should an amino-acid, occurring in casein and essential for growth, be absent in the diet, would there be a serious interference in casein building, or does this gland retain special synthetic powers not shown by muscle cells, and in the absence of a sp. amino-acid make it from other nitrogenous fragments?" In investigating the cap. of the mammary gland to synthesize the lysine necessary for the production of casein, vigorous female rats were fed on zein diets made complete by properly supplementing with a complete salt mixt., vitamins and tryptophan and in some expts. arginine and histidine. The effect of this diet was compared with the effect of the same diet to which lysine had been added in amt. to form 1% of the diet. Those animals on a lysine-free diet were invariably unable to rear their young although a number of animals

gave birth to apparently normal litters, indicating that the other was able to build her young presumably from tissue reserves rather than through synthesis of lysine. In only a single instance was a litter nursed sufficiently to carry it beyond a mere maintenance of life for approx. 2 weeks. What milk was secreted was undoubtedly normal rat's milk, the lysine contained in the milk proteins made being furnished through tissue catabolism. When lysine was added to the supplemented zein diet not only were normal litters of young born but in most instances the young were successfully nursed. There was not a normal rate of growth but the condition of the mother and young was healthy; the probable cause of the failure of the young to grow at a normal rate was the incomplete absorption of the zein in the ration. Normal growth occurred when casein was substituted for the supplemented zein-lysine combination in the diet. When additions of arginine and histidine were made to the zein-lysine ration, the rate of growth was no greater; apparently the indigestibility of the zein counteracted any beneficial effect those two amino-acids might have been expected to have when added to a protein relatively low in them. In a majority of cases the animals did not even maintain their live wt. on the lysine-free diet and showed evidences of malnutrition such as rough and soiled coats and a nervous and excitable condition. In the opinion of the authors "normal maintenance is not possible in the absence of the amino-acid, lysine." In previous expts. where conclusions were drawn from records of maintenance of live wt., "there certainly is the possibility that catabolizing non-essential tissues can furnish over very long periods of time enough lysine for rehabilitation of those tissues more essential for the maintenance of life. The maintenance of live wt. may be either a replacement of loss with  $H_2O$  or with fat. Milk secretion, like growth, is ultimately dependent upon the quality and quantity of amino-acids ingested with the food."

A. P. LOTHEOP.

**Animal calorimetry. XV. Further experiments relative to the cause of the specific dynamic action of protein.** H. V. ATKINSON AND GRAHAM LUSK. Cornell Univ. Med. College. *J. Biol. Chem.* 36, 415-27(1918); cf. *C. A.* 6, 3432; 7, 107, 108, 363, 364, 1041; 8, 2563; 9, 1630, 2926; 12, 285, 1999.—The validity of L.'s conclusions that the sp. dynamic action of protein is due to the action of the metabolites ( $\alpha$ -hydroxy- and  $\alpha$ -keto-acids) of certain of the amino acids in the protein (*C. A.* 9, 1631) and that the process of deamination or of urea formation plays no role in the increased heat production has been further investigated with the following results: The administration of 200 cc. of 0.4% HCl may cause a slight increase of 6% in the basal metabolism of a dog but the simultaneous administration of 10 g. of aspartic acid causes no further increase. "The expts. with aspartic acid corroborate the former work with glutamic acid and indicate that the 2 dibasic acids occurring in protein exert no sp. dynamic action upon metabolism. Asparagine and glycocoll, which contain the same % of N behave very differently in metabolism, the 1st being without sp. dynamic action and the other exerting the most powerful sp. dynamic action of any of the amino-acids contained in protein which have thus far been tested. Therefore, the sp. dynamic action of protein is not due to the  $NH_2$  radical of the amino-acid mol. Succinic acid (a possible intermediary metabolite of glutamic acid) is without power to increase the heat production, which accords with the previously detd. behavior of glutamic acid. Acetamide (a chem. isomer of glycocoll) is not deaminized by the dog nor does it increase the heat production of the animal. The conclusion formerly expressed that the processes of deamination and urea formation have nothing to do with the sp. dynamic action of protein is upheld by these later researches." The expts. wholly fail to substantiate Grafe's conclusions (*Deut. arch. klin. Med.* 118, 1) that the sp. dynamic action of protein is largely due to the liberation of the  $NH_2$  radical of amino-acids.

A. P. LOTHEOP.

Urinary excretion of phosphates in the rabbit. FRANK P. UNDERHILL AND L. JEAN BOSSERT. Yale Med. School. *J. Biol. Chem.* 36, 521-30(1918).—The expts. were undertaken to study "the relative proportions of P of the food intake excreted in the urine when the diet varied from acid-producing food, such as grain, to base-producing food, like carrots; to note the effect of subcutaneous injections of phosphates on the urinary P of the rabbit; and to observe the influence of diets consisting of acid-producing or base-producing foods and of injections of mono-, di-, and tribasic phosphates upon the relative proportion of injected P excreted in the urine. Rabbits, in contrast to most other herbivora, excrete a considerable amt. of phosphates through the kidneys. The proportion of food P eliminated in the urine by rabbits may be caused to vary widely by changes in the nature of the diet, being about 25% on a carrot diet, 50% on a mixed diet of carrots and oats, and over 100% on a diet composed exclusively of oats. Solns. of  $\text{NaH}_2\text{PO}_4$ ,  $\text{Na}_2\text{HPO}_4$  and  $\text{Na}_3\text{PO}_4$  injected subcutaneously each caused a considerable increase in urinary phosphates, 70 to 100% of the injected P having frequently appeared in the urine. After successive subcutaneous injections of phosphate, less of the injected P is excreted in the urine than after the initial injection. The character of the diet and the nature of the phosphate injected had no apparent influence on the % of injected P excreted by the kidneys. It is impossible, however, to draw general conclusions with regard to these factors on the basis of these expts., due to variations in urinary P excretion in individual rabbits and to the effect of repeated injections of phosphate solns. on the urinary elimination of phosphates subsequently injected. Large increases in the phosphate content of the urine were noted accompanied by only slight increases in H ion concn." A. P. LOTHROP.

Vitamine studies. II. Does water-soluble vitamine function as a catalase activator? R. ADAMS DUTCHER AND FERDINAND A. COLLATZ. Minn. Agr. Expt. Sta. *J. Biol. Chem.* 36, 547-50(1918); cf. *C. A.* 12, 2613.—D. has recently shown (*C. A.* 12, 2613) that an apparent relationship exists between oxidative processes and vitamine storage in avian polyneuritis inasmuch as the tissues of polyneuritic pigeons are low in catalase content and feeding  $\text{H}_2\text{O}$ -sol. vitamine brings about normal catalase content accompanied by improvement in the condition of the birds. Expts. have been made to det. whether vitamine exts. possess the property of directly activating catalase or of bringing about a greater production of the enzyme. "The results indicate that  $\text{H}_2\text{O}$ -sol. B does not act as a direct activator of catalase, but instead probably (on account of its physiological properties) stimulates the organism to greater production of catalase." III. Observations on the curative properties of honey, nectar, and corn pollen in avian polyneuritis. *Ibid* 551-5.—The expts. were undertaken to prove or disprove the presence of vitamins in honey on account of statements in the affirmative which have been made in popular articles and because the consumption of larger amts. of sirups and honey has been encouraged in order to conserve the supplies of cane and beet sugar. As honey is high in  $\text{H}_2\text{O}$ -sol. substances and low in fatty materials, a search was made for the  $\text{H}_2\text{O}$ -sol. vitamine rather than its fat-sol. prototype. "Honey contains a small amt. of  $\text{H}_2\text{O}$ -sol. vitamine but the amt. is negligible. It is probable that the slight antineuritic properties of honey are overbalanced by the large amt. of carbohydrate present, for the presence of vitamins was made evident only by adsorbing the vitamins upon siliceous earth (Lloyd's reagent). There was very little evidence of the presence of  $\text{H}_2\text{O}$ -sol. vitamine in the dil. unevapd. nectar. Corn pollen is relatively rich in  $\text{H}_2\text{O}$ -sol. vitamine and it is possible that the small amt. of this in honey may have its origin in the pollen of flowering plants, either in the form of pollen grains adventitiously present, or in the digested products, which might be introduced by the salivary juices of the bee." A. P. LOTHROP.

**The effect of the material ingestion of desiccated placenta upon the rate of growth of breast-fed infants.** FREDERICK S. HAMMETT. Harvard Univ. *J. Biol. Chem.* 36, 569-73(1918); cf. *C. A.* 12, 167.—The expts. were designed to "det. definitely whether placenta tissue *per se*, when fed to nursing mothers, contains a substance or substances affecting the rate of growth of the breast-fed infants, it being a well-known fact that milk may contain as such, or slightly changed, various substances, ordinarily foreign to its make-up, ingested by the mother." All patients were given desiccated placenta prepared as previously described (*C. A.* 11, 2492) in doses of 10 grains in a capsule 3 times a day. Only those mothers were chosen for the study whose parturition was normal and only the wts. of those infants were recorded whose sole source of nourishment was mothers' milk. The subjects were also divided into 6 groups according to wt. at birth and their wts. were recorded on the 1st, 3rd, 5th, 7th, 9th, 11th and 13th days thereafter. The growth of 177 infants was studied. The rate of growth is increased by the ingestion of the dried placenta by the mother; the postnatal decline in wt. is less and the gain in wt. after the preliminary loss is greater in every case, the mean increase over the normal % change in wt. on the 13th day being over 60%. The growth cap. of the infants is also increased, "that is to say, the maternal ingestion of dried placenta tissue so stimulates the tissues of the infants feeding upon the milk produced during this time, that unit wt. is able to add on greater increments of matter, from day to day, than can unit wt. of infants feeding on milk from mothers not ingesting this substance." There is no hypertrophy of the mammary gland or an increased milk production as a result of placenta ingestion. "There must be contained in the desiccated placenta some substance, or substances, capable of passing through the maternal organism with at least a part of its activity retained. Being secreted by the mammary glands, it is passed on to the infant in the milk, there acting as stimulus to growth. It is not illogical to suppose that these substances in the placenta *in utero* may play an important part in the growth of embryo and fetus."

A. P. LOTHROP.

**The influence of the ingestion of the amino acids, adequate and inadequate proteins upon the production of catalase.** W. E. BURGE. *Am. J. Physiol.* 47, 351-5 (1918).—The amino acids, glycine and alanine, when introduced into the intestine, cause an increase in blood catalase; glutamic and aspartic acids do not cause such an increase. These observations are in harmony with the fact that the first two amino acids increase oxidation in the body, while the last two do not. The ingestion of the digest of an adequate protein, casein, as well as of an inadequate one, gelatin, is followed by an increased catalase content of the blood.

J. F. LYMAN.

**Food value of bran for carnivora.** L. LAPICQUE AND J. CHAUSSIN. *Compt. rend. soc. biol.* 81, 319-23(1918); cf. *C. A.* 12, 1478.—In the 1st series of expts. a com. flour of 85% extn. was thrown on a No. 50 sieve. The approx. 20% of the flour which was retained was reduced between smooth rolls and again thrown on the sieve. The portion which was then retained was termed "bran" and used in the expts. Two dogs ((1) and (2) weighing 7.6 and 5.9 kg., resp.) received daily 10 g. casein and 10 g. melted beef fat apiece and in addition 160 g. and 125 g., resp., of the unsieved flour which was found to maintain them in practical equil. The flour was then sieved as already described and the 30 g. of bran which were recovered from the combined ration of 285 g. was given to dog (1) with 145 g. of sieved flour, while (2) received only 110 g. sieved flour; the wt. of (1) was approx. const., while that of (2) decreased. The corresponding proportion of bran was then returned to each dog's ration; (1) lost wt. and (2) remained practically const. in wt. For the 2nd series of expts. a white flour was prep'd. by simply grinding some Australian wheat and accepting what passed through a No. 100 sieve; the bran employed was the 1st bran from Manitoba wheat

after the latter had been subjected to 82.5% extn. In addition to the usual amts. of casein and beef fat dogs (1) and (2) received daily 133 g. and 111 g., resp., of white flour and 36 g. and 26 g., resp., of bran; both dogs remained practically in equil. The bran was then withdrawn from (1) and a double amt. (52 g.) was given to (2), the remainder of the ration being maintained unchanged; (1) lost and (2) gained wt. The original amts. (36 g. and 26 g.) of bran were then fed as usual; (1) gained and (2) lost wt. Dog (1) was then given a double ration (72 g.) of bran and the bran was withheld from (2); (1) gained and (2) lost wt. The expts. were continued for a sufficient length of time and the increase and decrease in wt. of the dogs were sufficiently pronounced (as much as 350 g. in 14 days) to warrant the conclusion that those portions of wheat which are excluded from a 80% flour but are included in a 90% flour have distinct food value for carnivorous animals such as dogs. The latter, while not so well adapted as man to digest plant food, have been habituated for generations to digest bread and constitute good subjects for such experimentation.

H. S. P.

**Requisite minimum of sugar and usually unsuspected sources of carbohydrates.** HENRI BIERRY AND PAUL PORTIER. *Compt. rend. soc. biol.* 81, 574-6(1918).—Full grown rats which received a ration of coagulated egg white, bacon (or bacon fat), H<sub>2</sub>O and salts maintained their wt. and showed practically no disturbance of nutrition provided the total amt. of food was sufficient and egg white and bacon were fed in proper proportion; acidosis ensued when the ratio between fat and albumin exceeded a certain value. This practical maintenance of equil. in the apparent absence of carbohydrates is attributed to: (1) the presence in egg albumin of carbohydrates or carbohydrate-producing substances such as free sugar, glucosamine, etc. (amounting in all to 0.8-1.0% on the basis of fresh egg albumin); (2) the role played by the glycerol content of the fat (transformation of glycerol into dihydroxyacetone with further ready transformation of the latter into a hexose by polymerization). The result represented by (2) above is in harmony with the amelioration of acetonemia after ingestion of glycerol. The wt. of available sugar in the ration used is estimated at about 1/6 of that of the neutral anhydrous fat present. The influence of the protein material present as a source of carbohydrates is in harmony with observations on the decrease in acetonuria after ingestion of meat. There is considerable variation, however, between various proteins and fats as sources of carbohydrates. Certain amino acids are generators of butyric acid and Me<sub>3</sub>CO, while other amino acids do not possess this property. Certain fatty acids are very ketogenic, others are indifferent, while still others are antiketogenic. There exists a requisite min. of sugar as well as a min. of protein and this min. of sugar varies with the nature of the proteins, fats and sugars of the diet; disturbances of metabolism are only eliminated when there is a certain balance between these factors.

H. S. PAINE.

**Experiments on the nutritive value of standard brown-bread and white-bread.** C. EIJKMAN AND D. J. HULSHOFF POL. Utrecht Univ. *Proc. Acad. Sci. Amsterdam* 21, 48-52(1918).—The standard white bread made according to government prescription contained 60% inland wheat and (or) rye flour, 10% American flour and 30% potato meal. The brown bread contained 70% unbolted wheat and (or) rye flour, 25% potato meal and 5% grits and (or) pollard. The authors state that the protein, salts and vitamins of the potato meal are lost in the prepn. and that powdered dried potatoes are, therefore, better. Six fowls about 2 years old were used in the expts., 3 being fed on the white bread and 3 on the brown bread. The ration was about 100 g. and when the appetite failed, forced feeding was resorted to. The fowls living on white bread lost wt. immediately. After 11 weeks fowl 3 developed polyneuritis and died after a few days. Fowl 2 developed polyneuritis a week later but recovered when brown bread was fed. Fowl 1 lost wt. but was not ill and recovered

its wt. when white bread was fed. As fowls living on polished rice develop polyneuritis within 5 weeks the yeast in the bread is reported as probably retarding the appearance in the above cases. Of fowls 4, 5, 6, fed on the brown bread, 4 and 5 remained in good health until the conclusion of the expt. which lasted 20 weeks. Number 6 maintained its wt. for a fortnight and then lost wt. It showed signs of polyneuritis in the 17th week and died a few weeks later. The authors conclude that brown bread yields more satisfactory results than white bread, the results holding good for human beings. They recommend a finer grinding of the bran or the removal of the coarser outer layers and the restriction of the use of white bread as much as possible. F. P.

Relative digestibility of maize oil (corn oil), cottonseed oil and lard. E. W. ROCKWOOD AND P. B. SWICKES. *J. Am. Med. Assoc.* 71, 1649-50(1918).—Three adult dogs were fed on a ration of 40 g. cracker meal, 10 g. bone ash and 155 g. chopped lean beef, freed as much as possible from visible fat. In a fore period no fat was given and the ether-sol. material of the feces was considered the "normal" output. In the fat periods 40 g. of the fat tested were included in the daily ration. The feces were marked off by lampblack, dried after the addition of alc.-acid and the ether ext. detd. as usual. The mean percentages of fat metabolized were for corn oil 98.9, cottonseed oil 98.8, and for lard 97.8. Other expts. show that corn oil can well be substituted for other animal and vegetable oils in salads, and for shortening in cooking wheat foods. L. W. RIGGS.

Substitution of saccharin for sugar. W. E. BURGE. *Univ. Ill. Science* 48, 549-50(1918).—The three functions of sugar are as a sweetening agent, an energy producer, and as an agent to increase the oxidation in the body. The present study is concerned with detg. if the ingestion of saccharin will increase the oxidation in the body as measured by the catalase content of the blood. Expts. on dogs by ingesting 4 g. of sugar or 5 g. of sol. saccharin per kg. of body wt. showed that the saccharin produced a much more extensive increase in catalase than did the sugar. It is concluded that saccharin may be positively helpful in the diet particularly in a disease, such as diabetes, which is attended with defective oxidation. L. W. RIGGS.

#### ABNORMAL.

Studies of experimental scurvy. III. The influence of meat and various salts upon the development of scurvy. W. PITZ. *Univ. Wis. J. Biol. Chem.* 36, 439-66 (1918); cf. *C. A.* 11, 2488; 12, 2004.—"An improvement of the protein of the diet will protect guinea pigs from scurvy for a number of weeks and will greatly prolong the life of the animals, even though the physical character of the diet has not been improved. But while laxatives and lactose will prevent the development of scurvy in guinea pigs for 20 weeks, improvement in the protein of the diet, even when 10% of meat is added, will not protect them more than 13 weeks. When  $\text{Ca}_3(\text{PO}_4)_2$  was added with the meat the animals were protected for 18 weeks.  $\text{NaCl}$ , when added

to the milk, rolled oats, meat,  $\text{Ca}_3(\text{PO}_4)_2$  ration, also effected some further protection, demonstrating that low Cl is one among the many factors that may cause delay in the development of scurvy. This latter point is further emphasized by the remarkable protection afforded guinea pigs against scurvy by the ingestion of  $\text{CaCl}_2$  in the ration and shows that the Ca and Cl ions are of greater importance in the development of this disease than is P. The physical character of the diet and the character of the flora of the digestive tract are clearly of prime importance in the production of this disease, but other factors, such as those which make the diet more nearly chem. complete, which stimulate appetite and increase the flow of digestive juices and increase the resistance of the animals, which decrease the permeability of the intestinal wall, and which aid in correcting a deranged Cl metabolism, are of great importance and will protect the animals from scurvy for a considerable time. These expts. point to the little emphasized role of Ca salts in nutrition; namely, that of controlling the permeability of various animal tissues and thereby affording protection against invading agents. The sequence of events in the development of scurvy may be pictured thus: As feces accumulate in the cecum and large intestine of the animal and constipation has set in, peristalsis is decreased and the intestinal juices are secreted in less profusion, resulting in a lowering of the digestive power of the intestine and stomach and probably in the production of lesions in the intestines. Then, due to an increased permeability of the vessel walls, bacteria may invade the joints, toxic products are absorbed in greater amts. from the cecum and large intestine, and in some cases the whole protein mol. passes through the walls of the capillaries of the intestines into the blood stream. No claim is made that the retention of feces is the primary factor in the production of scurvy, but it is clearly a contributing and probably a very important factor in the development of the syndrome of this disease." A. P. LOTHROP.

**Appearance of an antiscorbutic substance during germination of cereals.** E. WEILL, G. MOURQUAND AND Mlle. PÉRONNET. *Compt. rend. soc. biol.* 81, 607-10 (1918).—Guinea pigs which received a daily ration of 50-60 g. germinated barley (equiv., after 3 days germination, to 30-40 g. dry barley) were compared with guinea pigs which were fed 25, 30-40 and 50 g. whole, dry barley and oats per day. The latter survived an av. of 26 days; clinical examn. disclosed no scorbutic symptoms, while anatomical examn. showed in general only minimal osseous modifications. The former survived an av. of 54 and 68 days (2 expts.). Pronounced symptoms of scorbutus were observed both anatomically and clinically (2-16 days before death in case of the latter). Some of the animals which were fed germinated grain lived 4 times as long as those which were given a ration of dry grain. These results contradict the supposition of Furst that antiscorbutic substances effective in the nutrition of guinea pigs are produced in cereals (barley, oats) within a 3-day period of germination. The fact that scorbutic lesions were much more pronounced in the guinea pigs which were fed germinated grain than in those which were fed dry grain was probably due to the longer survival of the former. Antiscorbutic power is developed later during the period of germination and development of the seedling, as shown by the fact that guinea pigs which were fed a mixt. of 3 days and 10 days germinated barley were normal after 200 days duration of the expt. H. S. PAINE.

**Trench sickness is due to avitaminosis.** L. BRUNTZ AND L. SPILLMANN. *Compt. rend. soc. biol.* 81, 1243-5 (1918).—Comparison of the symptoms in cases of trench sickness with those presented by animals receiving a vitamine-free ration indicates that this malady is due to lack of vitamins in the diet. H. S. PAINE.

**Diet with cirrhosis of the liver.** R. M. TEROL. *Revista Ibero-Americana de ciencias medicas, Madrid* 40, 29 (1918); *J. Am. Med. Assoc.* 71, 1447.—A milk diet is recommended as this leaves the liver in comparative repose while promoting diuresis.

An adult should take 3 liters of sterilized milk during the day by sipping a small amt. every one or two hrs. The small amts. are prescribed to avoid distending the stomach, causing retention and fermentation with results injurious to liver cells. The milk diet should be followed for a month when the ordinary diet may be slowly resumed with four small meals per day. In cirrhosis with hypertrophy the diet should be restricted to starchy foods and dry vegetables with little sugar or substances liable to putrefy. The aim is to reduce the production of toxins. In cirrhosis with atrophy, meat should be prohibited to ward off the production of toxins and salt should be restricted to 6 g. per day to guard against ascites and edema.

L. W. RIGGS.

## F. PHYSIOLOGY.

ANDREW HUNTER.

The presence of albumin in the urine of cadavers and its differentiation from pathological albumin. ERMINIO ALBERTARIO. Univ. Padua. *Arch. farm. sper.* 25, 330-6(1918).—Urine obtained from cadavers invariably contains albumin, the amt. depending upon the extent of putrefaction. The albumin comes from the walls of the bladder. It is not analogous to the so-called pseudoalbumin, since it gives a negative test for the latter, but it reacts positive with the sp. tests for pathological albumin.

A. W. DOX.

The rest nitrogen of the organs and tissues of normal and nephrectomized dogs. E. BECHER. Giessen. *Deut. Arch. klin. Med.* 128, 1-12(1918).—Besides in the blood there is also an increase in the amt. of rest N in the tissues of the most important organs after nephrectomy. It is most marked in the blood; then follow the spleen, liver, muscles, and other tissues. Under normal conditions the tissues do not contain more non-coagulable N than the blood. Calcd. by wt. most of the rest N is deposited in the muscles; then in order come the blood, liver, intestines, heart, etc. The total increased amt. of rest N deposited in all the tissues is more than the amt. of N excreted by a fasting nephrectomized dog of the same wt.

JULIAN H. LEWIS.

The metabolic gradient underlying colonic peristalsis. W. C. ALVAREZ AND ESTHER STARKWEATHER. *Am. J. Physiol.* 47, 293-301(1918); cf. *C. A.* 12, 1661.—In the colon, as in the stomach and small intestine, there are a graded catalase content and CO<sub>2</sub> production which are believed to underlie and give rise to gradients of rhythmicity, irritability and latent period which, in turn, det. the direction of peristalsis. The catalase content of colonic muscle is considerably lower than that of the more active small intestine. The gradient for the dog, cat, rat, rabbit and guinea pig was detd. There are marked differences in the gradients for the different species.

J. F. L.

Two new factors in blood coagulation—heparin and proantithrombin. W. H. HOWELL AND EMMETT HOLT. *Am. J. Physiol.* 47, 328-41(1918).—To the factors formerly recognized as concerned in blood coagulation, *vis.*, fibrinogen, thrombin, Ca, antithrombin and cephalin, there must now be added 2 others, heparin and proantithrombin. Heparin is a phosphatide having a ratio of N to P = 2.5 to 1. It is prepd. best from dog livers. It is very difficult to sep. from cephalin on account of their similar solns. Presumably it exists normally in blood, though that has not been demonstrated. Proantithrombin exists normally in blood. It is acted upon by heparin and converted, evidently by a reaction not enzymic, into antithrombin; its chem. nature is unknown. Heparin is not destroyed at 100°. Proantithrombin is rapidly destroyed in blood plasma at 70°. It may be pptd. uninjured from blood plasma by acetic acid or by (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> added to 1/2 satn.

J. F. LYMAN.

The influence of secretin on the number of red and white corpuscles and the erments and sugar content of the blood. B. FUJIMOTO. *Am. J. Physiol.* 47, 342-50 (1918).—Secretin injected subcutaneously into rabbits produces an increase in the

number of red and of white corpuscles, an increase in catalase, but no change in the diastase, glycolytic enzyme or sugar of the blood. J. F. LYMAN.

The viscosity of urine. R. BURTON-OPITZ AND ROBERT DINEGAR. *Am. J. Physiol.* 47, 220-30(1918).—An app. for detg. viscosity is described. Viscosity of pathol. urines varies much more widely than does sp. gr.; the latter is a less certain means of detg. the character of urine than the former. Normal adult urine is 1.2 times as viscous as  $H_2O$ , normal child's urine (4 to 5 yrs.) 1.1 times. Values for viscosity in some pathol. states are given. J. F. LYMAN.

Regeneration of blood serum proteins. I. Influence of fasting upon the curve of protein regeneration following plasma depletion. W. J. KERR, S. H. HURWITZ AND G. H. WHIPPLE. *Am. J. Physiol.* 47, 356-69(1918).—Plasma protein in dogs was reduced to about 50% its normal level by bleeding, and introducing into a vein washed dog corpuscles suspended in saline. Blood proteins were detd. by the refractometric method of Robertson (*C. A.* 9, 2913). In the fasting dog regeneration of serum albumin and serum globulin is a slow process, requiring 7 to 14 days. There is a tendency for globulin to be regenerated faster than albumin. There is no evidence from these expts. that serum proteins are concerned in any way as intermediary products between food protein and body tissue or parenchyma protein. Urinary N shows a primary rise for a few days following the loss of serum proteins from the body. II. Influence of diet upon the curve of protein regeneration following plasma depletion. *Ibid* 370-8.—Regeneration of serum proteins is more rapid and complete on a meat or mixed diet than during fasting. In the meat-fed dog complete regeneration may be effected in from 5 to 7 days. Regeneration is slower on a diet of bread and milk than on a diet of meat. The body appears to have about the same difficulty in regenerating its serum proteins as it does in the construction of cell protein. III. Liver injury alone; liver injury and plasma depletion; the Eck fistula combined with plasma depletion. *Ibid* 379-92.—After liver injury by  $CHCl_3$  or by P and also after the Eck fistula operation there is a marked delay in the regeneration of serum proteins. It is believed that the liver is concerned in maintaining the normal level of the blood serum proteins, a level that is remarkably const. in widely varying conditions of health and disease. J. F. LYMAN.

## G. PATHOLOGY.

H. GIDEON WELLS AND ANDREW HUNTER.

Action of adrenaline on the distribution of blood in man. GEORG ROSENOW. *Königsberg. Deut. Arch. klin. Med.* 127, 136-51(1918).—The intramuscular injection of adrenaline in man produces a short-lived decrease in the vol. of the forearm followed by a longer lasting increase. The increase in vol. is not due to the hindrance of the venous outflow, but to the fact that adrenaline has a stronger action on the vessels of the splanchnic area than on the periphery. The same effects of adrenaline are found in man as are found in exptl. animals. In toxic vasomotor injuries, especially of the splanchnics, adrenaline is the therapeutic agent of choice. On account of the rapidity with which the action passes off, the injections must be repeated frequently.

JULIAN H. LEWIS.

The hemolysin of paroxysmal hemoglobinuria. A. LORANT. Pozsony. *Deut. Arch. klin. Med.* 126, 148-56(1918).—The hemolysin at 0° in the serum of patients with paroxysmal hemoglobinuria is not sp. for either normal red cells or those of the patient. Therefore, it follows that the red cells of healthy people and of the patients are identical and have the same immunological properties.

JULIAN H. LEWIS.

Isolysins and autolysins in hemolytic icterus. KURT BECKMANN. *Deut. Arch. klin. Med.* 126, 305-17(1918).—In a case of acquired hemolytic icterus an isolysin and autolysin were found in the blood serum. In a case of the hereditary form of the

disease only an autolysin was found, and no isolysin. In the acquired form the hemolysin has its origin in the spleen which has an increase in its ability to destroy red cells. In the hereditary type the hemolysin is probably only secondary to an injured spleen, or is the same substance as in the acquired type but with a lower activity, and is capable only of hemolyzing previously injured cells.

JULIAN H. LEWIS.

**The blood serum in carcinoma.** CHARLOTTE LOEBNER, NÉE WRESCHNER. Tübingen. *Deut. Arch. klin. Med.* 127, 397-417(1918).—The serum of 43 patients with carcinoma was studied. The lowest protein value was 4.2%, the highest 9% with an av. of 7.3% (normal 8.2%). There seems to be a tendency toward an increase in the amt. of globulin in proportion to the albumin. The hemoglobin content of the serum rises and falls with the protein content. Of the 43 sera, 21 had a normal color, 10 were lighter, and 12 darker than normal.

JULIAN H. LEWIS.

**Tuberculin and tuberculosis.** V. REICHMANN. Jena. *Deut. Arch. klin. Med.* 126, 413-46(1918).—When tuberculin is injected into man there is a decrease in the number of lymphocytes and at the same time an increase in the number of the other leucocytes. There is no difference in the blood picture of a tuberculous individual and one injected with tuberculin. Fever alone is not a sign of a positive tuberculin reaction but is when accompanied by a decrease in the number of lymphocytes.

J. H. LEWIS.

**The cholesterol content of the blood in different forms of Bright's disease.** WILHELM STEPP. Giesens. *Deut. Arch. klin. Med.* 127, 439-67(1918).—Whenever there is a severe injury of the parenchyma of the kidney there is generally an increase in the cholesterol content of the blood. This holds true for acute as well as for glomerulonephritis. The longer a case of chronic nephritis exists, the more pronounced the interstitial changes, and the more marked the retention, the more seldom is the blood cholesterol increased. In nephritis the cholesterol value of the blood may be over 1%. The increased blood cholesterol may come from the fatty kidney or from an inability of the liver to regulate the cholesterol blood content. In a case of double nephrectomy in a dog the cholesterol content of the serum was doubled.

JULIAN H. LEWIS.

**Chemical changes in tuberculous tissues.** GEORGE T. CALDWELL. Univ. Chicago. *J. Infect. Dis.* 24, 81-113(1919).—The H<sub>2</sub>O content of normal bovine lymph glands constitutes about 81-82% of the moist wt. No very distinct differences are noted between peribronchial glands and those from the mesenteric region. The tubercle walls and the caseous material from lymph gland tubercles contain a lower % of H<sub>2</sub>O than does the normal tissue. In normal bovine liver tissue, the % of H<sub>2</sub>O is less than that of the tubercle walls or of the caseous material from liver tubercles. The specimens of caseous material from lymph gland and liver tubercles approach each other closely in their H<sub>2</sub>O content, the av. being about 75% for the bovine material. The alc.-ether-sol. substances from normal bovine lymph glands form about 24.4% of the dry wt., or about 4.4% of the moist wt. The walls of the lymph gland tubercles contain a distinctly larger amt. of lipins than does the caseous material or the normal tissue. On the contrary, the walls of the liver tubercles are poor in lipins as compared with the normal tissues, and they contain a smaller amt. of fats than does the caseous material from these tubercles. When calcd. on the basis of dry wt., the caseous material from lymph gland tubercles contains a smaller % of lipins than does the normal lymph gland tissue. When the ash is deducted, this difference disappears and the content of lipins becomes equal to or slightly greater than that of the normal tissue, but less than that of the tubercle wall. When calcd. on an ash-free basis, the lipin content of the caseous material from liver tubercles is distinctly less than that of the normal tissue but greater than the lipin content of the tubercle walls. Cholesterol forms about 6.5% of the lipins from the normal bovine lymph glands or about 1.5% of the dry wt. The lipins from the walls of lymph gland and liver tubercles contain, in every case,

2.3 times as much cholesterol as do the lipins from the normal tissues. This is an actual increase also when calcd. on the basis of the dry wt. The caseous material contains even a larger % of cholesterol than do the tubercle walls. Lecithin constitutes about 32% of the lipin fraction of normal lymph glands, or about 7.9% of the dry wt.; the corresponding values for normal liver are 41.2% of the fats, or 14% of the dry wt. The lecithin content of the fats from the tubercle walls is slightly less than that of the normal tissues, while there is a very marked reduction in the lecithin content of the lipins from caseous material of bovine origin. In caseous material from human lymph glands, lecithin formed 30.9% of the total lipins. The I nos. of the fats of the tuberculous lymph glands are higher than those of fats from the normal tissues. This observation does not hold true for liver specimens. In the latter, there is no difference between the I nos. of the lipins from normal and tuberculous specimens, although the values are practically the same as those from the fats from the lymph gland tubercles. In the residues of caseous material left after extn. with alc. and  $\text{Et}_2\text{O}$  the N content remains relatively high; in fact, the reduction in N content is only slight when the calcns. are made on ash-free residues. The % of N does not differ much from that of the normal proteins of these tissues. In caseous material in which there is no macroscopic evidence of calcification other than the presence of sandlike particles, Ca sometimes forms as much as 15% of the residue left after extn. of the fats. In such residues, the P content may reach 9%. The amt. of purine N in the walls of lymph gland tubercles is only slightly more than half that of normal lymph gland tissue, and the amt. is apparently much less in the caseous material. In the residues from the walls of liver tubercles, purine N is present in only slightly higher % than in the normal liver. The results here obtained would seem to indicate that the purines are even more abundant in the caseous residues of liver tubercles. The amt. of material which enters the  $\text{H}_2\text{O}$  soln. during extn. is distinctly less from caseous material than from the residues of normal tissues.

JULIAN H. LEWIS.

A study of the complements used in the Wassermann reaction. E. H. RUDIGER. Bismarck, N. D. *J. Infect. Dis.* 24, 120-32(1919).—The complements of fresh guinea-pig serum varied greatly in fixability, and therefore, a single complement serum is unreliable. A mixt. of 5 complement serums gave fairly uniform results. Human complement gave much weaker positive results than did guinea-pig complement. Guinea pig complement left on the clot and kept in the refrigerator remained fairly const. for 3 days, while complement which had been removed from the clots deteriorated more rapidly. Ramy's method of preserving complement by Na acetate was a total failure in the hands of the author. Glycerol seemed to prevent deterioration of complement for a few days. In complement preserved by glycerol fixability increased during the first 3 days and on the 7th day it still was nearly equal to the fresh serum.

JULIAN H. LEWIS.

The demonstration of immune opsonins for the pleomorphic streptococci in experimental poliomyelitis in monkeys. WILLA M. DAVIS. Mayo Foundation, Rochester, Minn. *J. Infect. Dis.* 24, 176-80(1918).—There occurs a well marked sp. increase in opsonins for the pleomorphic streptococcus in the serum of monkeys during attacks of poliomyelitis following the inoculation of virus. Since this increase in opsonins occurs toward strains derived from human cases as well as from exptl. poliomyelitis following the injection of virus, the pleomorphic streptococcus in this disease cannot be regarded as an accidental invader of the nervous system.

JULIAN H. LEWIS.

The nature of the proteins associated with antitoxin in antitoxic sera. ANNIE HOMER. *Proc. Physiol. Soc., J. Physiol.* 52, xxxiii(1918).—In both antitetanic and antidiphtheric sera the respective antitoxins are associated mainly with the pseudoglobulin fraction. The proportion associated with the euglobulin fraction is greater in the

former than in the latter serum. In antidyenteric serum the association of the antitoxins with the euglobulin fraction is still more marked, while in antimeningitic serum the main part is attached to the euglobulins. J. F. LYMAN.

**Antitoxic sera.** ANNIE HOMER. *Proc. Physiol. Soc., J. Physiol.* 52, xxxvii(1918); cf. *C. A.* 12, 2009.—Heat denaturation of serum proteins increases the proportion of pseudoglobulins pptd. by 28%  $(\text{NH}_4)_2\text{SO}_4$  and decreases its soly. in brine. While the activity of heat-denatured antitoxin is unimpaired, it is no longer in a condition suitable for use clinically. With serum in which approx. 30% of the protein had been denatured, the main bulk of the antitoxin was pptd. between 36 and 44%  $(\text{NH}_4)_2\text{SO}_4$  satn. Heating antitoxic sera at 56° for 15 hrs. or at 58° for 10 hrs. did not appreciably lessen the concn. of antitoxin. Heating at 65° for 30 min. caused the destruction of about 33% of the antitoxin. J. F. LYMAN.

**The influence of guanidine on the anaphylactic state.** DAVID BURNS. *Proc. Physiol. Soc., J. Physiol.* 52, xxxix(1918).—The properly regulated dose of a salt of guanidine, before or immediately after the administration of the toxic dose of serum to a sensitized animal, protects the animal in the majority of cases from anaphylactic shock. J. F. LYMAN.

ZINSSER, HANS: **Infection and Resistance. An Exposition of the Biological Phenomena Underlying the Occurrence of Infection and the Recovery of the Animal Body from Infectious Disease.** Chapter on Colloids and Colloidal Reactions by Stewart W. Young. 2nd Ed. New York: The Macmillan Co. 585 pp. \$4.25. For review see *J. Am. Med. Assoc.* 72, 596.

## H. PHARMACOLOGY.

ALFRED N. RICHARDS.

**Action of sucrose in urethritis.** RAFFAELE SALADINI. Univ. Rome. *Arch. farm. sper.* 25, 374-84(1918).—Cases of blennorrhagic urethritis are reported in which injections of sucrose into the urethra gave beneficial results and rapidly reduced the urethral secretion. A. W. DOX.

**Action of sugars on the bronchial secretion.** DOMENICO LO MONACO. Univ. Rome. *Arch. farm. sper.* 25, 1-11(1918).—Subcutaneous injections of sucrose diminish the bronchial secretion in advanced stages of tuberculosis. A diminution of coughing and night-sweats is observed simultaneously. A. W. DOX.

**The action of small doses of alcohol on the orientation power of the arm and hand.** G. GYLLENSWÄRD. *Skand. Arch. Physiol.* 35, 327-47(1918); *Physiol. Abstr.* 3, 423. —Five cc. of EtOH has, 50 minutes after administration, a marked influence on the orientation power of the arm and hand, as judged by the method of Blix. F. H.-F.

**The physiologic action of cantharis.** S. MORGULIS AND A. L. MUIHEAD. *Arch. Intern. Med.* 23, 190-6(1919).—Cantharis does not experimentally induce polycythemia, inasmuch as it does not cause a production of new cells, but merely occasions a condensation of the blood through the loss of water in the process of elimination of cantharis by the kidneys. F. HULTON-FRANKEL.

**The influence of alkali administration on the urinary excretion of lactic acid, and the possible significance of the latter in maintaining neutrality in the body.** J. J. R. MACLEOD AND H. J. KNAPP. *Am. J. Physiol.* 47, 189-207(1918).—Administration of alkali, by injection or by mouth, in amts. sufficient to disturb the acid-base equil. of the body increased the output of lactic acid in the urine in rabbits, dogs, cats and men. The increased lactic acid elimination was sufficient, however, to neutralize only a small part (at the most about 5%) of the alkali given. J. F. LYMAN.

**The effect of adrenaline upon the fatigue produced by the injection of the fatigue products, lactic acid and acid potassium phosphate.** C. M. GRUBER AND O. S.

KRETSCHMER. *Am. J. Physiol.* 47, 179-84(1918).—Fatigue induced in cat muscle by perfusing lactic acid or  $\text{KH}_2\text{PO}_4$  can be counteracted by adding adrenaline to the perfusing fluid, just as fatigue produced by exercise is counteracted by the same substance. In those cases in which adrenaline has no bettering effect vasoconstriction does not occur.

J. F. LYMAN.

The antagonistic action of epinephrine to the fatigue produced by the perfusion of acid sodium phosphate. C. M. GRUBER. *Am. J. Physiol.* 47, 185-8(1918).—Fatigue induced in cat muscle by perfusing  $\text{NaH}_2\text{PO}_4$  is counteracted by epinephrine (adrenaline). Marked recovery was accompanied by an almost complete cessation of the passage of the perfusion fluid through the muscle.

J. F. LYMAN.

The stimulation and paralysis of nerve cells and nerve endings. II. Paralysis by curari, strychnine and brucine and its antagonism by nicotine. J. N. LANGLEY. Cambridge. *J. Physiol.* 52, 247-66(1918).—The paralyzing effect of curari, strychnine and brucine is on the peripheral nerve cells, on which nicotine has a stimulating action. After large doses of drugs that paralyze peripheral nerve cells, blood pressure becomes low and cannot be permanently restored by any of the methods tried, *e. g.*, injections of gelatin, Ringer fluid, 0.04%  $\text{BaCl}_2$ , 6.0% gum with  $\text{Na}_2\text{CO}_3$  (Bayliss soln.), and pituitrin.

J. F. LYMAN.

The blood-pressure curve following an intraspinal injection of adrenaline. J. AUER AND S. J. MELTZER. *Am. J. Physiol.* 47, 286-92(1918).—Adrenaline introduced intraspinaly into monkeys caused a characteristic blood pressure curve different from that obtained after intravenous injections of the drug. There is a prolonged latent period and a comparatively slow rise in blood pressure, the max. being attained only after several min.; the pressure then continued plateau-like for a fairly long time. The descent to normal was comparatively very slow. As a rule, the pressure at the end of the pressor effect has not been observed to fall below normal.

J. F. LYMAN.

The effects of strychnine and caffeine upon the rate of learning. K. S. LASHLEY. *Psychobiology* 1, 141(1917).—Albino rats were trained in the circular maze after subcutaneous injection of strychnine sulfate and of caffeine. Others were trained after similar manipulations but without the drugs, as controls. Analysis of the data obtained gives the following results: Small doses of strychnine sulfate are without effect upon the rate of habit-formation. Large doses of strychnine sulfate, sufficient to produce tremor and incoördination of movement, accelerate learning. Caffeine, in doses of 0.5 mg. or more, retards learning in direct proportion to the size of the dose. Strychnine sulfate in large doses increases the accuracy of performance of a perfected habit. Large doses of caffeine result in increased activity and reduced accuracy of performance.

D. I. MACHT.

The action of some opium alkaloids on the psychological reaction time. D. I. MACHT AND S. ISAACS. *Psychobiology* 1, 19(1917).—The effect of morphine alone and in combination with other opium alkaloids depends upon the dose used and may be manifested by a change in the mean reading, a change in the mean variation of the readings, or by both of these; and in case of association tests, by the number of errors made in performing a mathematical calcn. After small doses of morphine, there is generally a primary stage of stimulation or quickened reaction time; this may or may not be followed by a secondary stage of depression, as indicated by narcosis and prolongation of the reaction time. After larger doses of morphine, the primary stimulation stage is very short and may be overlooked, whereas the secondary or stage of depression is predominant. From the expts. made with combinations of morphine with other opium alkaloids in the form of narcophine and pantopon, it appears that morphine given in such a form is more narcotic and correspondingly more depressant to the psychic

functions than when the same dose of morphine is administered to the same subject by itself. D. I. MACHT.

**Absolute disinfection of the hands in three minutes by means of a paste containing chloride of lime.** M. MONZIOLS. *Compt. rend. soc. biol.* 81, 600-2(1918).—M. has modified an American prep. consisting of equal parts of  $\text{Na}_2\text{CO}_3$  and chloride of lime. A mixt. of 10 g. pulverized  $\text{H}_3\text{BO}_3$  and 15 g. talc (in a packet) is made into a paste with sterile  $\text{H}_2\text{O}$  and 2 g. chloride of lime (in a closed tube) testing  $28-30^\circ$  on the English chlorometric scale. The paste is applied to the hands and sterilization is effected within 3 mins. The  $\text{Na}_2\text{CO}_3$  used in the original formula was found to be unnecessary. In view of the sensitiveness of the skin to alkalis,  $\text{H}_3\text{BO}_3$  was added in order to acidify the mixt. Amts. of the paste containing 0.25-2.0 g. chloride of lime may be used for sterilizing the operatory area in surgery. Remaining traces of Cl may be finally removed from sterilized areas by washing with a 10:100  $\text{NaHSO}_3$  soln.

H. S. PAINE.

**Iodine chloride.** E. FOURNEAU AND DONARD. *Compt. rend. soc. biol.* 81, 1192-6 (1918).—Since  $\text{ICl}_3$  is subject in aq. soln. to immediate and practically complete decompn. into  $\text{HIO}_3$ ,  $\text{ICl}$  and  $\text{HCl}$ , thus causing needless wastage of I and production of undesirable acidity, F. and D. recommend the abandonment of  $\text{ICl}_3$  as an antiseptic and the substitution of  $\text{ICl}$  therefor. They advise the following method of prep.  $\text{ICl}$ . Dissolve 100 g. I and 50 g. KI in the least possible amt. of  $\text{H}_2\text{O}$ , mix the soln. with 640 cc. Javel soln. containing 77.7 parts active Cl per l. and gradually add 180 cc. of 29.57%  $\text{HCl}$ . This soln. contains 0.20 cc.  $\text{ICl}$  per cc. The reaction by which  $\text{ICl}$  in the presence of  $\text{H}_2\text{O}$  is decompd. into  $\text{HIO}_3$ , I and  $\text{HCl}$  is reversible and may be stabilized by addition of  $\text{HCl}$ .  $\text{NaCl}$  is preferable for this purpose, however, and the final soln. is prepd. by using 5 cc. of the original soln. to 1 l. of 10:1000  $\text{NaCl}$  soln. A certain proportion of the  $\text{ICl}$  is decompd. in spite of the presence of  $\text{NaCl}$ ; it is therefore better to use 7.5-10 cc. instead of 5 cc. of the original soln. Measurements of the rate of decompn. of  $\text{ICl}$  in a 10:1000  $\text{NaCl}$  soln. showed that the  $\text{ICl}$  content of the soln. decreased after 72 hrs. in the ratio 67:42.

H. S. PAINE.

**Antiseptic properties and method of using iodine monochloride.** W. MESTREZAT AND TH. CASALIS. *Compt. rend. soc. biol.* 81, 1196-9(1918).—In addition to pronounced antiseptic power  $\text{ICl}$  (cf. preceding abst.) has absolutely no caustic action on the epidermis. The soln. employed contained 1.50 g.  $\text{ICl}$  per l.

H. S. PAINE.

**Antiseptic dressing of wounds on the battlefield.** H. VINCENT. *Compt. rend. soc. biol.* 81, 1200-11(1918).—V. reports observations showing the antiseptic action of a mixt. of 1 part dry  $\text{Ca}(\text{ClO})_2$  and 9 parts powdered  $\text{H}_3\text{BO}_3$  (applied as soon as possible after infliction of the wound) in preventing infection of wounds during the interval preceding surgical intervention. P. Duval, commenting on the above, contends that the proof of this favorable antiseptic action is not yet sufficiently conclusive.

H. S. PAINE.

**Prophylactic dressing of wounds.** H. VINCENT. *Compt. rend. soc. biol.* 81, 1240-3(1918).—V. replies to Duval (cf. preceding abst.).

R. A. GORTNER.

Intracellular respiration. III. Relation of the state of nutrition of paramecium to the rate of intracellular oxidation. E. J. LUND. *Univ. Minn. Am. J. Physiol.* 47, 167-77(1918); cf. *C. A.* 12, 1568.—The rate of oxidation in *Paramecium caudatum* is increased two to threefold by the ingestion of food accompanied, in these expts., by growth, but not by cell division. The change in the speed of oxidation seems correlated in some way to growth and starvation processes in the cell. IV. The rates of carbon dioxide production by starved and fed paramecia, and their possible relation to the rates of oxidation in the unfertilized and fertilized sea urchin egg. *Ibid.* 318-27(1918).—Fed paramecia produced CO<sub>2</sub> about three times as fast as did starving organisms. The magnitude of the increase in rate of oxidations after feeding a starved paramecium is similar to, although greater than, that found in animals such as the cat, dog or man after feeding protein. It is suggested that fertilization in the egg involves increase in permeability of the limiting plasma membranes around the yolk particles in the cytoplasm, which leads to digestion, absorption and synthesis of living protoplasm and hence increase in rate of oxidations just as occurs in paramecium.

J. F. LYMAN.

## 12. FOODS.

W. D. BIGELOW, F. F. FITZGERALD.

The determination of lactose. E. HILDT. *Compt. rend.* 167, 756-9(1918).—In detg. lactose in milk serum, practical difficulties arise from the partial hydrolysis of the lactose, especially in dichromated samples. Upon attempting to complete the hydrolysis, to det. the glucose and galactose produced and to calc. back to lactose, it is found that there is a partial destruction of the glucose and galactose if mineral acids are employed as hydrolyzing catalysts. Better results are obtained with the sulfonic acids, such as benzenesulfonic acid, phenolsulfonic acid, or related compds. These are used in the form of the Na or Ba salts, in presence of a corresponding amt. (titrated) of H<sub>2</sub>SO<sub>4</sub>. Excellent results are obtained for lactose in aq. solns., the accuracy obtained being about 0.5%. With 1% sulfonic acid, hydrolysis is complete in 3.5-4 hrs., at a temp. of 100°. The max. reducing power so obtained does not decrease if this heating is continued for an additional 4 hrs., indicating that there is no destruction of the glucose and galactose. Milk sera hydrolyze less readily than solns. of pure lactose. Comparing results obtained from milk serum and those from dried fat-extd. solids there is a discrepancy noted if the solids are dried on the water bath at 100°. There is close agreement if the drying takes place *in vacuo*. The relation of these observations to the possible reaction between carbohydrate, polypeptides and melanoid N is not clearly explained. When exts. are dried *in vacuo*, then heated at 100°, the loss in wt. is considerable, but the amt. of CO<sub>2</sub> evolved is small.

H. M. LANCASTER.

**Conclusions relative to the milk question; sessions of the food commission of the (French) biological society.** CHARLES RICHET. *Compt. rend. soc. biol.* 81, 841-7 (1918).—The commission's conclusions were in part as follows: Industrial use of casein should be limited to the amt. absolutely required by industries essential to the national defense. Milk should be consumed with as little modification as possible. Mfr. of cheese should be permissible only when it does not involve a decrease in the milk supply of the larger cities. Milk should be concd. without removal of fat in cases where transportation facilities for immediate consumption are not adequate. Skimmed milk should not be used for feeding animals, since only a small proportion of the milk protein is rendered available for human food in the form of meat protein. The commission publishes analyses (from the Paris municipal lab.) of 48 concd. milks of various types; a no. of instances of adulteration were noted. H. S. PAINE.

**The influence of personal error, shaking and time of heating on the determination of the specific gravity and refractive index of acetic acid serum.** J. C. VAN DER HARST AND C. H. KOERS. *Middelburg. Chem. Weekblad* 15, 1517-8; *Pharm. Weekblad* 55, 1565-7 (1918).—A reply to Schoorl (*C. A.* 13, 146), citing data to show that variations in the properties of milk serum as previously reported (*C. A.* 12, 2388) were not due to personal error. A reply from Schoorl is appended, maintaining that personal error was at least a large factor. JULIAN F. SMITH.

**Determination of non-digestible residue "in vitro" by the action of pancreatin on grains or their milling products and bread.** L. DEVILLERS. *J. pharm. chim.* 18, 5-12 (1918); cf. *C. A.* 12, 2001.—In the previous method, starch is not completely dissolved, due to the enveloping gluten. To dissolve gluten previously, cover 5 g. of the cleaned whole grains with 0.2 *N*  $\text{Na}_2\text{B}_4\text{O}_7$  + 3 vols. of  $\text{H}_2\text{O}$ , add 1 cc. of 1% pancreatin soln. in  $\text{CHCl}_3$ - $\text{H}_2\text{O}$  and expose to 55° in a glass-stoppered vessel for at least 10-12 hrs. This diminishes the stickiness of the gluten. Then shake well, strain and wash with warm  $\text{H}_2\text{O}$ , return the grains to the flask, add 25 cc. 0.2 *N*  $\text{Na}_2\text{B}_4\text{O}_7$ , 3 cc. *N*  $\text{CaCl}_2$  and 2.5 cc. of pancreatin soln., fill up to 100 cc. with  $\text{H}_2\text{O}$  and digest for 2 hrs. at 55°, stirring continuously. The gluten is now dissolved. To digest the pptd. starch, proceed as in the previous method. In the case of flour, mix 5 g. thereof with 2.5 cc. of pancreatic soln. and a few drops of  $\text{H}_2\text{O}$  and heat the paste in a capsule to 55° for 30 min. The liquefied mass is then mixed with solns. of borax and pancreatin and  $\text{H}_2\text{O}$  to make 100 cc., then treated further in the same manner as the grain. In the case of bran, only 2.5 g. are taken, and of pancreatic soln. sufficiently more to moisten it. In the case of bread, the presence of gluten (although modified in baking), requires 12 to 18 hrs. heating during the 2nd digestion. Continuous stirring is here very essential. S. WALDBOTT.

**Determination of total nitrogen in two samples of bran.** BOULUD. *Compt. rend. soc. biol.* 81, 912-3 (1918).—B. reports typical total N content of bran. One sample (from Manitoba wheat ground by millstones) in the form of small glistening, clear yellow, almost transparent lamellae contained 2.11% total N; the other sample (prepd. by Pointe's method) consisted of large opaque lamellae preserving the form of the envelope of the grain and contained 1.93% of N. H. S. PAINE.

**The chemical constituents in *Cycas revolute* Thunb.** I. K. YOSHIMURA AND N. SAGAVA. *Tokyo Kwagaku Kwaishi (J. Tokyo Chem. Soc.)* 39, 1116-21 (1918).—The starch obtained from the seed and stem of the plant is used for food in the southern part of Japan. Food poisoning sometimes accompanies the use of the improperly purified product. The present study was undertaken for the isolation of a poisonous principle. The stem used for the study was obtained from the plant grown in Kagostima, Japan. It contains 21.05% air-dry matter. This air-dry matter contains 9.15% crude protein (1.45% total N, 1.21% protein N, 0.24% non-protein N), 0.56%

crude fat, 6.04% crude fiber, 3.05% ash, 81.20% sol. non-nitrogenous matter and 44.50% starch. From the hot aq. ext. of the stem, *arginine* was isolated. S. KOMATSU.

Relative digestibility of maize oil, cottonseed oil and lard (ROCKWOOD AND SWICKES) 11E. Net energy values of alfalfa hay and of starch (ARMSBY, FRIES) 11E. The action of organic acids on metals (FOUW) 9. Nutritive value of standard brown-bread and white-bread (EIJKMAN, POL) 11E.

**Drying gluten.** G. A. OLSEN. U. S. 1,289,883, Dec. 31. Gluten is rolled into a solid mass under  $H_2O$  and this mass is then placed in an oven maintained at a temp. just slightly under  $100^\circ$  and during the slow drying of the gluten the pressure in the oven is reduced to cause the mass fully to expand and after thorough drying the pressure is gradually increased to atm. pressure, to equalize the pressure on the dried material. The pat. is "dedicated to the public" for free use.

**Preserving albumin.** M. D. M. VAN DER HAGEN and B. A. C. DAAMEN. Brit. 121,451, Mar. 15, 1918. In a process of preserving albumin by evapg. it to dryness, the albumin is mixed with milk and the mixt. evapd. at a temp. of  $100^\circ$  at atm. pressure, or a lower temp. and a reduced pressure may be employed. The process is stated to be particularly applicable to albumins derived from molluscs.

## 14. WATER, SEWAGE AND SANITATION.

EDWARD BARTOW AND W. F. MONFORT.

**Determination of the amount of chlorine required for purification of water; chlorine index.** S. COSTA AND H. PECKER. *Compt. rend. soc. biol.* 81, 167-70(1918).—The amt. of Cl, in mgs. per l., consumed by  $H_2O$  under certain definite conditions is termed the Cl index and represents the wt. of Cl required to purify and sterilize the water. The following technic is employed. Two solns. are prepd., viz.: (1) a soln. containing 200 mg.  $NaClO$  per l., 5 cc. of which are equiv. to 1 mg. Cl; (2) a  $Na_2S_2O_8$  soln. prepd. by dilg. 28.1 cc. of a 0.1 N soln. to 1 l. so that 1 cc. corresponds to 0.1 mg. Cl. Five cc. of the  $NaClO$  soln. (the Cl content of which has been accurately detd.) are added to 200 cc. of the  $H_2O$  to be examd. and the mixt. is allowed to stand 30 mins.; the available Cl is then detd. by titration with the  $Na_2S_2O_8$  soln. after addition of 10 drops of a 20:100 KI soln., 10 drops glacial  $AcOH$  and several drops of dil. starch paste. Numerous expts. showed that sterilization of  $H_2O$  is as a rule only effected when the amt. of Cl employed attains the value of the Cl index as thus detd. The index indicates the max. amt. of Cl required and addition of amts. in excess of this is unnecessary. Examn. of more than 2000 samples of  $H_2O$  showed that the Cl index varied from 0.5 to 5 mg. per l. The value of this index constitutes an excellent criterion of the character of the  $H_2O$  under examn.

H. S. PAINE.

Improvement of a hydrogen sulfide water by aëration and lime treatment. C. G. GILLESPIE. *Bull. Calif. State Bd. Health*, 1918; *Eng. Contr.* 50, 467(1918).—Aëration of a well water containing 20 p.p.m.  $H_2S$  proved satisfactory, and the addition of lime reduced hardness. LANGDON PEARSE.

Control of algae in irrigation canals by copper sulfate. R. K. TIFFANY. *U. S. Reclamation Record Nov.* 1918; *Eng. Contr.* 50, 558(1918).—Friction losses were increased by algae, which treatment with  $CuSO_4$  removed. Details are given. LANGDON PEARSE.

Need of certain investigations for increasing the efficiency of water filter plant design and operation. J. W. ARMSTRONG. *Munic. County Eng.* 56, 5-6(1919).—Urges need of data in mixing, baffling and coagulation basin design. L. P.

Operating results of slow sand filtration plant at Providence, R. I. M. H. BRONSDON. *Ann. Report, City Engineer*, 1917, *Eng. Contr.* 50, 465(1919).—Each filter was scraped 17 times a year and gave 8063.9 total hours of service, the runs being from 6.38 to 73.17 days, averaging 19.75. Bacteria (24-hr. agar  $37.5^\circ$ ) after chlorination were 10 per cc. for average of year, after filtration 20, with raw water av. 1,680. L. P.

Fine screens and chlorine meet Daytona conditions. G. W. SIMONS, JR. *Eng. News-Record* 82, 99-101(1919).—Seven % removal is obtained with sewage containing 95.7 p.p.m. suspended matter by openings  $\frac{3}{16} \times 2$  in. in Rinsch-Wurl screen, 6 ft. diam. This compares with 58 to 72% removal in tanks elsewhere in Florida. Ten cu. ft. screenings are caught per million gals. sewage. Cl applied is 5 lb. per million gals., removing 80% all bacteria. LANGDON PEARSE.

Efficiency of lime for correcting acidity in sludge. C. E. ALBRIGHT. *Phila. Bureau Surveys*, 1917 *Report*; *Eng. Contr.* 50, 460(1918).—The use of 10 lbs. lime per day had a marked effect on Imhoff sludge. Analytical data are given. LANGDON PEARSE.

Consolidation of sludge as a dewatering method. A. S. MARTIN. *Surveyor*, Oct. 25, 1918; *Eng. Contr.* 50, 467(1918).—Consolidation of sludge by pressure is workable on septic or settling tanks. A deep shaft is suggested. LANGDON PEARSE.

Sludge disposal at Providence, R. I. M. H. BRONSDON. *Ann. Rept. City Engineer* 1917; *Eng. Contr.* 50, 473(1918).—The cost of sludge disposal was \$7.10 per ton of dry solids. Details of pressing are given. LANGDON PEARSE.

Cleaning septic tank at Camp Lee. *Munic. J.* 45, 507-8(1918).—The use of an auto-ejector (auto truck with tank and pumps) is described. LANGDON PEARSE.

The Croydon and Wolverhampton sewage experiments. EDWARD WILCOX. *Assoc. Managers Sewage Disposal Works* 1918; *Eng. Contr.* 50, 413(1918).—At Croydon artificial fertilizers are being used to restore the sewage farm. At Wolverhampton settling expts. have been made on Dortmund tank designs to prevent eddies at entrance. LANGDON PEARSE.

Sewage disposal of London by sludge ships. G. W. HUMPHREYS. *Proc. Inst. Civil Engrs.* 204; *Eng. Contr.* 50, 429(1918).—Sludge ships, carrying 1000 tons each, take sludge from chem. pptn. works about 52.5 nautical miles to dump in sea, at a cost of 8.8 cents per ton including capital charges. Cost of treatment has averaged \$5.66 per mill. gals. Capital charges are included. In grains per gal., 4 of  $CaO$  and 1 of  $FeSO_4$  are used. LANGDON PEARSE.

Waste products of cities and the war. W. T. KNOWLTON. *League Calif. Municipalities* 1918; *Munic. J.* 45, 510-3(1918).—The wastes discussed are ashes, rubbish, sewage, street sweepings, trade wastes, dead animals and garbage. Details of disposal are given. LANGDON PEARSE.

Carbon tetrachloride vapor as a delousing agent. M. H. FOSTER. *Public Health Repts.* 1918, 1823-7. (Reprint No. 489.)

Water softening for textile purposes (KING, CHAMBERS) 25.

KINNICUTT, LEONARD P., WINSLOW, C. E. A. AND PRATT, R. WINTHROP: *Sewage Disposal*. 2nd Ed. Rewritten. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Ltd. 547 pp. \$4.

Apparatus for bacterial treatment and separation of solids from sewage. P. F. BROWN. U. S. 1,289,378, Dec. 31. The app. is of the Imhoff type.

## 15. SOILS, FERTILIZERS AND AGRICULTURAL POISONS.

J. J. SKINNER.

Organic phosphorus of soil: experimental work on methods for extraction and determination. C. J. SCHOLLENBERGER. Ohio Agr. Expt. Station. *Soil Science* 6, 365-95(1918).—A detailed description is given of a modification of the Potter and Benton method (*C. A.* 10, 2950) for detg. inorg. P, and of the Neumann method for detg. total P in the  $\text{NH}_3$  ext. of soils. An outline is also given of what were found to be the most favorable conditions for the preliminary removal of bases from the soil, and of the best conditions, with respect to strength of  $\text{NH}_3$  soln., time of digestion, etc., for the prepn. of ammoniacal exts. intended for the study of the soil content of organic P. It is shown that as solvents for the organic P of the soil studied, solns. of the hydroxides of the fixed alkalis are not superior to  $\text{NH}_3$ . One extn. by  $\text{NH}_3$  when carried out under the proper conditions was found to remove practically all the organic P from the soil that is capable of being taken into soln. by  $\text{NH}_3$ . No consistent relations were observed in these solns. between the content of  $\text{NH}_3$ -sol. org. matter (humus), humus ash,  $\text{SiO}_2$ ,  $\text{Fe}_2\text{O}_3$ , and  $\text{Al}_2\text{O}_3$ ; nor between the total org. matter and the organic P in  $\text{NH}_3$ -exts. prepd. in various ways, although there was a general tendency for these to vary together. The most satisfactory method for sepg. clay from ammoniacal soil exts., having in view the max. content of org. P, was found to consist in filtering the ext. through a layer of the soil itself supported by a flat paper filter on a Buchner funnel as described by McIntire and Hardy (*C. A.* 9, 346). Evidence is presented that inorg. P adsorbed by colloids, org. or inorg., is not included in the apparent content of org. P as detd. by the methods used. Detns. of humus, color and org. P in  $\text{NH}_3$ -exts. of 4 depths of the soil indicate that these  $\text{NH}_3$ -sol. constituents are present in about the same relative proportions in the 4 depths examd. The total N content of the same 4 depths of soil stand in ratios very similar to those exhibited by the  $\text{NH}_3$ -sol. constituents named.

W. H. ROSS.

Accurate determination of soil nitrates by the phenoldisulfonic acid method H. A. NOYES. *J. Ind. Eng. Chem.* 11, 213-8(1919).—The *modified* method is given in detail and those conditions under which, and directions as to how, details are to be varied are included. The more important points considered in working out the *modified* method were: variations between soils, the extn. of nitrates, the presence of chlorides, the filtration of soil and water mixts., the removal of interfering substances, quantity of soil to use, reagents and methods of using, the colorimeter and how to use it. Data are given for soils of widely different origin, compn. and reaction showing that nitrates are extd. from soils by distd. water, that the *modified* method overcomes inaccuracies caused by the presence of chlorides by keeping down temps. and prevent-

ing violent localized exothermic reactions and that freshly prepd.  $\text{Ca(OH)}_2$  removes interfering coloring matter and throws sol. iron out of soln. Special reasons are given for the selection of the Schreiner colorimeter (*J. Am. Chem. Soc.* 27, 1192(1905)). The colorimeter readings for the 74 soils and conditions investigated are given.

H. A. NOYES.

**Soluble salt content of soils and some factors affecting it.** M. M. MCCOOL AND C. E. MILLAR. East Lansing. Michigan Agr. Expt. Station, *Tech. Bull.* 43, pp. 1-47(1918).—By the freezing point method (*C. A.* 9, 3316) of measuring the concn. of the soil soln. it is shown that the translocation of salts in the soil is due mainly to water movements. When large quantities of salt are present there is a movement to areas of lower concn. even when water movements are prevented. Higher water contents of the soil aid this movement. Since the sol. salt content of field soils is relatively low, according to the data presented, it is thought probable that plants are supplied with food elements by diffusion from local areas around the roots only. The accumulation of sol. salts on the surface of uncropped areas indicates that when water movements occur in the soil, salts are carried along with it. That these movements do not take place to any great depth is evidenced by the results of various investigations showing but little movement of water from the subsoil to the feeding zone of the roots. It is considered improbable that any great quantity of sol. material is supplied to the plants from depths below those of root penetration. The quantity of sol. salts in greenhouse soils may become too great for proper plant development, and in certain muck soils plant growth may be inhibited by the accumulation of sol. substances in the upper layers. Expts. made with corn and barley cultures show that plants may materially reduce the sol. salt content of the soil. Field expts. also give evidence in the same direction, but to a less marked degree. As a result of lab. expts. it would appear further that the constituents of soils which have been cropped for a long period of years go into soln. at a somewhat slower rate than do those of the corresponding virgin soils. The rate of soln. in the case of the soils studied is governed to some extent by temp.; it is more rapid at  $25^\circ$  than at temps. approaching  $0^\circ$ . The moisture content, moreover, has a marked influence on the rate of soly. of the soil constituents, and it is pointed out that biological activities probably play an important role in these phenomena. A seasonal variation in the salt content of field soils was shown by an examn. of several soil classes at different periods during the spring and summer months. In the case of all the mineral soils tested, there was noted a tendency for the soil soln. to reach a max. concn. in the early summer when plant growth is at a max. The behavior of a muck soil used in the expts. was radically different especially during the latter part of the season when a decided tendency for the concn. of the soil soln. to increase still further was manifested. It is suggested that the seasonable variation in the sol. salt content of soils may play an important role in the results obtained from the use of fertilizers. The work is being continued. W. H. ROSS.

**Determining the absolute salt content of soils by means of the freezing-point method.** GEORGE J. BOUYOUCOS AND M. M. MCCOOL. Mich. Agr. Expt. Sta. *J. Agr. Research* 15, 331-6(1918); cf. *C. A.* 10, 1687, 2381; 12, 1094.—After they were washed several times with distd.  $\text{H}_2\text{O}$  the lowering in the f. p. of several soils was found to be almost uniform,  $0.0007^\circ$  for heavy sandy loam, loam, clay loam and clays; and  $0.005^\circ$  for sands and light sandy loams. This indicated that at a high moisture content or in excess of  $\text{H}_2\text{O}$  the f. p. method could be used to det. the abs. salt content of all normal soils with a high degree of accuracy. That air-drying does not introduce any error was shown by taking the f. p. of 15 samples of soil before and after air drying, all samples having first been washed until practically all the sol. salts were removed. Detns. of the f. p. were made with 14 samples of soil under varying conditions of season,

rainfall, culture, and at various depths, 15 g. of the soil being mixed with 10 cc. of  $H_2O$  (in the light soils the proportion being 20 g. to 10 cc. of  $H_2O$ ). The results show that the season of the year, the amt. of rainfall and the time elapsing after a rain, temp., rate of evapn., cultural conditions of the field, and depth of sampling all cause variations in the lowering of the f. p. from 0.010 to 0.200°. (Cf. C. A. 12, 732.)

R. N. HARGER.

**Soil factors affecting the toxicity of alkali.** F. S. HARRIS AND D. W. PITTMAN. Utah Agr. Expt. Sta. *J. Agr. Research* 15, 287-319(1918); cf. C. A. 10, 83.—Ten grains of wheat were planted in 200 g. of soil contg. amts. of NaCl ranging from 0 to 4000 p. p. m., or  $Na_2CO_3$  or  $Na_2SO_4$  in amts. ranging from 0-10000 p. p. m. The influence of the texture of the soil, amt. of org. matter and moisture content were studied. To show the effect of these various factors upon the toxicity of the salts data were obtained as to number of seeds germinating and total wt. of dry matter exclusive of roots at the end of 21 days. In all, 12000 such expts. were carried out. The results are shown graphically. The authors found that mere size of soil particles had no appreciable effect upon the toxicity of the salts but that loams were more tolerant of the salts than either sand or clay, the coarse loams being the most tolerant. Org. matter increased the resistance to alkali when the soil was sufficiently moist, but in a soil of limited moisture content it decreased the resistance. Increase of moisture up to the max. that will produce good crops increased the resistance to alkali. Up to 3000-4000 p. p. m. the three salts were beneficial,  $Na_2CO_3$  being most so in greater concns. The order of toxicity was:  $Na_2SO_4$ ,  $Na_2CO_3$ , NaCl, the last being most toxic. To ascertain the actual concn. of the solns. used, solns. of the salts were added to mixts. of varying proportions of sand and loam and the f. p. was detd. The f. p. was much lower where the % of loam was high, showing that the soil had absorbed some of the salt; where the % of sand was high the f. p. was generally higher, indicating that the soil had a greater affinity for  $H_2O$  than for the salt.

R. N. HARGER.

**Ash absorption by spinach from concentrated soil solutions.** RODNEY H. TRUE, OTIS F. BLACK AND JAMES W. KELLY. Bur. Plant Industry, U. S. Dept. Agr. *J. Agr. Research* 16, 15-25(1919); cf. C. A. 12, 2208; 13, 613.—Spinach plants were grown in soils which had been fertilized with manure, "acid complete," "basic complete," or very large treatments of acid phosphate,  $CaCO_3$ , KCl, NaCl,  $Na_2SO_4$ , or  $NaNO_3$ . Data are given showing the effect upon the growth of the plants, and the amt. and compn. of the ash, the ash from roots and tops being analyzed separately. The best results were secured with fertilizers having a basic nature. Acid phosphate and  $Na_2SO_4$  also gave good results, while the others produced poor growth, KCl giving the lowest yields. The total ash of the tops was highest with NaCl,  $CaCO_3$ , and acid phosphate and lowest with KCl and "basic complete," while in the roots the highest ash was with acid phosphate and manure and lowest with KCl and Na salts. The only ash constituents showing any great variations were  $SiO_2$ ,  $K_2O$  and  $Na_2O$ .  $CaCO_3$  and acid phosphate caused  $SiO_2$  to be very high in both tops and roots.  $K_2O$  was high in the presence of  $Na_2SO_4$  and manure and very low with NaCl and low with acid phosphate, while with KCl the  $K_2O$  content was medium. In the tops the  $Na_2O$  was very high with NaCl and high with  $Na_2SO_4$ . In the cases of  $SiO_2$  and  $K_2O$ ,  $Na_2O$  and  $CaO$ , and  $K_2O$  and  $MgO$  the high absorption of one constituent was accompanied by the low absorption of the other. The results suggest that Na may in some cases replace K in spinach fertilizer and since the Mg-Ca ratio is greater than unity the authors suggest the use of Mg salts in fertilizer for this crop.

R. N. HARGER.

**Champaign county soils.** C. G. HOPKINS, J. G. MOSIER, E. VAN ALSTINE AND F. W. GARRETT. Illinois Agr. Exp. Sta., *Soil Rpt.* No. 18, 61 pp.(1918).—The results

of chem. analysis and fertilizer expts. on the principal soil types of the county are given. The soils are mapped into 4 groups, the upland prairie soils comprizing over 90% of the area. The plant food elements of the different soils vary widely. The upland prairie soils are generally higher in these constituents. The org. matter of the upland prairie soils is also higher than that of the upland timber or terrace soils. More than 80% of the soils of the area contain no lime to a depth of 20 inches. P fertilizers gave increased crop yields, when applied with org. débris. J. J. SKINNER.

**Pecan rosette in relation to soil deficiencies.** S. M. McMURRAN. U. S. Dept. Agr. *Bull.* 756, pp. 11(1919).—Pecan rosette is almost unknown on the river flood plain soils of southern Louisiana; here the soil is deep and black, of high fertility and  $H_2O$ -holding capacity as compared with the typical sand and sandy clay of the Atlantic and Gulf Coastal plains, where the disease is so widely prevalent. The rosette of pecans appears to be associated with soil conditions; its occurrence is most prevalent in soils of low crop-producing power. Lime expts. show that liming the soil does not prevent the disease, nor is there any correlation between acid soils and rosetting. The incorporation of large amts. of stable manure in the soil improved the growth and partially prevented the outbreak of the disease. J. J. SKINNER.

**Some general information on lime and its uses and functions in soils.** M. M. MCCOOL AND C. E. MILLAR. Michigan Agr. Exp. Sta. *Special Bull.* 91, pp. 21 (1918).—The sources of lime in Michigan are limestone deposits, and marl beds. The changes which lime undergoes in the soil are discussed and general information is given. J. J. SKINNER.

**Soil investigation at Soerabaja.** P. A. A. F. EIJKEN. *Geneesk. Tijdschr. v. Ned.-Indië* 58, 113-39; *Chem. Weekblad* 15, 1519-20(1918).—Report of a bacteriol. and chem. investigation of the soil in the vicinity of Soerabaja, in connection with plans for a sewer system. The use of septic tanks with underground outlets is recommended on the basis of the findings. JULIAN F. SMITH.

**Effect of sulfonation and nitrification on rock phosphate.** J. W. AMES AND T. E. RICHMOND. Ohio Agr. Expt. Station. *Soil Science* 6, 351-64(1918); cf. C. A. 12, 1676.—A study was made of the action on rock phosphate of the acidity produced by the oxidation of S and of N compds. when incorporated separately or combined with the phosphate in different soils. In the sulfonation expts., 2 g. of S were added to 500 g. portions of the soil without and with varying amts. of  $CaCO_3$ , in order to study the effect of the processes in acid soils and in soils supplied with basic material. In an acid soil the oxidation of the S was found to proceed vigorously, approx. 50% being changed to the form of sulfate. The addition of  $CaCO_3$  to an acid soil depressed sulfonation somewhat, but in sand mixts. the presence of  $CaCO_3$  was found to be essential. In the absence of other bases the Ca of rock phosphate did not serve as a base for the sulfofying process to any appreciable extent. When phosphate rock was added to an acid silt loam at the rate of 1900 parts per million, the oxidation of S incorporated with the phosphate in the absence of  $CaCO_3$ , or N carriers, changed 630 parts of P into a form sol. in neutral ammonium citrate soln. In a basic soil, or when  $CaCO_3$  was added to the mixt., the acidity resulting from sulfonation was neutralized by the Ca present as carbonate, and the solvent action on the phosphate was therefore much less than occurred in the acid soil. When S and dried blood were added to an acid soil, the oxidation of the S proceeded actively but nitrification in the absence of  $CaCO_3$  was practically inhibited by the acidity resulting from the oxidation of the S. The transition from protein apparently ended with the formation of  $NH_3$ , which in turn reacted to neutralize the acidity arising from the sulfofying organisms. Less P was consequently changed to a sol. form when blood was added to rock phosphate and S in soil mixts. than when the S and phosphate were used alone. With  $(NH_4)_2SO_4$  there

was a still further decrease in the amt. of citrate-sol. P. Whatever action the  $(\text{NH}_4)_2\text{SO}_4$  has had is attributed to the sulfate ion rather than to biochem. action since nitrification of  $\text{NH}_3$  did not occur in a soil deficient in bases unless  $\text{CaCO}_3$  was added. Nitrification is stimulated by rock phosphate to a very limited extent. It is not an active agent for increasing the soly. of rock phosphate mixed with soil, and evidence is given to show that the Ca of the soil existing chiefly as silicates and partly in other combinations is almost, if not altogether, as readily attacked as rock phosphate.

W. H. Ross.

A preliminary study of the influence of chlorides on the growth of certain agricultural plants. W. E. TOTTINGHAM. *J. Am. Soc. Agron.* 11, 1-32(1919).—In a review of the previous field and greenhouse investigations on the effect of chlorides upon the growth and compn. of plants extremely variable results are shown to have been obtained. This is attributed to differences in the species of the plant, the type of soil, and especially to the complex factors considered as climate. In the present investigation the introduction of KCl and NaCl into water cultures was found to affect but slightly wheat plants during the first 5 weeks of their germination. Buckwheat grown to apparent maturity in similar cultures was decidedly affected by the application of these chlorides. Although seed production remained apparently undisturbed, the length of roots and the yield of dry matter was depressed. This effect was most pronounced in the presence of NaCl. Radish responded only slightly, in yield and compn., to the application of KCl and NaCl along with complete fertilizer in soil cultures in the greenhouse. Under similar conditions increased production of dry matter and of the percentages of sugars therein resulted with the carrot, while the reverse was true of the parsnip. In the latter case NaCl was particularly injurious. The sugar beet gave the same general responses to chlorides as did the carrot when grown in the greenhouse. While the roots were more watery where chlorides were applied, the yield of dry matter was greatly increased. The dry matter of such roots contained more glucose, but less sucrose, than that obtained from cultures in soil not receiving chlorides. Similar responses followed the application of common salt alone to beets grown in the field. The potato produced increased yields of dry matter in the tuber when KCl was supplied in place of  $\text{K}_2\text{SO}_4$  in a complete fertilizer ration to soil cultures in the greenhouse. Relative to the percentage of starch different varieties were found to respond differently. The results indicated that the variety of plant was more important than the type of soil in detg. this effect of chlorides. In field cultures in a dry season the application of KCl in a complete fertilizer decreased the yield of dry matter in the tubers, but in a season which was very humid towards its close no significant differences in compn. or cooking quality were found between tubers produced where  $\text{K}_2\text{SO}_4$  and KCl were employed separately in a complete fertilizer ration. NaCl applied alone altered the compn. of the tubers only slightly, but affected their quality seriously. The paper is followed by a full bibliography.

W. H. Ross.

New ways for the application of waste-water clarification sediment as fertilizer. M. STRELL. *Munich. Landw. Vers. Sta.* 90, 257(1917); *Biedermanns Zentr.* 47, 311-3(1918).—"Hawin" is a black-brown pasty mass obtained by the treatment of brown coal with NaOH soln. It dissolves in  $\text{H}_2\text{O}$  forming a deep brown colloidal soln. When 2-3 cc. of a 10% soln. of "hawin" and 1.5 cc. of a 10% soln. of  $\text{Al}_2(\text{SO}_4)_3$  are added to a l. of the water coarse flocculent particles form immediately and envelop the finest and apparently dissolved org. matter of the water and carry it to the bottom. The sediment settled in 10 min. is voluminous but is easily filtered, washed and dried. The study of the influence of the "hawin" soln. upon the nitrifiability of org. N compds. showed a favorable action especially with respect to the activity of the nitrite-forming bacteria. Nitrates could be demonstrated as present in the filtrates of the "hawin"

sediment but not in such const. quantities as nitrites. The nitrification of org. N compds. such as are present in large amts. in waste waters and in stable manures is decidedly hastened by the admixt. of humus-like substances. ALBERT R. MERZ.

**Fumigation of Cattleya orchids with hydrocyanic-acid gas.** E. R. SASSCER AND H. F. DIETRZ. Federal Horticultural Board. *J. Agr. Research* 15, 263-9(1918).—The larvae of the black walnut worm were placed in a variety of containers consisting of multiple coverings of cardboard, pill-boxes, sacks, etc., and subjected to fumigation with HCN gas under vacuum conditions, a dosage of one ounce of NaCN per 100 cu. ft. being employed. All larvae were killed. To det. whether such fumigation is harmful to Cattleya orchids, expts. were carried out with a large number of sound and damaged orchids, under varying conditions of moisture, and wrapping. While the fumigated plants lost their leaves more rapidly than the unfumigated plants, it was mostly the old leaves that fell and the fumigation is not responsible for the appearance of black or yellow areas on the plants and does not injure the bulb. Moisture was found to have no influence on the effect of HCN upon the plants. In some cases the HCN seemed actually to accelerate the growth. R. N. HARGER.

Potash content of blast furnace charges (GELLERT) 18. The Croydon and Wolverhampton sewage experiments (WILCOX) 14.

VOORHEES, EDWIN B.: *Fertilizers*. New Ed. New York: The Macmillan Co. \$1.50. Cf. C. A. 10, 3133.

**Fertilizer.** L. L. JACKSON. U. S. 1,289,789, Dec. 31. Feldspar is digested with an excess of lime and with about six times as much  $H_2O$  as lime at a temp. of about  $95^\circ$  for 10 hrs. The solids and liquid from the digestion are sepd. by filtration and the soln. is treated with  $CO_2$  and evapd. to dryness. The filter cake is treated with sufficient  $CO_2$  to combine with the  $Ca(OH)_2$  which it contains and in washing and further treatment Al compds. present are converted into  $Al(OH)_3$ . Dried alkali metal salts from the soln. first obtained are mixed with the product containing  $CaCO_3$  and  $Al(OH)_3$  and the mixt. may be used as a fertilizer. The solids from the digestion of the feldspar may be treated with waste  $H_2SO_4$  or  $NaHSO_4$  (instead of  $CO_2$ ) to convert the  $Ca(OH)_2$  into  $CaSO_4$ ,  $Na_2SO_4$  being recovered as a by-product with subsequent formation of Na alum.

**Fumigants.** E. W. BLACKER. Brit. 121,265, Sept. 19, 1918. A fumigant for destroying rabbits, rats, wasps, etc., consists of 2 oz. powdered S, 2 oz. saltpeter, 0.5 oz. turpentine or paraffin oil, and 0.5 oz. grease or treacle, mixed together to form a paste. The compn. may be spread on a small sheet of canvas, etc., which is then rolled up into a cartridge and tied round with string.

## 16. FERMENTED AND DISTILLED LIQUORS.

ROBERT WAHL.

**Detection of added water in wines.** W. I. BARAGIOLA. *Schweiz. Apoth. Ztg.* 56, 537-40(1918).—B. gives in detail the method of Tissier and François (C. A. 8, 3481).

and a brief note of U. Pratolongo (*Stas. sper. agr. ital.* 51, 56-60(1918); cf. *C. A.* 12, 2107). In the latter method, 2 samples of wine are satd., 1 with  $\text{KHC}_4\text{H}_4\text{O}_6$ , the other with  $\text{CaC}_4\text{H}_4\text{O}_6$ , allowed to stand for 30 min. at 50 to 60°, cooled and (a) the amt. of absorbed  $\text{KHC}_4\text{H}_4\text{O}_6$  is detd. by titration of total acid before and after treatment and (b) the amt. of  $\text{CaC}_4\text{H}_4\text{O}_6$  by gravimetric detn. of Ca before and after the satn. expt.

S. WALDBOTT.

**Reducing the acidity of wines with dipotassium tartrate.** W. I. BARAGIOLA. *Mitt. Lebensm. Hyg.* 9, 285-7(1918).—The amt. of di-K tartrate necessary to lower the dissociation of the tartaric acid in wines enough to change the taste is not enough to ppt. acid K tartrate, but it is enough to make the total tartaric acid value greater than 45% of the non-volatile acid. This might make the wine appear to be dild. and treated with free tartaric acid.

H. E. WOODWARD.

**Extract of beer.** H. HEUSER. U. S. 1,290,191, Jan. 7. An ext. produced by fermenting a grain mixt. or mash and concg. *in vacuo* is cooled to yeast-fermentation temp. and fermented with yeast and yeast nutrients with stirring to expedite fermentation. A large quantity of yeast is used and the proportion of added fermentable carbohydrates is adjusted to control the content of alc. in the product as desired. The ext. is charged with  $\text{CO}_2$  and, for use, it may be dild. with  $\text{H}_2\text{O}$  to obtain a beverage of low alc. content but otherwise generally resembling ordinary beer. U. S. 1,290,192 describes the treatment of an unfermented beer wort, containing 7% fermentable and 7% unfermentable substances, with 1 lb. of thick-fluid yeast to the bbl. and fermenting at a temp. of about 10°. After the described degree of fermentation, fermentation is arrested by filtering out the yeast, and the wort is concd. to a sirupy consistency *in vacuo*. The concd. ext. is then subjected to a second fermentation with yeast as in the process of the preceding pat.

## 17. PHARMACEUTICAL CHEMISTRY:

W. O. EMERY.

**The pharmaceutical chemist and the scope of his work.** FRANK O. TAYLOR. *J. Ind. Eng. Chem.* 11, 239-42(1919).—An address.

E. J. C.

**Essence of shuei flower (*Jasminum odoratissimum*, L.).** RIKITA TSUCHIHASHI AND SAICHI TASAKI. *J. Chem. Ind. (Japan)* 21, 1117(1918).—This flower, which is cultivated in Formosa, is noted for its fragrancy. From 90 kg. of fresh flowers 250 g. or 0.277% of essence were obtained by extn. with petr.-ether. The essence was sepd. into an oil (yield 0.116%) and a so-called flower wax (yield 0.166%). The enfleurage process was tried but was not successful. *Shuei flower oil* is reddish brown, has  $d_{15}^{20}$  0.9309,  $n_D^{18}$  1.4845,  $[\alpha]_D^{15}$  + 5.64, acid no. 5.85, sapon. no. 92.25, sapon. no. after acetylation 186.20. The oil was fractionated by distn. under reduced pressure. About 57% came over between 170 and 200° at a pressure of 3.5 to 4 mm. Eleven fractions are described. The compn. is approx. as follows: *d*-Linalool 6%, *d*-linalool acetate 6%, benzyl alc. 1.6%, benzyl acetate 6%, indole and methyl anthranilate 10% and high-boiling parts [sesquiterpene alc. or diterpene alc. (?) ] 57%. *Shuei flower oil* differs from the flower oil of *Jasminum grandiflorum*, L, described by Hesse and Müller (*Ber.* 34, 2929(1901)). *Shuei flower wax* has  $d_{15}^{100}$  0.8259,  $n_D^{60}$  1.4622,  $[\alpha]_D^{18}$  + 0.11, acid no. 1.25, sapon. no. 67.53, unsapon. matter 67.07%, I no. 100.0 (Hüble), R.-M. no. 1.0 and m. 45-57°. It contains 67% of triacontane,  $\text{C}_{30}\text{H}_{62}$ .

E. J. C.

**Substitute for cacao butter for making cast suppositories.** LEO BEHRBALK. *Pharm. Post* 51, 562(1918); *Chem. Zentr.* 1918, II, 760.—A mixt. which can be used for

making cast, but not pressed, suppositories consists of 1 part spermaceti and 3 parts olive oil. It m.  $37.2^{\circ}$ . C. O. EWING.

Is the introduction of tests of glassware necessary in the forthcoming German pharmacopeia? LUDWIG KROEBER. *Pharm. Zentralhalle* 59, 223-7, 233-7(1918); *Chem. Zentr.* 1918, II, 759.—Tests for glassware in the next Ger. Pharm. are desirable. A quick rough test for sol. alkali follows: Place 100 cc.  $H_2O$  in the vessel to be tested, add 2-3 drops of alc. phenolphthalein soln., and set aside 1 hr. The soln. should not show more than a bluish rose color and should not require over 2-3 drops 0.1 N HCl to decolorize. Anneller's narcotine-HCl test is more accurate; the vessel to be tested is filled with a 0.1% soln. of narcotine-HCl and set aside; at room temp. medicine bottles should give no ppt. or, at most, traces only of a flocculent ppt. in 0.25 hr.; under no circumstances should a cloud-like agglomerate be formed. Ampoules and measuring app. should not show more than traces of a flocculent ppt. in 0.5 hr. and the ppt. should not increase in a 2nd 0.5 hr. C. O. EWING.

Disadvantage of using heat in making *sapo mollis*, U. S. P. L. STEMPLE. *Merck's Report* 28, 17(1919).—In order to avoid the frothing and the danger of ignition of the alc. in the prepn. of *sapo mollis*, the U. S. P. process is modified as follows: Dissolve the KOH in the  $H_2O$ , add the alc. and mix well; then add the oil in several portions and stir until the soap assumes the consistency of a paste. The heat of reaction is sufficient for the process. The process can also be used in the prepn. of liquor cresolis compositus; the soap is first made and while still warm is dissolved in the cresol. C. O. EWING.

Acetylsalicylic acid. H. L. DAHM. *J. Ind. Eng. Chem.* 11, 29-30(1919).—The work is summarized as follows: A modification of the usual U. S. P. method of taking m. p., applicable to acetylsalicylic acid, is given. A set of permanent color standards for use in detg. the approximate amts. of salicylic acid in acetylsalicylic acid, with directions for prepn., is described. Results of previous investigators as to quality and purity of Am. and foreign aspirin were confirmed, by tests made over a period of 1 year. W. O. E.

Alkaloids of opium. D. B. DORR. *J. Soc. Chem. Ind.* 37, 430-1R(1919).—A brief description of 2 leading methods for isolating the alkaloids from opium, with especial reference to morphine, codeine, thebaine, narcotine, papaverine and narceine. W. O. E.

Physiological action of essential oils. I, II. S. FURUKAWA. *J. Tokyo Chem. Soc.* 39, 584-660, 809-45(1918).—The relation between chem. constitution and physiol. action was studied on a large number of perfumes and essential oils. Alicyclic alcs. which contain the CHOH group and their esters show a cooling taste. The lower aldehydes, alcs. and acids show cool, warm and acidic tastes, resp., and these tastes change to astringent in a higher homolog of each substance. Aromatic hydrocarbons and ketones show stimulus and bitter taste resp. A loach was kept in perfume solns. of various concns. for 24 hrs. and the toxic and narcotic actions of the perfumes were observed. In a homologous series, the toxic effect is decreased with increasing mol. wt. of the substance. The narcotic effect, however, is increased. In general, the total physiol. action, that is, the sum of both toxic and narcotic effects, is proportional to the mol. magnitude, within a certain limit, above which the soly. in  $H_2O$  or lipoids decreases suddenly. The author has extended his idea exptly. on the theory of narcosis and also on the physiol. meaning of perfume in a plant. S. KOMATSU.

Mode of mercurial embalming in the medieval epoch. GEORGES-A. LEROY. *Compt. rend.* 167, 996-8(1918).—In the museum of antiquities at Rouen are remains of John of Lancaster, Duke of Bedford, who died in 1435, consisting of a lock of hair

and about 50 g. of a blackish solid containing globules of Hg. These remains were removed from a grave in the cathedral of Rouen in 1866, and were at that time examd. by J. Girardin, who reported the compn. as Hg 11.25, matter sol. in water (including neither Cl nor  $\text{H}_2\text{SO}_4$ ) 11.33, balsamic resin having the characters of benzoin 8.20, "matieres org. insol. azotique (sic)" 59.00, water and loss 10.20. Girardin concluded that neither  $\text{HgCl}_2$  nor  $\text{HgSO}_4$  was employed, but that the metallic Hg resulted from the use of  $\text{HgO}$ . Twenty years later he admitted that the Hg was probably used as  $\text{HgCl}_2$ . Le Roy's study gave the following results: The embalming paste is a dry, black, friable, and spongy solid, sp. gr. 1.214, with globules of Hg disseminated throughout. Chem. analysis shows a neutral reaction to turnesole,  $\text{H}_2\text{O}$  at  $105^\circ$  9.90,  $\text{Et}_2\text{O}$  ext. 1.76, alc. ext. 2.68,  $\text{H}_2\text{O}$  ext. 3.44, mineral matter 30.60, matter volatile at red heat 69.40, insol. in  $\text{H}_2\text{O}$  43.65, Hg 8.03, org. N 1.93, water-sol. N 0.189,  $\text{NH}_3$  0.017, nitrates chlorides and sulfates in traces, carbonates, tannates and cupro-potassic reducing substances absent. The 30.60% of mineral matter contained  $\text{CaSO}_4$  0.72 with traces of chlorides; 11.948 sol. in HCl consisting of combined  $\text{P}_2\text{O}_5$  0.664, combined  $\text{SO}_3$  0.998,  $\text{Al}_2\text{O}_3$  4.38,  $\text{Fe}_2\text{O}_3$  0.420,  $\text{CaO}$  2.224,  $\text{MgO}$  0.202,  $\text{Na}_2\text{O}$  1.481,  $\text{K}_2\text{O}$  0.859. The 18.552% insol. in HCl contained  $\text{SiO}_2$  17.685,  $\text{Al}_2\text{O}_3$  0.660,  $\text{Fe}_2\text{O}_3$  0.05,  $\text{CaO}$  0.257. These results are discussed at length and synthetic expts. were made in an attempt to imitate some of the conditions under which the embalming probably took place. The final conclusions are that the Hg was employed in the metallic state as a "balsamo-mercurial unguent."

L. W. RIGGS.

**Trade in cinchona bark.** ANON. *Bull. Imp. Inst.* 16, 370-88(1918).—This is for the most part an article on the future of the trade in cinchona bark and is largely of economic interest. Two samples of the bark from St. Helena are described in detail and analyses are given of bark as received and of moisture-free bark. The total alkaloid (dry bark) was 9.2 and 9.3%. The yield of crystd. quinine sulfate was 9.1 and 5.1%, which are equiv. to 6.7 and 3.7% of anhydrous quinine. Analyses of 4 samples from East Africa also are reported. One of these (*Hybrid Cinchona ledgeriana* x *C. succirubra*) contained 8.41% quinine. There was no cinchonidine present.

R. L. SIBLEY.

**Strophanthus seeds and the galenical preparations made therefrom.** J. BLOMBERG, JR. *The Hague. Pharm. Weekblad* 55, 1587-97(1918).—The seeds of 3 distinct varieties of *Strophanthus* (*S. kombé*, *S. hispidus* and *S. gratus*) are used in pharmacy. There is considerable confusion among various pharmacopeias, chiefly between *S. Kombé* and *S. hispidus*. All three are used by African natives as arrow poisons, owing to their heart action. Unless fat-free, the seeds yield a tincture which causes diarrhea; yet only the U. S. P. IX and the Brit. Pharm. of 1914 require fat extn. before making the tincture. The seeds contain 35-45% of fat and are difficult to powder; the coarse powder from the 1st extn. must be dried, ground and extd. a 2nd time to ensure complete extn. Dry  $\text{Et}_2\text{O}$  or a high or low boiling petroleum ether may be used without affecting the strophanthin content. The color test for strophanthin with  $\text{H}_2\text{SO}_4$  is best carried out by dilg. the tincture with 10 vols. of  $\text{H}_2\text{O}$  and testing with 75%  $\text{H}_2\text{SO}_4$  at room temp. The inversion of strophanthin to insol. strophanthidin by acids can be used as a qual. or as a quant. test. The wt. of the residue after drying tincture of strophanthin varies so much that it is impractical to demand conformity to any standard in this respect. Though the tincture has no diuretic properties, the aq. ext. of *S. kombé* seeds is strongly diuretic. This is due to a mixt. of 2 saponins, of which 1 is acid and 1 is neutral. This aq. ext. has therapeutic value and deserves thorough clinical study. The aq.-alc. ext., given in conjunction with dionine or belladonna, gives results in some heart diseases which can be obtained in no other way.

JULIAN F. SMITH.

**Iodized chloroform in war surgery.** A. CHASSEVANT. *Union pharm.* 1918, 26; *Schweis. Apoth. Ztg.* 56, 581-3(1918).—A (violet) soln. of I 1 g., in  $\text{CHCl}_3$  30 g. is antiseptic without being caustic, and should replace the brown I solns., especially tincture of I, which are caustic and produce necrosis of the living cells. The  $\text{CHCl}_3$  soln. of I is useful in treating furunculosis and anthrax, suppurating wounds, burns, varicose ulcers and may be used as a prophylactic in diphtheria and cerebrospinal meningitis, since it is well supported by the mucous membranes. In wound treatment, use a protective dressing consisting of a mixt. of paraffin, white wax and spermaceti, equal wts., previously warmed to 50°.

S. WALDBOTT.

**Opium cultivation in South Serbia.** J. FRUSCHKOOGORAZ. *Schweis. Apoth. Ztg.* 56, 593-4(1918).—The greater part of "Salonichi opium" (C. A. 12, 2655) is cultivated in South Serbia. The best yield per hectare is 16 kg. In 1915 the total production was 125,000 kg.

S. WALDBOTT.

**A substitute for castor oil.** ANON. *Pharm. J.* 101, 95(1918).—"Oil of cavele," obtained from *Omphalea megacarpa* growing in Brazil, is suggested as a substitute. It has a straw color and a slight, not unpleasant odor. It also has diuretic properties, is non-irritant, and its cathartic activity does not decrease with age. Its chem. const. differ widely from those of castor oil. It is optically inactive not, viscous, and only slightly sol. in  $\text{EtOH}$ .

S. WALDBOTT.

**New method of extraction of alkaloids.** L. REUTTER. *Schweis. Apoth. Ztg.* 56, 668-71(1918).—The method consists in replacing the strong mineral acids by  $\text{AcOH}$ , citric, tartaric, oxalic or  $\beta$ -naphthalenesulfonic acids. *General procedure:* Treat 50 g. of the powdered drug with 200 g. of boiling  $\text{H}_2\text{O}$  containing 5 g. of the acid, filter hot, decant from the sepd. oil or resin, ext. remaining traces with  $\text{Et}_2\text{O}$  or petroleum ether, evap. the soln. to small bulk and ppt. the alkaloid by a suitable base. Redissolve and isolate the pure alkaloid by usual methods. Analytical results of the examn. of 26 drugs with each of the 5 acids are tabulated; close agreement is shown.

S. W.

**Ripe and unripe poppy capsules.** ZÖRNIG. *Schweis. Apoth. Ztg.* 56, 549-53(1918).—The use of "tea" from finely cut, ripe poppy capsules for small children is to be condemned, because alkaloids are still present in ripe capsules (C. A. 2, 886), and unripe fragments may be present. The ripe and unripe may be distinguished by the microscope (C. A. 8, 1641). The article should be eliminated from all, including the Swiss, pharmacopeias.

S. WALDBOTT.

**The seeds of *Ilex paraguariensis* St. Hilaire.** A. LENDNER. Geneva. *Schweis. Apoth. Ztg.* 56, 565-9(1918).—Germination expts. made on seeds brought by Chodat from Argentine in 1914 were but partly successful. The fruits, seeds and process of germination are described, also the structural characters involved (cf. C. A. 6, 2120). The seeds contained  $\text{H}_2\text{O}$  7.06, fatty matter 16.18, caffeine 0.17% by Burmann's method (C. A. 4, 1711; 5, 1949). Microsublimation readily shows the presence of caffeine.

S. WALDBOTT.

**"Ghassoul."** E. WILCZEK. *Schweis. Apoth. Ztg.* 56, 521-2(1918).—An Abyssinian drug, consisting of a coarse powder mixed with stems and ripe fruits of an undetd. species of *Mesembrianthemum*, and claimed to be a substitute for soap. Seeds from the fruits were planted in Geneva and Lausanne, and produced vigorous plants of *M. nodiflorum* and *M. crystallinum*. The chem. properties were not detd.

S. WALDBOTT.

**The deterioration of tincture of digitalis.** P. S. PITTENGER. *J. Am. Pharm. Assoc.* 7, 1031-4(1918); cf. C. A. 12, 1105.—During a storage period of from 9 to 13 mo., 43 samples were tested at intervals. The av. loss was 18.8%. The av. deterioration of 38 samples during the first 3 or 4 mo. was 4% per mo. The av. deterioration

of 32 samples after the first 3 or 4 mo. was 2.4% per mo. The rate of loss varies greatly with different lots, some deteriorating very rapidly and a few apparently not at all.

T. LYNTON BRIGGS.

The progress of applied chemistry in Great Britain during the war. RICHARD B. PILCHER AND FRANK BUTLER-JONES. *Rev. chim. ind.* 27, 214-9(1918).

E. H.

Report of the Patent Committee to the National Research Council. L. H. BAEKELAND, *et al.* *J. Ind. Eng. Chem.* 11, 250-3(1919).—Reforms are recommended.

E. J. C.

The needs of the U. S. Patent Office. THOMAS EWING. *J. Ind. Eng. Chem.* 11, 237-9(1919).—An address.

E. J. C.

More detailed statistics of chemical commodities. *J. Ind. Eng. Chem.* 11, 257-63(1919).—Part of a detailed report of a Committee on Reclassification of Commodities Imported and Exported made up of representatives of the Bur. of Foreign and Domestic Commerce, the Census of Manufactures, the Treasury, the Shipping Board, the Tariff Commission and the War Trade Board. Besides the main groupings in the classification there is given the classification of the main grouping "8-Chemicals and Chemical Products."

E. J. C.

Manufacture of hydrocyanic acid. H. A. PELTON AND M. W. SWARTZ. *Chem. Met. Eng.* 20, 165-6(1919).—An exptl. installation is described. A 35% aq. soln. of NaCN is run into an excess of 39° Bé H<sub>2</sub>SO<sub>4</sub> in a steam-jacketed reaction kettle provided with an agitator. The temp. is allowed to rise to 70° while the cyanide is being run in, and the mixt. is then brought to boiling. HCN and water vapor are distd. off, the latter being returned to the reaction kettle by a reflux condenser cooled with ice. The HCN passes through and is liquefied in a second condenser cooled with ice, and collected in cold steel cylinders. The product should be 90-95% pure. An av. yield of 78% of the theoretical is obtained, at an approx. total cost of \$1.074 per lb. of HCN produced.

E. M. BAKER.

Some observations on sulfuric acid plants (new and old). VI. "P." *Gas World* 69 (Coking and By-products Sec.), No. 1785, 14-5(1918); cf. *C. A.* 12, 2429.—The combustion of spent oxide is effected either in burners operated by hand or mechanically. The advantages of the former are: (1) Absence of mechanical defects, (2) the burned oxide contains a larger proportion of sol. Fe salts, which favors its reuse for gas purification, (3) water-white acid can be produced, owing to the absence of dust, (4) saving of initial capital outlay, (5) no necessity to screen the spent oxide. The advantages of the latter are: (1) greater regularity in compn. of gas. (2) S more effectually removed by combustion. The costs of operation of either type are almost

identical. Four types of hand-operated burners are diagrammed and the methods of working described. J. L. WILBY.

**Future of the barium industry.** WM. H. ROLLIN. *Chem. Met. Eng.* 20, 163-4 (1919).—To put the infant Ba industry on a sound commercial basis will require a protective tariff, reduced freight rates, and the right of producers to organize.

E. M. BAKER.

**Sodium salts in 1917.** ROGER C. WELLS. U. S. Geol. Survey, *Mineral Resources of U. S., 1917*, Part II, 305-41 (preprint No. 23, published Jan. 27, 1919). E. H.

**Potash content of blast-furnace charges.** N. H. GILLERT. *Iron Age* 103, 355-6 (1919).—The Fe ores ordinarily used in blast-furnaces in the U. S. contain from 0.29 to 2.07%  $K_2O$ . It is believed, however, that most of the Lake ores do not run over 0.3%. Foreign ores run high in potash, none of the Brazilian ores examd. containing less than 1%  $K_2O$ . The Alabama ores are comparatively rich in potash, even the brown ores running as high as 1.5%  $K_2O$ , while it is known that the gray hematites of this region run between 1 and 3%, although the latter have not yet been used extensively in furnaces. The cokes examd. run between 0.078 and 0.2%  $K_2O$ , while the limestone seems to run between 0.36 and 0.41%. Although the  $K_2O$  content of the burden may vary from a very small amt. to a comparatively large amt., the total quantity contained in the charge during 24 hrs. operation is considerable. It is computed that in 1915 there was charged into the blast furnaces of the U. S. about 305,000 tons of  $K_2O$ . The max. annual consumption of potash for the period 1905-14 was 279,780 net tons, in 1910, while the average amt. was 198,636 tons. The figures given for the possible potash supply from blast furnaces are based on the lowest content actually found. A much larger amt. is probably actually charged. It is believed that between 40 and 50% of the potash charged can be recovered. The device that can most successfully collect it is the Cottrell elec. precipitator. Expts. on a semi-commercial scale indicate that such a collection is possible.

A. L. FIELD.

**Potash discovery in Sicily.** ANON. *J. Ind. Eng. Chem.* 11, 246(1919).—It is reported that rich potash deposits have been found in the province of Cattanisetta, Sicily.

E. J. C.

**The present status of nitrogen fixation.** ALFRED H. WHITE. *J. Ind. Eng. Chem.* 11, 231-7(1919).—An address.

E. J. C.

**American sulfur industry expanding.** ANON. *Chem. Met. Eng.* 20, 186-8(1919).—The Texas Gulf Sulphur Co. is erecting a plant to mine sulfur under the Frasch patents from the Matagorda dome (Texas). Production of 1000 tons daily should start in April. The S is melted and forced to the surface by pumping down water at 163°. The fuel efficiency is less than 3%, based on the heat necessary to melt the S. Oil-fired boilers are used; about 2000 barrels of fuel oil and 4,000,000 gal. of feed water are required daily. The equipment of boilers, pumps, etc. is described.

E. M. BAKER.

**Preparation of crucible graphite.** G. D. DUB. *Bur. Mines War Minerals Invest. Ser.* 1918, No. 3, 24 pp.—A detailed description, with numerous figures, flow sheets, analytical and other data, of graphite investigations made by the Bureau in connection with the war minerals investigations. The establishment of a permanent domestic industry is discussed; the methods used in the Alabama, New York, Pennsylvania, and Texas fields, and the recovery of graphite from "kish" are described in detail; exptl. work on concn. and refining and on crucible manuf. are briefly outlined. Methods of sampling and of analysis (detn. of moisture, volatile matter, ash, and graphitic C by difference) are described. As a tentative specification for No. 1 flake graphite, it is recommended: (1) that the graphitic C content be not less than 85% (by graphitic

C is tentatively meant the C remaining after the dried sample has been burned in a covered crucible for 3 min. at 800°); (2) that the screen analysis show (figures represent cumulative %) over 35 standard mesh, 3; over 65 standard mesh, 50; over 100 standard mesh, 100. Results reported of complete analysis of 6 samples of domestic and 1 sample of Ceylon graphite indicate that the amt. of deleterious impurities in domestic flake graphite is small. Taking the sample of Ceylon graphite as a criterion, chemically, domestic graphite compares favorably with same. The report concludes with a discussion of the present status of the graphite-mining industry. F. W. SMITHER.

**British Admiralty hydrogen gas plant.** ANON. *Engineering* 107, 103(1919). —The plant operates the Jaubert process, which consists in the decompn. of Si alloys obtained in the elec. furnace, such as ferro-, or mangano-silicon, or even spiegel, by a 35 to 40% NaOH soln. The alkali soln. having a high b. p., all of the heat generated by the reaction in the combination of the Si with the alkali is retained in the soln. itself, thus doing away with external heating. The operation of the plant is as follows: To H<sub>2</sub>O contained in a vat, 1.5 to 2 times its wt. of soda is added, dissolution being aided by means of a stirring device. The heat generated raises the temp. of the soln. to 60 to 80°. The soln. is then run into the gas generator, which it should reach at a temp. sufficient to start the reaction on contact with the Si alloy. The "planetary stirrer" causes the alloy powder falling from the hopper-shaped receiver to come into intimate contact with the NaOH soln., and prevents it from accumulating in the center of the generator. The H gas, which is evolved at a high temp., flows into a scrubber condenser, and thence through a pipe line for utilization. The first set of app. installed yielded 60,035 cu. ft. H per hr. H. JERMAIN CREIGHTON.

ROUET, H. AND COTTO, F.: *Le controle technique a l'usine, a l'usage des controleurs, controleurs et ouvriers. Métaux.* Paris: H. Dunod et E. Pinat. 101 pp.

**Concentrating sulfuric acid.** H. V. WELCH. U. S. 1,289,984, Dec. 31. The method described is adapted for the concn. of the dil. H<sub>2</sub>SO<sub>4</sub> resulting from the manuf. of nitrocellulose and nitroglycerin or of dil. chamber acid produced in the manuf. of H<sub>2</sub>SO<sub>4</sub> by the chamber process. All of the dil. acid is converted into the vapor phase and then by cooling to a certain detd. degree a cloud of acid of definite strength is formed and the particles of this cloud are collected by elec. pptn. The temps. of cooling and the corresponding strengths of acid obtained are: 260–280° for 90% acid; 200–210° for 80% acid and 165–175° for 70% acid. Solns. containing HCl as well as H<sub>2</sub>SO<sub>4</sub> and H<sub>2</sub>O may be similarly treated to obtain H<sub>2</sub>SO<sub>4</sub> of a desired concn. Practically complete recovery of the acid is effected.

**Burning sulfur.** G. F. HURT. U. S. 1,289,783, Dec. 31. In burning S for the manuf. of SO<sub>2</sub> for making H<sub>2</sub>SO<sub>4</sub>, a pool of molten S is maintained in the burner and as the S in the pool is burned its combustion is facilitated by spraying a portion of the molten S upward from the pool into an atm. which will support its combustion. The pat. illustrates and describes an app. for carrying out this method.

**Dehydrating chlorides of rare earth metals.** C. W. BALKE. U. S. 1,289,079, Dec. 31. Anhydrous chlorides of rare earth metals are prepd. by adding NH<sub>4</sub>Cl to a soln. of the rare earth chlorides, crystg. out the mixed chlorides, evapg. to dryness and slowly raising the temp. to a dull red heat in the presence of a current of HCl until all the NH<sub>4</sub>Cl has been driven off.

**Thorium salts.** LINDSAY LIGHT CO. Brit. 117,438, Nov. 26, 1917. Monazite sand is heated with strong H<sub>2</sub>SO<sub>4</sub>, a temp. of 175° being mentioned, to convert the Th and rare earths into sol. form, and the heating is then raised to 250–300° until the Th

alone has become insol. The mass is then cooled and stirred with  $H_2O$  and the insol. Th pyrophosphate in cryst. form is filtered off and may be further treated to obtain pure Th compds. It is claimed also that pure thorium pyrophosphate in this form may be made by heating Th sulfate and  $H_3PO_4$  at  $280^\circ$ .

**Freeing liquids from suspended particles.** V. M. GOLDSCHMIDT. Can. 188,808, Feb. 25, 1919. Solns. of salts of Fe and Ti are freed from suspended solid particles by pptg. S in the liquid and removing the solid particles. The pptn. may be accomplished by the oxidation of  $H_2S$  by means of a ferric salt. Cf. C. A. 12, 2114.

**Clarifying liquids.** TITAN CO. Brit. 121,457, Oct. 31, 1918. To assist the deposition of finely divided solids suspended in liquids, a ppt. of S is formed in the liquid which in settling brings down the suspended solid. The invention is particularly described with reference to removing hydrated  $SiO_2$  from a soln. containing ferrous and ferric sulfates and Ti sulfate, and it is suggested that the action is in part due to the electropositive and electronegative conditions of the  $SiO_2$  and the S, respectively. The S may be introduced as  $H_2S$ , which is oxidized in the liquid described by the  $Fe_2(SO_4)_3$ , but oxidizing reagents may be added when necessary.

**Recovering potassium compounds from silicates.** A. GRAUEL. U. S. 1,289,736, Dec. 31. Fumes from feldspar or similar silicates containing K, produced by heating the mineral silicate with  $CaCl_2$  or  $CaSO_4$  (depending on whether KCl or  $K_2SO_4$  is desired) are absorbed in a soln. which is preheated and maintained under pressure to facilitate the absorption and vapors from the absorption liquid are condensed to avoid loss.

**Apparatus for recovering potassium compounds from smoke and ash of vegetable materials.** H. M. HINER. U. S. 1,290,194, Jan. 7. Cotton bolls, hardwood sawdust or other vegetable materials may be burned in the app. to obtain K compds.

**Absorption of carbon dioxide from gaseous mixtures.** J. C. H. KRAMERS. U. S. 1,290,244, Jan. 7.  $CO_2$  from gaseous mixts. is absorbed in a soln. containing  $Na_2CO_3$  together with other salts such as NaCl or  $NaNO_3$  which raise the b. p. of the soln. and mixed with a sludge of  $MgCO_3$  or basic carbonates of Mg which improves the ability of the mixt. to absorb  $CO_2$ . The latter is recovered from the soln. by heating and the soln. may then be reused for absorbing additional  $CO_2$ .

**Apparatus for obtaining nitrogen and carbon dioxide from combustion gases.** C. D. McCOURT and C. ELLIS. U. S. 1,289,496, Dec. 31. An explosive mixt. of fuel gas and air is burned by surface combustion in a bed of refractory material in a boiler furnace, the gas and air being used in approx. combining proportions. Combustion gases from the furnace are led to an "economizer" wherein they are cooled and thence to an absorption device where the  $CO_2$  is taken up by carbonate liquor. Carbonate liquor from the absorption app. is passed through the economizer to preheat it and then to the boiler where the  $CO_2$  is driven off from the liquor. N in the decarbonated gas may be purified and converted into cyanamide.

**Drying precipitates, etc.** A. F. LAURIE. Brit. 121,372, Dec. 29, 1917. Materials pptd. or deposited from suspension in liquids are submitted to a low temp. to freeze the liquid content, and, during thawing the superfluous  $H_2O$  is removed by draining, by a vacuum filter, or by other means. The process is stated to be applicable to ppts. of a gelatinous character, ochres, chrome and Cd yellow, Prussian blue, and other pigments.

**Sulfur-burner.** H. C. ELLIS. U. S. 1,289,417, Dec. 31. The pat. relates to structural features of a S-burner built of reinforced concrete and fire-brick. It is especially intended for making  $SO_2$  to bleach grain.

**Pitch in filament form.** R. P. PERRY. U. S. 1,289,892, Dec. 31. Pitch is converted into filament form by placing molten pitch in a centrifugal machine with per-

forated walls and regulating the temp. of the pitch and the speed of the machine so that filaments of pitch extrude through the perforations of the walls. The pitch filaments may be coated with powdered soapstone to render them non-adherent and are suitable for use in making felted heat-insulating or packing material.

## 19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLEININGER.

**The presence of iron in the furnace atmosphere as a source of color in the manufacture of optical glass.** EDWARD W. WASHBURN. *J. Am. Ceram. Soc.* 1, 637-9 (1918).—It was first noticed that a heavy flint glass ( $n_D = 1.64$ ) was colorless when melted in an elec. furnace but decidedly greenish when melted in a gas furnace in the lab. Gas samples taken in a large furnace and directly over the pot distinctly showed the presence of Fe. Stirring the glass hastened the Fe contamination. The sources of Fe are chiefly (1) burners, (2) impurity in fire bricks. Using clay burners and coating the inside of the furnace wall with kaolin gave distinct improvement in color.

C. H. KERR.

**The effect of certain impurities in causing milkiness in optical glass.** Discussion by F. GELSTHARP of paper by C. N. FENNER AND J. B. FERGUSON. *J. Am. Ceram. Soc.* 1, 559-66 (1918); cf. *C. A.* 13, 368.—At Pittsburgh Plate Glass Co. the only glasses that showed milkiness were the borosilicate crown and dense flint. Impure  $K_2CO_3$  was not the cause because pure  $KNO_3$  was used. In the ordinary Na-Ca glasses milkiness may always be cured by a slight increase in alkali content. Milkiness in the optical glasses is also ascribed to deficiency in alkali due perhaps to volatilization under improper melting conditions. *Reply by Fenner and Ferguson:* Calculation and expts. relating to the optical glasses showed that conditions most favoring deficiency of alkali tended to lessen rather than increase milkiness. Curing milkiness by higher temps. also tends to refute Gelstharp. Final proof, however, is not claimed.

C. H. KERR.

**Expansion of glass in connection with its optical and thermal properties.** Masamichi So. *Proc. Tokyo Math. Phys. Soc.* [2] 9, 426-41 (1918).—A newly drawn and unannealed thin glass thread contracts in a longitudinal direction at a temperature just below that at which the glass becomes plastic. This is thought to be due to recovery from the strain. Heat is absorbed by the glass on reaching its plastic state. This is independent of any strain, and seems to be a phenomenon associated with the melting of one of the glass constituents. The electric resistance of glass falls logarithmically within a temperature range below its plastic state. This temperature range is lower than that at which the other two phenomena take place. F. P. PHELPS.

**Notes on the "Sang de Boeuf" and the copper-red Chinese glazes.** J. N. COLLIE. *Trans. Eng. Ceram. Soc.* 17, 379-84 (1918); cf. *C. A.* 11, 92.—It is impossible to say whether the red color of reduced Cu is due to a cuprous silicate or to colloidal Cu. The amt. of Cu in the Sang de Boeuf glaze is very small, probably under 1% CuO. There is somewhat more  $Fe_2O_3$ . Phosphates are absent and the glaze is the ordinary feldspathic glaze containing  $SiO_2$ ,  $Al_2O_3$ , CaO and alkali. Other types of copper reds were also made fully as brilliant as the best Sang de Boeuf but opaque. These are Pb glasses and glazes. A Roman Egyptian glass showed on analysis:  $SiO_2$  38.20, PbO 31.10, CuO 4.67,  $Al_2O_3 + Fe_2O_3$  2.10, MnO 0.10, CaO 8.15,  $K_2O$  0.61,  $Na_2O$  10.29,  $SnO_2$  0.70. An early Ming Chinese vase showed the following approximate analysis: PbO 28, CuO 2,  $Fe_2O_3$  2,  $P_2O_5$  trace. The historical descriptions are of great interest.

C. H. KERR.

**The control of luster in enamels.** HOMER F. STALEY. *J. Am. Ceram. Soc.* 1, 640-7 (1918).—Control of luster is very largely a control of crystn. Luster is helped

by increase in viscosity which is accomplished by increasing  $\text{SiO}_2$ , feldspar,  $\text{B}_2\text{O}_3$ , kaolin or any material which does not fuse or go into soln. in the enamel, or by decreasing fluxing oxides (except  $\text{B}_2\text{O}_3$ ) or fluorides. Since increase in concn. of any crystallizable material will obviously increase mattness, a decrease will help luster. Any delay in the enameling operation tends to spoil luster. S compds. especially from furnace gases are fatal to good luster. Materials of high  $n$  are obviously the more brilliant.

C. H. KERR.

A method for the graphic determination of quaternary mixtures. HORACE S. NEWMAN. *Trans. Eng. Ceram. Soc.* 17, 336-9(1918).—Pottery compns. usually contain ball clay, china clay, Cornish stone and flint and if only 3 variables are used an arbitrary relation of ball clay to china clay must be set. The variation in percentages of the 4 ingredients is shown on a square. For illustration, a square is divided into 25 smaller squares. At the top left corner, ball clay = 10 and decreases across the top, 8, 6, 4, 2 and 0 at each smaller square. In the same way, Cornish stone starts at 10 at the top right corner and decreases down the right edge, 8, 6, 4, 2 and 0. China clay starts at the bottom right corner (= 10) and decreases across the bottom, 8, 6, 4, 2 and 0. Flint starts at the bottom left corner (= 10) and decreases up the left edge, 8, 6, 4, 2 and 0. Any point then by reading across to the 4 edges (and multiplying each figure by 5) shows the % of each of the 4 ingredients. The limitations are (1) no mixt. with over 50% of any one ingredient can be shown but this limitation is not often important in pottery mixes, (2) no mixt. represented by opposite corners only can be shown. Examples are given.

C. H. KERR.

Some types of porcelain. F. H. RIDDLE AND W. W. McDANIEL. *J. Am. Ceram. Soc.* 1, 606-27(1918).—The object was to det. the burning range of porcelain bodies fired at or above cone 10 and having compns. covering the ordinary porcelain field. The range of mixts. is shown in the table.

| Clay %. | Feldspar %. | Whiting %. | Flint %. |
|---------|-------------|------------|----------|
| 45      | 16-30       | ...        | 39-25    |
| 50      | 16-30       | ...        | 34-20    |
| 55      | 14.5-28.5   | 1.5        | 29-15    |
| 60      | 14.5-28.5   | 1.5        | 24-10    |
| 70      | 10-28.5     | 1.5        | 18.5-0   |
| 75      | 10-23.5     | 1.5        | 13.5-0   |
| 80      | 10-18.5     | 1.5        | 8.5-9    |
| 85      | 13.5        | 1.5        | 0        |

The clay content was equal parts Georgia, Florida, N. Carolina, and Delaware kaolins. Where clay exceeded 55% the balance was calcined to cone 14 and dry ground to 120 mesh. Burning range was not much wider for low-feldspar than for high-feldspar bodies. The higher the clay content the less the effect of variations in flux. Results are discussed in detail. In a second series of mixts. the effect of ball clay was studied. As little as possible should be used. Adding small amts. (up to 1%  $\text{BaO}$ ) of  $\text{BaCO}_3$  had almost no effect.  $\text{CaO}$  assisted in vitrification but hastened overburning,  $\text{MgO}$  or dolomite was beneficial. Replacing quartz by a  $\text{SiO}_2$  equiv. of sillimanite made a good body, particularly where low coeff. expansion was desired. White color is secured by (1) using very pure material, (2) burning under reducing conditions, and (3) masking the yellow color by a blue stain.

C. H. KERR.

The standardization of tests for refractory materials. (Part I.) J. W. MELLOR. *Trans. Eng. Ceram. Soc.* 17, 300-30(1918); COSMO JOHNS, *Engineering* 106, 540-2, 569-72(1918).—An outline of a committee report on provisional specification governing methods of testing. 1. The analysis of fireclays, raw ganisters, quartzose rocks and manufactured products: Methods for hygroscopic  $\text{H}_2\text{O}$ , ignition loss,  $\text{SiO}_2$ ,  $\text{Al}_2\text{O}_3$ .

$\text{Fe}_2\text{O}_3$ ,  $\text{TiO}_2$ ,  $\text{CaO}$ ,  $\text{MgO}$ , and alkali are given in detail. *II. Analysis of dolomite and magnesite:* Methods are given for hygroscopic  $\text{H}_2\text{O}$ , ignition loss, alkali,  $\text{SiO}_2$ ,  $\text{Al}_2\text{O}_3$ ,  $\text{CaO}$ ,  $\text{MgO}$ ,  $\text{Fe}_2\text{O}_3$ ,  $\text{TiO}_2$ , P and S. *III. The identification of the various forms of  $\text{SiO}_2$  in  $\text{SiO}_2$  bricks:* Either thin sections or powders may be used; thin sections are best for study of cryst. form and habit. Optical characteristics and distinctions are discussed in detail. *IV. Porosity,  $\text{H}_2\text{O}$  absorption and sp. gr.:* For porosity detn. a 2" cube is dried at  $110^\circ$  for 2 hrs., soaked for several hrs., preferably overnight, in  $\text{H}_2\text{O}$  under reduced pressure and porosity is expressed as vol. % of the whole piece. With very dense pieces soaking must be continued several days to get duplicates to agree within 0.2% as required. Apparent sp. gr. is calcd. from the same data and real sp. gr. of powder detd. as usual. *V. Shrinkage in drying and burning:* Specimens  $4\frac{1}{2}" \times 1\frac{1}{8}" \times \frac{9}{16}"$  are dried at  $70-80^\circ$  for 4-5 hrs., and finally at  $110^\circ$ . Drying shrinkage is based on wet length. Burning rate should be not over 100° per hr. up to  $900^\circ$  and 200° per hr. above  $900^\circ$ . Burning shrinkage is expressed in terms of both wet and dry lengths. *VI. Tensile strength of dried clays:* The ordinary cement briquet shape is used and specimens are broken in the usual cement-testing machines. *VII. After-contraction or after-expansion:* Temps. of  $1410^\circ$  for firebricks and materials with under 80%  $\text{SiO}_2$  and  $1350^\circ$  for refractories with over 80%  $\text{SiO}_2$  are standard, and these temps. are held for 2 hrs. *VIII. Normal refractoriness:* A piece chipped to Seger cone shape and fused in a Hirsch or similar elec. furnace and compared with standard cones. Heating rate should be  $50^\circ$  per 5 min. until the first cone melts and  $20^\circ$  per 5 min. until the end. *IX. Load test:* Test pieces  $2" \times 2" \times 3\frac{1}{8}"$  are cut from bricks and tested on end in a furnace with lever attachment to apply load. The furnace is described in detail but the test is not. *X. Thermal expansion:* The Coppée app. is used, consisting of a horizontal cathetometer, with standard metric scale and a suitable furnace. Saw cuts are made in the edge of a standard brick,  $\frac{1}{8}"$  from each end and Pt wire with pointed ends inserted as measuring indices. Standard temps. are not given. *XI. Crushing strength cold:* The usual compression testing machines are suitable.

C. H. KERR.

Effect of load on the refractoriness of firebricks. J. W. MELLOR AND W. EMERY. *Trans. Eng. Ceram. Soc.* 17, 360-71(1918).—See C. A. 12, 2118.

C. H. KERR.

Report of committee C-8 on refractories. ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 287-92(1918).—A revision of details in the tentative method for ultimate chem. analysis given (cf. C. A. 12, 793). Load test method is also somewhat revized (cf. C. A., 12, 858), the chief changes being in substitution of a larger furnace testing 2 bricks at once and in the rate of heating of both  $\text{SiO}_2$  and clay bricks in the test.

C. H. KERR.

Tentative test for refractory materials under load at high temperatures. ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 573-7(1918).—Revision of former outline (cf. C. A. 12, 858 and preceding abstract).

C. H. K.

Tentative methods for the ultimate chemical analysis of refractory materials. ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 580-7(1918); cf. C. A. 12, 793, and 2nd abstract above.

C. H. KERR.

Refractory products. A. MALINOVSKY. *Chem. Met. Eng.* 19, 768-9(1918).—A general description of various types of refractories and an argument for the work of the Am. Ceram. Soc.

C. H. KERR.

Tentative test for slagging action of refractory materials. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 578-9(1918).—Drill cavities 2.5" diam.  $\times$  0.5" deep on the face of regular bricks. The standard slag (new compns. have since been decided upon) is ground to 40 mesh. The brick is heated in 5 hrs. or more to  $1350^\circ$ , 35 g. of slag

introduced and 1350° held for 2 hrs. Penetration is measured by a planimeter.

C. H. KERR.

**Refractories used in steel production.** ALLEYNE REYNOLDS. *Trans. Eng. Ceram. Soc.* 17, 385-458(1918).—A review of the various conditions surrounding the use of refractories in steel making and of the refractories used.

C. H. KERR.

**The constitution of silica bricks.** ALEXANDER SCOTT. *Trans. Eng. Ceram. Soc.* 17, 459-74(1918).—Impurity in raw material should be low, preferably under 5-6%. Requisite properties of good quartz rock are: (1) high  $\text{SiO}_2$  content, (2) presence of an amt. of impurity sufficient to accelerate quartz conversion but insufficient appreciably to lower the m. p., (3) structure that will give angular fragments on crushing. The structure of the original rock exerts a strong influence on cryst. conversion. A brick of which the hot end had been at about 1550° for many months showed the following percentages of (a) quartz, (b) cristobalite, (c) glass and (d) tridymite at the given distances from the hot end: 1 cm. (a) 0, (b) 1.9, (c) 6.7, (d) 91.4; at 12.5 cm. (a) 10.8, (b) + (c) 59.0, (d) 30.2; at 20 cm. (a) 20.4, (b) + (c) 71.1, (d) 8.5. In the cooler parts the material is mainly cristobalite. Evidence tends to prove that tridymite is the stable form up to 1550° at least. A piece of brick which was all tridymite was held for 2 weeks at 1530° and quenched. The tridymite was unchanged. Contamination of bricks during use may considerably alter the changes. In steel furnaces the roof bricks show the following zones: (1) a gray zone—the hottest end—showing very little trace of the original rock, (2) a black zone about 4-6 cm. deep partly structureless but showing some traces of the original fragments, (3) a broad band (7-10 cm.) of pale colored materials resembling the original mass but less distinct and (4) a red (cool) end with the extreme end unaltered. These parts are well described.

C. H. K.

**Silica products. I. Raw materials.** A. BIGOT. *Trans. Eng. Ceram. Soc.* 17, 259-66(1918).— $\text{SiO}_2$  bricks from the frieze of archers of the palace of Darius (at the Louvre) were made from quartz sand with a lime binder. Analysis showed:  $\text{SiO}_2$  89.10,  $\text{CaO}$  5.05,  $\text{MgO}$  0.62,  $\text{Al}_2\text{O}_3$  2.10,  $\text{Fe}_2\text{O}_3$  2.80. Some historical data are given, also methods and general data regarding the study of the raw materials by analytical, physical and microscopic methods.

C. H. KERR.

**The necessity for inspection and testing of refractory brick.** C. E. NESBITT AND M. L. BELL. *Proc. Am. Soc. Testing Materials* 18, Pt. II, 336-48(1918).—Specifications for refractory bricks specify nothing of importance. Tests must be rapid and show fitness for the particular use intended. For testing  $\text{SiO}_2$  brick for steel works use, tests of slag action, spalling and hot crushing are sufficient, while for clay brick, load, spalling and slagging tests are needed. Visual inspection is of utmost importance. In a tabulation of results in the spalling test on 5 successive shipments of one brand of  $\text{SiO}_2$  brick the loss varied from 11.72 to 40.80% in one lot and from 13.39 to 43.37% in another lot while av. for all shipments was about 25%. Similar variations are shown in the crushing and slag-penetration tests. Excellent pictures are shown.

C. H. KERR.

**Note on the microstructure of magnesite bricks.** ALEXANDER SCOTT. *Trans. Eng. Ceram. Soc.* 17, 475-85(1918).—In magnesite bricks there are two distinct types and gradations between these. In the first,  $\text{MgO}$  occurs as sharply defined polygonal crystals of periclase which form a reticulate aggregate. In the second type, the  $\text{MgO}$  appears as small, rounded crystals in a matrix usually crystalline. The first is found in bricks with  $\text{Fe}_2\text{O}_3$  as the main impurity while the second is more common where appreciable quantities of  $\text{CaO}$  and  $\text{SiO}_2$  are present.

C. H. KERR.

**Tentative methods for determining porosity and permanent volume change in refractory materials.** ANON. *Proc. Am. Soc. Testing Materials* 18, 588-91(1918).—

Test pieces  $2.5 \times 2.5 \times 1.25$ " are cut from standard bricks. Specimens are burned and trials drawn at each  $50^\circ$  interval from 1200 to  $1500^\circ$ . Tests are made in kerosene and under a vacuum of 24" for 24 hrs. at  $250^\circ$ . Calcns. of exterior vol., open pores, apparent sp. gr., true sp. gr., sealed pores and vol. shrinkage are shown. C. H. K.

**The new refractory and abrasive matter called corindite.** ALEXANDRE BIGOT. *Trans. Eng. Ceram. Soc.* 17, 267-70(1918); cf. C. A. 12, 2242.—Both the red and the white bauxite of southern France are fused by the Lecesne process (cf. C. A. 11, 1022, 2838; 12, 1240, 1591). Typical analyses of corindite prepared from (a) white bauxite and (b) red bauxite are:  $Al_2O_3$  (a) 68.80, (b) 69.25;  $TiO_2$  (a) 3.85, (b) 3.70;  $SiO_2$  (a) 21.40, (b) 3.00;  $Fe_2O_3$  (a) 5.25, (b) 23.35; C (a) 0.60, (b) 0.50; ign. loss (a) 0.10, (b) 0.15. The white is exceedingly refractory and the red is a good abrasive.

C. H. KERR.

**Tentative specifications for clay sewer pipe.** *Proc. Am. Soc. Testing Materials* 18, Pt. I, 542-54(1918)—Any special chem. requirements shall be stated in advance. Phys. tests shall include crushing, hydrostatic pressure and absorption. Over 20% failure of tested pieces shall cause rejection. Details of the tests are given. Sizes, with permissible variations are tabulated. Crushing strength must be 1430 lbs. per linear ft. for 6" internal diam. pipe, 1430 for 8", 1570 for 10", 1710 for 12", 1960 for 15", 2200 for 18", 2590 for 21", 3070 for 24", 3370 for 27", 3690 for 30", 3930 for 33", 4400 for 36", 4710 for 39", 5030 for 42".

C. H. KERR.

**Report of Committee C-10 on hollow building tile.** ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 294-6(1918).—Tabulations of results of compression tests and absorption tests made at the Univ. of Cal. and at the Univ. of Mich. are given but not discussed.

C. H. KERR.

**Tentative tests for molded insulating materials.** ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 694-706(1918).—The tests apply to all solid insulating materials formed in molds or between platens by the application of pressure, either with or without heat. For tensile strength, figure 8-shaped briquets are tested 1 hr. at  $10^\circ$  below the distortion point. For compression a 1" cube is tested at room temp. For transverse a bar  $1\frac{1}{2}$ " square  $\times$  5" long, supported 100 mm. apart is tested. Dielec. strength shall be tested on a cup shaped sample with  $2\frac{1}{2}$  mm. bottom. For distortion the  $1\frac{1}{2}$ " square  $\times$  5" long specimen is used. A special app. for applying load is described. The temp. is increased  $\frac{1}{2}^\circ$  per min. and distortion point is marked when the deflection at the center is 0.254 mm. Effect of  $H_2O$  is shown by immersion in  $H_2O$  for 100 hrs. at room temp.

C. H. KERR.

**The use of tunnel kilns for brick and other products of crude clays.** ELLIS LOVEJOY. *J. Am. Ceram. Soc.* 1, 628-36(1918).—The kiln is being thoroughly tried out but much must still be done before it will replace other types of continuous kilns. There are under construction or in operation 15 for white ware, porcelain, etc., 5 for refractories, 2 for building brick, and 7 have been abandoned as failures.

C. H. KERR.

**Ovens and kilns with a high thermal efficiency.** A. BIGOT. *Engineering* 107, 80-2(1919).—(1) *Industrial Lab. Kilns:* In expts. made in 1912 it was shown that adding a sheet-Fe recuperator to a Perrot kiln (cuts and description are given) the max. working temp. was increased from 1200 to  $1400^\circ$  and an oxidizing, reducing or neutral atm. could be maintained at will. In 1915 it was found that by surrounding the sheet-Fe recuperator with a good insulator the temp. was further increased from 1400 to  $1750^\circ$ , attainable in 5 hrs. However, the furnace lining melted and the sheet Fe rapidly burned out. Both were replaced by suitable refractories (which are not described). A new furnace of this sort has been built at the testing lab. of the Conservatoire National des Arts et Métiers. (2) *Industrial Kilns:* The same ideas are applicable to com.

kilns. Insulators like infusorial earth, light  $MgO$ , asbestos, etc., are not effective above  $800^{\circ}$  and should not be used above  $1000^{\circ}$ . For kiln walls ordinarily 27" thick the outer 18" may be replaced by 3" of insulating brick, since it shows only  $\frac{1}{6}$  the heat cond. Outside this a 1.8" layer of insulating powder should be used. Tests made on an intermittent kiln showed: before the above changes, temp.  $1230^{\circ}$  in 78 hrs.; after the change  $1465^{\circ}$  in 58 hrs. For kilns with movable bottoms the bottom plates should roll on refractory balls, these balls having 3 chief properties: (1) resistance to wear when hot or cold, (2) high crushing strength at various temps., (3) ability to withstand sudden temp. changes. No data regarding compns. or properties are given. Great claims are made for patented kilns which are illustrated and briefly described. It is claimed that the burning of  $SiO_2$  wares is solved. Low fuel consumption is especially claimed.

C. H. KERR.

**The dissociation of salt.** H. V. THOMPSON. *Trans. Eng. Ceram. Soc.* 17, 340-50 (1918).—At  $1113^{\circ}$  1 g. mol. of  $H_2O$  decomposed 0.37 g. mol. of  $NaCl$ . Preliminary expts. to show the action of  $NaCl$  and  $H_2O$  vapor on  $SiO_2$ ,  $Fe_2O_3$ ,  $Al_2O_3$  and clays are described.

C. H. KERR.

**Electricity in the ceramic arts.** J. P. ALEXANDER. *Gen. Elec. Rev.* 22, 113-6 (1919).—Descriptions of the various processes employed in the pottery industry and the advantages obtained by elec. drive, etc. Of particular interest to the chem. engineer.

C. G. F.

**Notes on the evolution of the ganister industry in the Sheffield district.** J. HOLLAND. *Trans. Eng. Ceram. Soc.* 17, 293-9 (1918).—A brief historical and general description.

C. H. KERR.

**The bending of easy-fired ware.** BERNARD MOORE. *Trans. Eng. Ceram. Soc.* 17, 351-9 (1918).—A pottery body is considered simply as an infusible framework and a fusible flux or matrix. The lower types of bodies, such as earthenware, are generally low in matrix and high in infusible framework while porcelain types are the reverse. But the kind of matrix is radically different, that of the earthenware type being much the more fusible. Eutectic compns. play an important role. Points to be considered are: (1) texture—fineness of grinding, (2) method of mixing, (3) uniform distribution of fine particles to avoid clumping, (4) early and steady vitrification of the matrix, (5) full contraction produced in the first fire if the body must withstand compression or tension at a high temp. in the second fire.

C. H. KERR.

**The deterioration of molds during storage.** J. W. MELLOR. *Trans. Eng. Ceram. Soc.* 17, 331-5 (1918).—The "fur" that grows on the molds "contains a considerable proportion of  $Na_2SO_4$  derived partly from sol. salts in the clay, partly from solns. of plaster of Paris in  $H_2O$ , and partly from the decompn. of  $Na_2CO_3$  and  $Na$  silicate by the  $CaSO_4$ ." Preventive precautions are (1) thorough drying before storing, (2) rapid drying in use so as to keep the crystals small, (3) storing in rooms that are warm and dry enough to prevent condensation during muggy weather.

C. H. KERR.

#### Tests of glassware (KROEBER) 17.

**Marking enameled ware.** W. J. KOHLER. U. S. 1,290,580, Jan. 7. Enameled ware is provided with a ground coat of binding material, heated to whiteness and then given a coat of powdered enamel, again heated to a white heat and given a second coat of powdered enamel, marked with enamel of different color and again heated to effect a smooth union of the different enamels.

**Refractory material for crucibles.** F. J. TONE. U. S. 1,289,578, Dec. 31. Crucibles are formed of a mixt. of natural or artificial graphite 40, fused cryst.  $Al_2O_3$  40 and plastic clay 20 parts. The crucibles formed have greater freedom from tendency

to split along cleavage planes than crucibles made from graphite and clay alone and will withstand sudden changes of temp. without cracking. They are well adapted for melting Fe or steel.

**Refractory material for crucibles.** F. J. TONE. U. S. 1,289,966, Dec. 31. A mixt. of graphite 40, zirconia 40 and plastic clay 20 parts is used for making crucibles, retorts, muffles or other refractory articles.

**Purifying fire-clay.** H. L. KOHLER. U. S. 1,290,241, Jan. 7. Finely divided clay is sepd. from heavy sands and feldspars by the action of air currents and is then subjected to a magnetic sepn. to purify it further.

---

## 20. CEMENT AND OTHER BUILDING MATERIALS.

---

C. N. WILEY.

**Cement in 1917.** ERNEST F. BURCHARD. With a section on concrete ships. ROBERT W. LESLEY. U. S. Geol. Survey, *Mineral Resources of U. S., 1917*, Pt. II, 343-80 (preprint No. 24, published Feb. 4, 1919); cf. C. A. 12, 615. E. H.

---

**BLANCHARD, ARTHUR H., et al.: American Highway Engineers' Handbook.** New York: John Wiley & Sons, Inc. 1683 pp. 55. For review see *Eng. News-Record* 82, 387(1919) or *Manufacturers Record* 75, 114(1919).

---

**Composition for covering cement surfaces.** C. P. ANDERSON. U. S. 1,290,035, Jan. 7. A compn. for covering cement surfaces for producing uniform architectural finishes is formed of ZnO 480 lbs., calcined plaster 180 lbs., ground asbestos 60 lbs., finely ground pumice stone 150 lbs., "prepared oil" 32 gals., turpentine oil 5 gals. and naphtha or benzine about 10 gals. The "prepared oil" is formed of boiled linseed oil 55, boiled China wood oil 35, litharge drier 20 and naphtha or benzine 90 parts. The compn. is applied to clean porous or roughened surfaces, with a brush, in the same manner as oil paints are applied. A somewhat porous coating is formed which permits passage of moisture through the material without forcing off the coating. Pigments may be added to the coating mixt. to give it any desired color.

**Pavement composition.** A. E. SCHUTTE. Can. 187,504, Nov. 19, 1918. A wear-resisting material free from dust filler is mixed with bituminous cement having asbestos fiber incorporated therewith.

**Insulating or building material from dolomite.** A. M. MITCHELL. U. S. 1,289,862, Dec. 31. Dolomite is crushed and heated sufficiently to dehydrate it, and then mixed with S and paraffin 2% while hot and cast in a mold under pressure to form an insulating or building material.

**Roofing material.** F. C. OVERBURG. Can. 188,744, Feb. 18, 1919. Flexible roofing is made by simultaneously impregnating sep. sheets of fibrous material with a water-proofing compd. supplying a layer of non-adhesive material between the sheets to prevent their adherence, then bringing the sheets into facial contact, coating the exterior of the sheets with a bituminous compd. and sepg. the sheets. App. is also specified.

**Asphaltic roofing.** H. R. WARDELL. U. S. 1,289,328, Dec. 31. Roofing material, which may be made of satd. felt with an asphalt surface, is coated, while its surface is hot, with particles of grit moistened with an asphalt solvent such as naphtha or gasoline.

## 21. FUELS, GAS, TAR AND COKE.

J. D. PENNOCK.

**Fuel economy in the boiler house.** I. JOHN B. C. KERSHAW. *Chem. Met. Eng.* 20, 176-8(1919).—K. emphasizes the importance of systematic control of waste gases in boiler plants and discusses details in installation and maintenance of automatic CO<sub>2</sub> recorders. Glass tubing connected by best red rubber, wired on, is recommended in preference to metallic pipe for connections between recorder and individual boiler flues. Glass stopcocks, soot filters, and water-jet pumps are discussed.

A. G. BLAKELEY.

**The chemical and physical control of boiler operation.** E. A. UEHLING. *J. Am. Soc. Mech. Eng.* 41, 137-41, 199(1919).—The author shows by actual example certain calcns. which may be made from data given by recording-instrument charts, with a view to increasing the efficiency of power plants. Formulas and tables of results accompany the discussion.

F. W. SMITHER.

**Coal economics.** G. BASTIEN. *l'Industrie chimique* 5, 313-5(1918).—A review and discussion of a paper by Brownlie, *et al.* (*C. A.* 13, 255; cf. also *C. A.* 13, 66).

F. W. SMITHER.

**A fusion bomb for sulfur determination in coal.** S. W. PARR. *J. Ind. Eng. Chem.* 11, 230-1(1919); illus.—The app. is adapted for use in S detn. in coal by use of Na<sub>2</sub>O<sub>2</sub>. It has also been used satisfactorily in the detn. of S in pyritic material, in rubber and in other org. combinations. It has still wider application in the detn. of carbonaceous matter in soils, and as a substitute for the Carius method of detg. halogens in org. compds.

E. J. C.

**Estimation of sulfur in spent oxide.** WM. DIAMOND. *J. Soc. Chem. Ind.* 37, 336-71(1918); *Gas J.* 145, 24(1919).—The S in spent oxide is usually estd. by extn. with CS<sub>2</sub>. But the results are often misleading due to the presence of other impurities, such as CN compds., NH<sub>3</sub>, tar and oil, extd. by the CS<sub>2</sub> and weighed as S. According to Mendelyev, S is sol. in CS<sub>2</sub> in practically all proportions, but is only slightly sol. in cold benzene. By washing dry spent oxide with several portions of benzene, all the tar and oil will be extd., leaving only the S to be extd. with CS<sub>2</sub>. About 10 g. of the oxide is placed in an extn. thimble and 9 successive portions of 20 cc. of cold benzene are poured over the sample, each portion being allowed to filter through the oxide before another portion is added. The whole ext. is divided into 2 parts: the first is evapd. to dryness and the residue weighed, the second is evapd. to dryness, boiled down with HNO<sub>3</sub>, H<sub>2</sub>O is added, and the S pptd. by BaCl<sub>2</sub> and weighed as BaSO<sub>4</sub>. The first estn. gives total tar, oil and sol. S compds., the second represents S only. The S is then extd. from the same sample with CS<sub>2</sub> in a Soxhlet extn. app. as usual. The weighings will give (1) tar, oil and organic matter sol. in benzene, (2) S compds. sol. in benzene, (3) S extd. by CS<sub>2</sub>. In one test extn. with benzene gave residues of 14.18 and 13.37% in duplicate tests; the amts. of S found by weighing as BaSO<sub>4</sub> were 9.17 and 8.22%; thus the % of tar and other sol. matter were 5.01 and 5.14%, av. 5.07%. The amts. extd. by CS<sub>2</sub> from the original oxide were 49.87 and 49.79%, av. 49.83%. so that the actual S content of the sample was 44.76%.

J. L. WILEY.

**Relation between molecular structure and the activity towards hydrogen sulfide of oxide of iron.** G. WEYMAN. *J. Soc. Chem. Ind.* 37, 333-61(1918).—The sulfides of Fe with which gas purification is concerned are Fe<sub>3</sub>S<sub>4</sub>, which is oxidized to free S and Fe<sub>2</sub>O<sub>3</sub>; FeS, which is also oxidized to free S and Fe<sub>2</sub>O<sub>3</sub>, and which at higher temps. may combine with free S to form FeS<sub>2</sub>. Purification of coal gas is carried on at temps. somewhat above the normal under which conditions Fe<sub>3</sub>S<sub>4</sub> is the chief product. It has been previously found (*J. Soc. Chem. Ind.* 1883, 156) that by treating the hydrate pptd.

by  $\text{NH}_3$  from  $\text{FeCl}_3$  with  $\text{H}_2\text{S}$  and treating the product with  $\text{CS}_2$  out of contact with air, there was obtained a variable amt. of free S which bore no relation to the total quantity of free S obtained after oxidation. Free S is always present and  $\text{FeS}_2$  is produced by local heating. Subsequent oxidation might account for part of the  $\text{FeSO}_4$  found. This reaction always results in the liberation of  $\text{SO}_3$ . To be efficient the oxide must be kept in an alk. condition, in which case the  $\text{FeSO}_4$  formed is at once decompd. with liberation of  $\text{Fe(OH)}_3$ . Even in an alk. condition the activity of the oxide falls off in time. In an acid condition the amt. of Fe rendered inert by formation of ferric and ferrous salts or as  $\text{FeS}_2$  is not sufficient to account for the almost complete inactivity of the whole body of the oxide. From expts. carried out to det. the temp. at which hydrated oxide becomes inactive, it is evident that  $\text{Fe(OH)}_3$  dehydrated at as high a temp. as  $650^\circ$  may still retain its activity in the cold. At about  $700^\circ$  a change sets in which may also be effected at lower temps. by very prolonged heating. Under certain conditions and with particular varieties of oxide, the absorption of  $\text{H}_2\text{S}$  may take place in the comparative absence of  $\text{H}_2\text{O}$ . In all cases but one the oxide obtained after heating to from  $100^\circ$  to  $650^\circ$  gave in the cold practically theoretical absorption calcd. on the content of  $\text{Fe}_2\text{O}_3$ . Oxide heated to  $700^\circ$  gave only a partial absorption, the extent of which depended on the time of heating, and ranged from 10–32% of the  $\text{H}_2\text{S}$ . Oxide heated to  $800^\circ$  absorbed less than 1%. In all cases most of the water of hydration was given off before  $300^\circ$ . Even the oxide heated to  $800^\circ$ , which was inactive in the cold, absorbed the gas rapidly at the higher temp. This indicates that the change in structure which inhibits the action of  $\text{H}_2\text{S}$  in the cold must take place on cooling, and that at  $800^\circ$  the oxide mols. are in such a mobile state that slow cooling gives them an opportunity of arranging themselves in a more condensed state. To obtain further evidence of this some oxide was heated for 3 hrs. to  $800^\circ$  and all but a check portion was plunged suddenly into cold water. The check sample which was cooled slowly absorbed less than 1% of  $\text{H}_2\text{S}$  in the cold, while after drying the quickly cooled sample absorbed 43%. The sp. grs. of the powders obtained by heating to various temps. and cooling slowly showed a progressive rise: at  $300^\circ$  sp. gr. = 4.207,  $510^\circ$  = 4.444,  $700^\circ$  = 4.485. "Burnt oxide" from the manuf. of  $\text{H}_2\text{SO}_4$  and sometimes used for gas purification, is in a similar condition to the oxide heated above  $700^\circ$ . It is then concluded that the chem. activity of  $\text{Fe}_2\text{O}_3$  is dependent primarily on mol. structure, and not on any particular degree of hydration. At the same time the mol. structure is evidently derived from some form of hydrate. W. reviews the work of former investigators on the constitution of ferric hydrates and shows how their conclusions are confirmed in the study of gas purification.

J. L. WILBY.

**Soft coal for water gas.** ROBERT B. HARPER. Peoples' Gas, Light & Coke Co., Chicago. *Gas Record* 14, 257–64(1918); *Gas J.* 145, 121(1919).—A detailed analysis of factors affecting the use of bituminous coal in water-gas generator is given. A change in the compn. of the generator fuel from that of a good coke to that of a bituminous coal may result as follows: (1) In the increase of clinker or ash to be removed thus increasing the cleaning time and reducing the gas made per day by as much as 5%. (2) In the production of lumpy or coarse ash presenting less surface for chem. action, affecting the compn. and hence the fusion point and physical condition of the resulting clinker. (3) In the liberation of considerable volatile matter from the coal, which being driven off during the blast causes more or less smoke at the open stack valve. (4) In the increase of the heating value and perhaps also of the sensible heat of the producer gas, tending to result in overheating of the checkerbrick in the carburetor and superheater. (5) A decrease of perhaps 40% in the output of blue water-gas and 35% of crude carbureted water-gas. (6) An increase of the time of contact of the oil vapors and gases with the blue water-gas and the brick surface in the car-

buretor and superheater due to the decrease in the rate of output of blue water-gas from the generator resulting in a more extensive cracking and less efficient decompn. of the oil at the same checkerbrick temp. used in the case where the generator fuel is coke. (7) A change in the compn. of the blue water-gas by the liberation of some volatile matter so that the heating value tends to be increased as much as 40 B. t. u. per cu. ft., thus making a slight oil saving in the manuf. of carbureted water-gas. (8) In the possibly detrimental effect of the compn. of the blue water-gas upon the compn. of the crude oil-gas produced and the tendency to increase the deposition of C on the checkerbrick and the amt. of tar formed. (9) In the formation of more  $H_2S$  due to an increase in the % of total S in the fuel charged, resulting in overloading the purifying equipment. (10) In the variation of the free space for gases in the generator fuel due to the tendency of bituminous coal to form "channels" in the fuel bed or a packed condition of the fuel, both conditions being detrimental to good results. (11) In maintaining a shallower fuel bed in order to permit primary or main blast air to pass more readily through the fire. (12) In the possible tendency of the ash of some coals under certain blast conditions to blow over from the generator and form deposits on the checkerbrick, thus rendering the efficient decompn. of the gas oil less likely. (13) In the formation with some coals of a clinker or ash of such a nature as to cause a loss of practically unrecoverable C amounting to as much as 3% of the fuel charged. (14) In the increase in the amt. of steam used per M cu. ft. of gas in order to keep the physical conditions of the clinker such as to permit its easy removal. (15) In the probable lowering of the temp. of the fuel surface, because of the smaller amt. of surface and more compact nature of bituminous coal, tending to increase the excess steam leaving the generator, thus having a somewhat detrimental effect upon the gas oil compn. (16) In the securing of some economies in the manuf. of carbureted water-gas in case the difference in costs of coke and coal is sufficiently large and other conditions permit advantage being taken of such possible economies. (17) In the impossibility of manufg. enough carbureted water-gas with bituminous coal to meet the requirements of customers of a gas company whose max. possible gas machine capacity with good coke is only sufficient to meet such requirements.

J. L. WILEY.

**Steaming horizontal retorts.** R. J. R&W. *Gas J.* 145, 69-70(1919); *Gas World* 70, 35-6(1919); cf. *C. A.* 12, 1697.—It has been thought that the horizontal retort is unsuitable for water-gas production, but R. shows that when the work is carried out in a scientific way good results are realizable, although not so good as are possible with vertical retorts. The conditions inside the retorts are altogether unlike and therefore the methods must be varied. In regard to steaming, horizontal retorts clearly have limitations, but nevertheless steaming can be made a paying proposition both in the increased production of gas and in the saving of fuel and labor. Instead of the usual production of 11,300 cu. ft. of gas, R. obtains now an av. of about 14,200 cu. ft., meanwhile saving 20.4% of coal. At the end of an 8-hr. carbonizing period, a couple of retorts in a bed of sixes or eights are set off and the spent charges are steamed for 40 hrs. It is preferable that the 2 retorts be of special construction, and such a retort is the subject of a patent. Superheated steam is essential, and great care must be taken not to overdo the steaming. Max. time-contact is necessary, which means low steam pressure and speed. The reason the steam cannot be continuously applied during the whole carbonizing period as in continuous vertical retorts is that, with a comparatively shallow depth of semi-carbonized coal, or partially incandescent coke, the production of  $CO_2$  would be enormously increased. But, providing the app. and methods are correct, during the 40-hr. steaming period, good water gas is produced from the 2 retorts and also at the same rate per retort as when making coal gas. The amt. of  $CO_2$  is kept within a 5% av. This is higher than the av. with continuous vertical retorts,

but is not a matter of great importance. A disadvantage is that the hydrocarbons are not accelerated and protected from degradation in their departure from the retorts, nor is there the additional H to pick up some of the residual volatile matter from the coke. No figures are given as to the calorific value or analyses of the mixed gas. 140 gas companies have decided to give the process a trial, which speaks well for the possibilities of the method.

J. L. WILEY.

**The use of peat in steam generators and in gas producers.** L. F. *Rev. chim. ind.* 27, 188-91(1918).—When peat is employed for the heating of boilers, the grate-bar spacing is less than that required for coal. The distance between grate-bars depends upon the grade of peat used and varies between 8 and 20 mm. The av. height of the bed of peat above the grate varies between 75 and 250 mm. In Sweden 1 kg. of peat has evapd., in a tubular boiler, 4.32 kg. of vapor at 6.7 atms. pressure, whereas with coal, 7.44 kg. of vapor are obtained under the same conditions. In other words, one unit of coal is equiv. to 1.72 units of peat. Locomotives require about twice as much peat as coal, by weight, and two firemen are required when peat is used. Inclined grates have been designed to handle peat and may be made automatic. The use of peat in the so-called semi-gas producers has been generally successful and special app. has been designed to burn powdered peat. There are several types of producers designed to handle peat among which are: the G. Korting, G. Luther and Ziegler, which are in use in Germany and Sweden, the Mond, and Limm in use in England and Italy, and the Riché and Allégre et Fabre, used in France. Several details of these types are given.

J. H. YOUNG.

**Unusual carbonizing methods.** JAMES A. BROWN. *Gas J.* 145, 28(1919).—A paper read before the Michigan Gas Association descriptive of inclined oven plants at Flint, Mich., and Evansville, Ind., and horizontal oven plants at Jackson, Pontiac, and Kalamazoo, Mich. Some difficulties in design and operation of plants and remedies therefor are given. Mechanically operated plants handling large charges and horizontal ovens for capacities above 500,000 cu. ft. are recommended. J. L. WILEY.

**Ammonia plant at the Stockholm gas works.** ANON. *Gas Age* 43, 132-4, 183-5 (1919); illus.—A detailed description of modern aqua-NH<sub>3</sub> and (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> plants of latest Swedish design operating under the indirect process. The latter has a capacity for treating 210 cu. ft. of 2% ammoniacal liquor in 24 hrs., the former 1750 cu. ft. NH<sub>3</sub> in 24 hrs.

J. L. W.

**Analyses of commercial "pure" benzene.** F. BUTLER JONES. *J. Soc. Chem. Ind.* 37, 324-71(1918).—A new method for the detn. of small quantities of thiophene, toluene, CS<sub>2</sub> and paraffin, in benzene in absence of other compds. is described. The method is based upon the fact that the depression of the f. p. of solns. of up to 4% of thiophene, CS<sub>2</sub>, toluene and paraffin in benzene is nearly proportional to the wt. per cent. of solute present. The measurements required are three f. ps. and one sp. gr. The first freezing-point detn. is taken on the soln. containing all 4 compds., after which the CS<sub>2</sub> is removed by means of alc. potash. The second f. p. is taken of the soln. freed from CS<sub>2</sub>. Thiophene is then removed by shaking with a cold soln. of basic mercuric sulfate and a 3rd f. p. is detd. The sp. gr. of this last soln. is also taken. By making use of curves which are given, the f. p. information and the sp. gr. figure may be translated into the percentage of each of the components in the system. The method is applicable to commercially "pure" benzene.

J. H. YOUNG.

**Determination of the water content in tar.** W. SPALTEHOLZ. Amsterdam. *Chem. Weekblad* 15, 1546-8(1918).—An iron kettle containing 1½ l. is used to det. the H<sub>2</sub>O in tar. It has a side outlet near the top, and 4 openings in the cover, one for a thermometer, one connected with the side outlet, one for a condenser, and one bearing a dropping funnel. The funnel discharges into a small cylindrical reservoir which

overflows into the kettle. To make the detn., fill the kettle with anhydrous high boiling anthracene oil, heat to  $270^{\circ}$  and let the tar sample drip slowly into the hot oil from the funnel. The high boiling part escapes through the side outlet, the  $H_2O$  through the condenser. The app. requires no refilling after a detn., and permits rapid and sufficiently accurate work. Also in *Het Gas* 38, 302-4(1918). JULIAN F. SMITH.

Tentative specifications for coal-tar pitch for use in damp-proofing and waterproofing. ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 635-8(1918).—Tentative specifications covering coal-tar pitch for use in waterproofing and damp-proofing, recommended for use under uniformly moderate temp. conditions. J. H. YOUNG.

Solubilities, separation and purification of anthracene, carbazole and phenanthrene (CLARK) 10. Coal in southeastern Idaho and western Wyoming (SCHULTZ) 8. Sulfuric acid plants ("P") 18.

Artificial fuel. T. TWYNAM. *Brit.* 121,373, Dec. 29, 1917. Wet or air-dried peat is intimately mixed with dry pitch and coke dust or small coal, or with coke dust and small coal, the whole being ground together. The product may be molded into blocks for use as fuel or for use in coke ovens. The coke dust and dry pitch may be mixed in the proportion of 3 to 2, and 100 parts of wet peat and 15 parts of the mixt. may be ground together.

Coal gas. W. D. WILCOX. U. S. 1,289,336, Dec. 31. Coal containing a high % of moisture is passed continuously downwardly through an externally heated retort. A distn. at relatively low temp. takes place in the upper portion of the retort and gaseous products are withdrawn from an outlet in the upper portion of the retort. A distn. at relatively high temp. takes place in the lower portion of the retort and gases are also withdrawn from the lower portion. The residue from the retort is fed into a generator chamber below and connected with the retort and the material in the generator chamber is alternately treated with air and with the gaseous products from the low-temp. distn. Several retorts are operated simultaneously and the operations in them are so conducted that the low-temp. gases may always be passed directly as formed into residue in one of the generator chambers. Gaseous products from the passage of air through the residue in the generator chamber are led to a common heating chamber supplying the flues which surround and heat the retorts and are burned therein. Gases from the passage of gases of low-temp. distn. through the residue are led through the lower portion of the connected retort to the lower outlet therefrom.

Removing water from peat. A. TEN BOSCH. U. S. 1,290,494, Jan. 7; Can. 188,789, Feb. 18, 1919. Peat from which  $H_2O$  is to be removed is forced in the form of a pulp, in a continuous stream, through a vertical pipe in which the weight of the column of peat exerts considerable pressure upon its lower portion and steam under pressure is forced into the lower part of the column.  $H_2O$  is forced out under pressure.

## 22. PETROLEUM, ASPHALT AND WOOD PRODUCTS.

F. M. ROGERS.

Commercial possibilities of oil shale. H. J. WOLF. *Eng. Mining J.* 107, 217-9 (1919).—A review of current possibilities of oil shale, with a description (with illustrations) of the Utah and Colorado oil-shale deposits and details of the present state of their development. F. W. SMITHER.

Borings for oil in the United Kingdom. V. C. ILLING. *Nature* 102, 385-8(1919).—The possibility of finding commercial quantities of oil in the drillings that are now being made in selected areas in Great Britain is discussed from a geological point of

view and the evidence is thought to warrant the conclusion that large commercial underground supplies of petroleum do not exist in the country. W. H. ROSS.

**Report of committee D-2 on lubricants.** ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 321-2(1918).—The committee recommends the adoption as standard of the tests presented last yr. (cf. *Proc. Am. Soc. Testing Materials* 17, Pt. I, 767(1917)) with the addition of the stipulation that in detg. d. "correction for the buoyant effect of the atm. shall be made when necessary." The tests included: cloud and pour test for petroleum oils except steam cylinder and black oils; cold test for steam cylinder and black oils; free acid; C residue. It is also recommended that "standard temps. for viscosities" contained in the last report be withdrawn. F. W. SMITHER.

**Internal-combustion engine: lubrication and lubricants.** P. H. CONRADSON. *Proc. Am. Soc. Testing Materials* 18, Pt. II, 387-92(1918).—See C. A. 12, 2247.

F. W. SMITHER.

**The formation of a precipitate in lubricating oils during use.** H. I. WATERMAN. Dordrecht. *Chem. Weekblad* 15, 1610-1(1918).—A sample of used lubricating oil settled in 3 layers, the bottom being clear water, the middle an opaque ppt. and the upper layer clear brownish oil. The ppt. was only an emulsion of the oil with pure water, evidently the condensate from the machine in which the oil had been used. Analyses of fresh samples showed that the oil itself was of mineral origin and of good quality. JULIAN F. SMITH.

**Tentative specifications for asphalt for use in damp-proofing and water-proofing.** ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 630-3(1918).—The specifications cover asphalt for use in damp-proofing and water-proofing, recommended for use under uniformly moderate temp. conditions. J. H. YOUNG.

**Tentative specifications for primer for use with asphalt for use in damp-proofing and water-proofing.** ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 634(1918).—The specifications cover primer for use, when specified, with asphalt for use in damp-proofing and water-proofing. J. H. YOUNG.

**Tentative methods for determination of softening point of bituminous materials other than tar products.** ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 707-8 (1918).—Tentative method for detn. of softening point of bituminous materials other than tar products as issued in 1916. J. H. YOUNG.

**Tentative specifications for creosote oil for priming coat with coal-tar pitch for use in damp-proofing and water-proofing.** ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 639-40(1918).—The specifications cover primer for use under coal-tar pitch, when specified. J. H. YOUNG.

---

**The recovery of waste paraffined paper (KRESS, HAWLEY) 23.** Oil-filtering apparatus (U. S. pat. 1,290,820) 1.

---

GUTTENTAG, WILFRED E.: **Petrol and Petroleum Spirits: A Description of their Sources, Preparation, Examination and Uses.** New York: Longmans, Green & Co. 135 pp. \$3.40.

---

**Cracking oils.** C. ELLIS, N. L. FOSTER and ELLIS-FOSTER Co. Brit. 121,356, Dec. 15, 1917. Heavy petroleum oils are treated for the production of gasoline, etc., by passing their vapors through a zone of progressively increasing temp., and then subjecting the cracked products to a progressively decreasing temp. until the secondary reactions due to the unsatd. nature of the products of the cracking operation have attained a stage of equil. A suitable app. is specified.

**Acid-coke as fuel.** G. L. PRICHARD. U. S. 1,290,345, Jan. 7. A fuel suitable for burning in fuel-oil burners is formed by mixing heated oil with acid coke from sludge acid, obtained in petroleum refining.

**Hydrocarbon extraction from shale.** V. Z. REED. Can. 188,464, Jan. 28, 1919. The shale or coal containing the desired hydrocarbon is treated with hot vaporous material containing acid, the vapors condense in the shale and in passing downward therethrough exercise a solvent action on the oil material; the solvent and extd. matter are recovered and distd.

**Breaking up emulsions of oil and water.** F. M. SEIBERT and J. D. BRADY. U. S. 1,290,369, Jan. 7. Emulsified oil and  $H_2O$  are sepd. by passing the liquid in a flowing stream between a pair of electrodes between which a potential of 250-600 volts is maintained, spaced sufficiently far apart to prevent passage of any substantial amount of current. The electrodes may be of tubular form and concentrically placed.

### 23. CELLULOSE AND PAPER.

A. D. LITTLE.

Report on the resources and economic needs of France in the post-bellum period, and on the changes to be made in the tariff protecting the paper industry. *Le papier* 21, 188(1918).—The French paper industry demands that a special duty be placed on all wood exported from allied countries to the Central States, and on all pulp imported by Allied countries from the Central States, and also that the tariff be raised on chemical pulp imported into France, but not on mechanical pulp. A. PAPINEAU-COUTURE.

Report of the National Paper Bureau on the needs of the French paper industry during the first five years after peace is declared. *Le papier* 21, 185(1918).—France will need to import annually at least 850,000 steres of wood (1 stere = 35.31 cu. ft.), between 40 and 50,000 tons of waste paper, 100 to 150,000 tons of alfa, 200,000 tons of mechanical pulp, 250,000 tons of chem. pulp, 70,000 tons of kaolin. It can supply its own needs for cotton and woolen rags, and straw. 60,000 to 70,000 h. p. would suffice to manuf. all the mechanical pulp imported and 25,000 h. p. for the chem. pulp imported. The industry can supply all domestic requirements, but there will probably be little or no exportation for some time, with the possible exception of the very highest grade papers. A. P.-C.

The Russian paper industry. Notes on the developments of papermaking in Russia since the XVIth century. Report presented in 1916 to the Paper Committee in Petrograd. G. R. SAEELMANN. *Le papier* 21, 197(1918). A. P.-C.

The art of determining the composition of papers. E. ARNOULD. *Le papier* 21, 161(1918).—This paper does not deal with methods but discusses the qualifications which the paper-mill superintendent should have relative to this art.

A. PAPINEAU-COUTURE.

The recovery of waste paraffined paper by extraction with volatile solvents. OTTO KRESS and L. F. HAWLEY. *J. Ind. Eng. Chem.* 11, 227-9(1919).—Waste paraffined paper was extd. with gasoline in a small intermittent extractor, the amt. of solvent and paper being varied in different runs. Two extns. were made on each charge of paper, the amt. of solvent used in the second extn. being equal to the amt. drained off from the first. Using 20 gals. of gasoline (b. 90-140°) at one application per 7 lbs. of paper, the paraffin retained by the paper amounted to 0.21%, based on the extd. paper. Using 8 gals. of gasoline per 20 lbs. of paper, the paraffin retained was 3.40%. With a large well designed extn. system, it should be possible to get even better results with less solvent. R. B. ROG.

**Tropical grasses as paper-making materials.** ANON. *Bull. Imp. Inst.* 16, 3, 271-5(1918).—*Lalang grass* (*Imperata arundinacea*) covers large areas in the states in the Malay peninsula and is considered a troublesome weed. A sample showed 9.2% moisture, and ash 4%, cellulose 50% (these last being calcd. on the dry material). The grass when treated with from 8 to 20% NaOH soln. yielded from 46 to 40% of dry pulp. The pulp did not bleach readily but possessed good filling qualities and produced a strong opaque paper. A specimen of *bamboo grass* from Northern Australia was also examd. This material showed 9.9% moisture, and 12.2% ash (expressed on dry grass) and 48.9% cellulose. The grass, when boiled for 5 hrs. at 140° with 16 to 20% NaOH, yielded 43 and 39% dry pulp. It was found that the quality of the pulp could be improved if the nodes of the grass were crushed first. The pulp was bleached and gave a paper of fair quality.

R. L. SIBLEY.

**Cardboard containers for canning.** *Bull. Australian Sci. Soc.; Le papier* 21, 210(1918).—Cardboard containers are coated with a MeOH soln. of a special resin, obtained by action of CO<sub>2</sub> and HCHO, thereby preserving the contents from decompn.

A. P.-C.

**Adhesive from waste sulfite liquor.** W. H. DICKERSON. U. S. 1,290,118, Jan. 7. An adhesive suitable for use in road building, making sand cores, and for other purposes, is produced by concg. waste sulfite liquor *in vacuo*, and, during the concn., adding CaCO<sub>3</sub> in somewhat less amt. than that which would be required for complete neutralization of the acid in the liquor.

**Waterproof paper.** J. T. CROLL. *Brit.* 121,318, Dec. 4, 1917. In the manuf. of waterproof paper, the paper is passed directly from the delivery end of a paper-making machine through a bath of wax or other waterproofing material, then guided through rolls to and in a drying chamber, and there subjected to the action of fans or pressure air.

## 24. EXPLOSIVES AND EXPLOSIONS.

CHARLES E. MUNROE.

**Old and new explosives.** D. H. WESTER. *Artill. tijdschr.* 1918, 26 pp.; *Chem. Weekblad* 15, 1364-5.—A résumé of a series of lectures. Although some progress has been made in recent years, the ideal explosive (hexanitrobenzene) is yet to be prepd.

JULIAN F. SMITH.

**Studies of modern brisant explosives.** C. F. VAN DUIN. Thesis, Utrecht 1918, 113 pp.; *Chem. Weekblad* 15, 1521-3.—The work of previous investigators on explosives is reviewed. Methods of prepn. are given for many explosives, some of which are of only theoretical interest. In a study of the constitution of 2,4,6,2',3',4'-hexanitrodiphenylamine, in which only the positions 2, 4, 6 and 3' were previously known to be correct, it was shown that the 5th NO<sub>2</sub> group is in the position 4'. Evidence, but not proof, was found that the 6th is in the position 2'. In a study of tetranitrophenylmethylnitramines, it was shown that the mobility of the methylnitramine group is increased by the introduction of a positive substituent in the meta position, and decreased by a negative group in the meta position. The introduction of a mobile NO<sub>2</sub> group or a 2nd methylnitramino group in such compds. greatly increases the sensitivity to shock.

JULIAN F. SMITH.

**Quantitative determination of acetone in smokeless powder.** A. PIERONI. *Atti r. accad. Lincei* 27, II, 52-7(1918); *J. Soc. Chem. Ind.* 37, 749A.—Discordant results obtained in the detn. of Me<sub>2</sub>CO are due to the difficulty of converting Me<sub>2</sub>CO quant. into CHI<sub>3</sub>, to the ease with which the latter is attacked by excess of alkali, to the loss

of I owing to secondary reactions, and to the volatility of  $\text{CHI}_3$ . The following procedure gives satisfactory results with smokeless powders which contain between 3 and 0.25% of  $\text{Me}_3\text{CO}$ : From 35 to 50 g. of the powder in lumps is weighed to the nearest 0.01 g. and ground in a special app. in which the powder is kept washed by a stream of distd.  $\text{H}_2\text{O}$  so as to prevent evapn. of the solvent. The ground mass, together with the  $\text{H}_2\text{O}$ , is either collected in a large beaker or passed directly through a funnel into a distn. flask of about 2 l. capacity; 100 cc. of dil.  $\text{H}_2\text{SO}_4$  (1:1) is then added to prevent emulsification of the distillate. Steam is passed into the flask, which is also heated with a burner. The distillate passes from the condenser into a bulb'd adapter reaching almost to the bottom of a test tube full of water in a conical flask. From the latter unabsorbed gases pass through a washer, which retains any traces of  $\text{Me}_3\text{CO}$  still unabsorbed. When 250–300 cc. of distillate, *i. e.*, rather more than one-half of the vol. of liquid originally in the distg. flask, has been collected, the adapter is removed and a little fresh distillate is collected in a test tube and tested for  $\text{Me}_3\text{CO}$  by means of KOH and I. When  $\text{Me}_3\text{CO}$  ceases to distil over, the whole of the liquid in the collecting flasks, together with the washings of these and of the adapter, is made up to 500 cc. in a measuring flask. Exactly 100 cc. of the mixed soln. is pipet'd into a cylinder of about 300 cc. capacity with a ground stopper. From two burets are then run in a soln. containing 112 g. of KOH per l. and another containing 257 g. of I and 330 g. of KI per l.; the two solns. should drop at the same time and at the rate of about 20 drops per min., the cylinder being kept shaken meanwhile. From time to time the addition is stopped for a time until the  $\text{CHI}_3$  settles and the supernatant yellow liquid clarifies; if further addition of the KOH and I solns. produces no turbidity, the transformation of the  $\text{Me}_3\text{CO}$  is complete. After a rest of a few mins., such excess of NaCl is added that 10 g. or so remains undissolved, 50 cc. of  $\text{Et}_2\text{O}$  kept over Na is added, the cylinder tightly closed and the liquid shaken energetically three or four times. As soon as the two layers have sepd. completely, 25 cc. of the ethereal  $\text{CHI}_3$  soln. is pipet'd into 25 cc. of satd. alc. KOH soln.; the vol. of alc. KOH to be used varies with the vol. of I used in the reaction with the  $\text{Me}_3\text{CO}$ , the former being in general double the latter. The liquid is dild. with EtOH until clear, heated in a water bath to evap. the  $\text{Et}_2\text{O}$ , and boiled for 15 min.; the EtOH is then distd. off, the liquid dild. with  $\text{H}_2\text{O}$ , cooled, and acidified with dil.  $\text{HNO}_3$ , and the KI formed detd. volumetrically by Volhard's method. If *a* is the number of cc. of 0.1 *N*  $\text{AgNO}_3$  soln. used and *b* the weight in g. of the powder taken, the percentage of  $\text{Me}_3\text{CO}$  in the latter will be  $2a/b$ . CHARLES E. MUNROE.

**Analysis of detonator compositions.** MARQUEYROL AND P. LORLETTE. *Bull. soc. chim.* 23, 401–3 (1918).—A rapid method for the detection and approx. detn. of the components of detonator charges, some of which may be present in but small quantities. (1) Digest with anhydrous  $\text{Et}_2\text{O}$  which dissolves such substances as T. N. T., picric acid and tetryl. Filter, wash insol. residue with  $\text{Et}_2\text{O}$ , evap. the filtrate on tared crystal, dry at  $60^\circ$ , weigh, and then identify by the reactions characteristic of the several nitro-substitution compds. (2) Digest the residue from above in a few cm. of cold  $\text{H}_2\text{O}$ . Filter, wash with a very little cold  $\text{H}_2\text{O}$ , evap. the filtrate at  $60^\circ$  on tared crystal and weigh. Then exam. this mass for chlorates, nitrates, etc. (3) Treat the second insol. residue above with 10 cm. of a cold 5% soln. of KCN, digest for 2 hrs. with occasional shaking, filter, wash with a few cm. of the KCN soln. and then  $\text{H}_2\text{O}$ . Electrolyze the filtrate in a crucible with a Riche app. of 2 accumulator elements, weigh the Hg and calc. the  $\text{Hg}(\text{ONC})_2$ . Or decompose the KCN soln. with  $\text{HNO}_3$ , when practically all the  $\text{Hg}(\text{ONC})_2$  will sep. out. (4) Place the residue insol. in KCN soln. in a small distg. flask with a few cc. of  $\text{H}_2\text{O}$  acidify with 1 cm. of glacial AcOH, heat to boiling and filter into a 5% soln. of  $\text{AgNO}_3$ . When  $\text{PbN}_3$  is present  $\text{AgN}_3$  is pptd. This is collected, washed with a little  $\text{H}_2\text{O}$ , then EtOH and  $\text{Et}_2\text{O}$ , dried, weighed and

the  $\text{PbN}_3$ , calcd. from it. The  $\text{AgN}_3$  is identified by its behavior under blows and in flames. Examples of results are given. Cf. *C. A.* 12, 628, 995, 2440. C. E. M.

**Trinitrotoluene residues and their utilization.** MAURICE COPISAROW. *Chem. News* 118, 13-4(1919).—Residues are derived from (1) spent nitration acids and (2) processes of purification by recrystn. or washing. Dissolved T. N. T. is recovered from spent acids by dilg. the latter. Extended diln. is inadvisable since by no extent of diln. will all the dissolved nitro compds. be pptd., and it renders the recovery of the acids uneconomical. C. advises diln. of acids just enough for sepn. and convenient removal of the bulk of nitro compd. and then extg. acids with  $\text{C}_7\text{H}_8$ , which gives a fairly concd. acid practically free from nitro compds. and a  $\text{C}_7\text{H}_8$ , ext. that may be transferred to the nitrators. Among several methods for the purification of T. N. T. that of employing EtOH as a solvent and crystg. medium or as a washing agent occupies an important position. The latter method yielding a somewhat inferior product presents a considerable technical advantage and its product meets all ordinary requirements. On the removal of the EtOH from the mother liquor or the washings a dark brown, thick liquid was obtained. This was purified by soln. in  $\text{C}_6\text{H}_6$  in which all but 1.35-1.40% was sol. The purified  $\text{C}_6\text{H}_6$ -free substance was found to contain dinitrotoluenes 82.26-80.32% and trinitrotoluenes 17.74-19.68%. On long standing at ordinary temp. the residue gradually crystallizes to a semi-solid mass which centrifuges to (a) a brown solid containing 1.45-1.55% insol. in  $\text{C}_6\text{H}_6$  and (b) a liquid resembling the original residue. The proportion of solid matter so obtained to the total varies appreciably, depending upon the conditions of the alc. treatment and the duration and range of cooling, but it is seldom below 18%. C. nitrated the crude residue with mixed acids ( $\text{HNO}_3$  15-17%,  $\text{H}_2\text{O}$  6%) at 100-120°, obtaining 48.4-64.5% of liquid T. N. T., containing 16.9-17.4% N, which gelatinized gun cotton and was well suited for manuf. of gelatin dynamite. By nitrating this liquid "T. N. T." or the original residue with mixed acids ( $\text{HNO}_3$  17%,  $\text{H}_2\text{O}$  4%) at 120°, a slightly yellowish solid, resembling good quality crude T. N. T., is obtained having a setting point of 57-58° and containing at least 98% T. N. T. This must be regarded as a mixt. of T. N. T. isomers. As  $\alpha$ -T. N. T. forms addition compds. with hydrocarbons, phenol, amines and nitro compds., such as mono- and dinitrotoluenes, Lepsius suggests the possibility that the product consists of a mixt. of addition compds. rather than a mixt. of free isomers. Since according to Will the  $\alpha$ -,  $\beta$ - and  $\gamma$ -trinitrotoluenes, and probably all other modifications, are of practically the same value as explosives, this low melting explosive is useful as a constituent of bellite, roburite and similar blasting explosives, and for war uses where a lowering of the m. p. is required as in the case of the trinitroxylenes. C. styles this material *Iso-Trotyl*. When these T. N. T. residues are treated with bleaching powder  $\text{CCl}_3\text{NO}_2$  is produced, the yield comparing favorably with that obtained from  $\text{HOC}_6\text{H}_4\text{NO}_2$  residues. When these T. N. T. residues are fused with  $\text{Na}_2\text{S}$ , with or without S, dyes are obtained which dye unmordanted cotton fast colors, varying from gray to khaki and brown, the color depending on the concn. of the bath, the temp. and duration of the fusion, and the addition of S.

CHARLES E. MUNROE.

**Fatal cases of poisoning by trinitrotoluene and tetranitromethane.** FISCHER. *Zentr. Gewerbehyg.* 1917, 205; *Chem.-Ztg.* 1918, 42, Rep. 165; *J. Soc. Chem. Ind.* 37, 750A.—The history of 7 fatal cases of poisoning by T. N. T. is described; F. expresses the opinion that the actual cause of the poisoning was the  $\text{C}(\text{NO}_2)_4$  present, in greater or smaller quantity. Evidence in favor of this view is brought forward. C. E. M.

**Spontaneous explosion of the charcoal in liquid-oxygen containers.** LOTHAR WÖHLER. *Chem.-Ztg.* Oct. 5, 1918; *Engineering* 106, 687.—Several cases of explosion of liquid-O containers occurred, all of the vessels having been supplied by one Austrian firm. These vessels, like those of other mfrs., were made of metal, double-walled, with

the jacket-space filled with charcoal to maintain a vacuum. Explosions occurred when the inner wall of the Austrian vessels were so broken that the O had access to the charcoal but did not occur when the vessels of other mfrs. were broken in the same manner. It was found that the charcoal in the faulty vessels contained Zn and Fe and that 3.5% of the latter, in the form of oxide, in the charcoal caused an explosion on contact with O, while 2-3% gave rise to a violent reaction, but less than 2 produced no deleterious effect. The Fe oxide appears to act catalytically as an O carrier, and 0.1 g. of the highly porous charcoal containing the designated amt. of Fe oxide proved sufficient to cause an explosion. W. states that explosions of blasting cartridges containing soot or sawdust and liquid O have occurred during the charging of bore holes due to the liquid O gaining access to combustible material which had been heated by the process of tamping.

CHARLES E. MUNROE.

Course of reaction in explosions of dilute carbon disulfide-air mixtures. G. R. STEWART AND JOHN S. BURD. *J. Ind. Eng. Chem.* 11, 130-3 (1919).—CS<sub>2</sub> is used for destroying burrowing rodents by pumping the vaporized CS<sub>2</sub> into the burrows or by inserting a cloth satd. with the liquid CS<sub>2</sub> and igniting it. Two reactions are possible: (1) CS<sub>2</sub> + 3O<sub>2</sub> = CO<sub>2</sub> + 2SO<sub>2</sub>, (2) 2CS<sub>2</sub> + 5O<sub>2</sub> = 2CO + 4SO<sub>2</sub>. Investigation showed the presence of CO<sub>2</sub>, CO, SO<sub>2</sub>, CS<sub>2</sub> and sulfides in the combustion products, the compn. apparently depending more upon the initial CS<sub>2</sub> concn. than upon variation in the reaction.

CHARLES E. MUNROE.

The inflammation of mixtures of methane and air in a closed vessel. RICHARD VERNON WHEELER. *J. Chem. Soc.* 113, 840-59 (1918).—When an inflammable mixt. of gas and air is ignited within an inflexible closed space, flame travels throughout the mixt. in a manner and at a speed dependent mainly on the nature and proportion of the inflammable gas present. The manner in which the flame spreads through the mixt. is affected also by the shape of the containing vessel and the position of the point of ignition, and the speed of the flame is affected by these factors as well as by the intensity of the means of ignition and the initial temp. and pressure of the mixt. To such causes of variation in the manner and speed of the spreading of the flame must be added mechanical agitation or turbulence of the mixt., such as is induced, for example, within a gas-engine cylinder during the introduction of the charge. To det. the pressures, mixts. of pure CH<sub>4</sub> with air varying from 6.05 to 13.9% of CH<sub>4</sub> by vol. were fired in two spherical vessels of about 4 and 16 l. The pressures recorded varied from 2.86 atm. for 6.05% CH<sub>4</sub> steadily upward to 6.94 atm. for 9.8% CH<sub>4</sub>. Mallard and Le Chatelier's values, obtained in cylindrical vessels, are higher but rather irregular. W., believing a loss of heat and pressure due to the too gradual attainment of thermal equil., investigated this point. He concluded that a correction of 3% should be applied to his exptl. results. To trace the progress of the flame within the vessels from the time-pressure diagrams, records were taken of the time that elapsed between the passage of an electric spark at the center of a closed vessel containing CH<sub>4</sub> and air and the appearance of flame at a point 7.5 cm. vertically upwards. If it is assumed that the flames in the spheres traveled at the observed mean speeds from the point of ignition, it was found that in the 4-l. sphere no pressure was indicated until the flame traveled 5-5.5 cm. while in the 16-l. sphere flame traveled 9-10 cm. before any pressure was indicated. Therefore over the range 7.5 to 12.5% of CH<sub>4</sub>, where the flame is propagated in all directions at the same speed, about 1/4 of the mixt. had been inflamed in each vessel before any indication of pressure was obtained. The methods of experimentation and calcn. are described and illustrated.

CHARLES E. MUNROE.

GAMBLE, S. G.: How to Deal with Different Kinds of Fires. Red Book No. 201, of the British Fire Prevention Committee, 8 Waterloo Place, London, S. W. 1. 3s. 8d. post free. For review see *Chem. Trade J.* 64, 97 (1919).

**Explosives.** A. J. MARIN. Brit. 121,294, Dec. 5, 1918. In the manuf. of explosives, nitrate or perchlorate of guanidine or nitrate of dicyanodiamidine and trinitronaphthalene are added to explosives containing nitrates, chlorates, or perchlorates and nitro compds. such as liquid di- and trinitrotoluenes. An example contains  $\text{NH}_4\text{ClO}_4$  34 to 32.2, nitrate of guanidine 26 to 24,  $\text{NaNO}_3$  25 to 24.6, trinitronaphthalene 4 to 5.6, and liquid di- or trinitrotoluenes 11 to 13.6%.

**Drying smokeless powder and recovering the solvents vaporized.** L. GATHMANN. U. S. 1,289,150, Dec. 31. In the drying app. employed for driving off volatile solvents from smokeless powder, the drying compartment is so arranged that the atm. and gases from it are caused to flow to a condenser and then through a heater in closed circuit back to the drying chamber. The temp. in the condenser is gradually increased as the drying operation progresses so that in the latter stage of the drying a smaller % of the vapors are condensed than in the earlier stage. This adjustment of temp. causes retention of sufficient moisture in the surface of the explosive grains to prevent their premature hardening.

**Drying nitro compounds and recovering solvent separated therefrom.** WM. C. CRAM, JR. Can. 188,801, Feb. 18, 1919. Warm water is circulated through nitro compds. until the desired amt. of solvent is sepd. and air is passed through the compd. to carry off the aqueous moisture. The wash water is distd. to recover the solvent.

**Match composition.** W. A. FAIRBURN and F. V. D. CRUSER. U. S. 1,290,146, Jan. 7. A compn. for the "safety bulb" of "double dipped" matches is formed of  $\text{Ba}(\text{ClO}_3)_2$  26,  $\text{K}_2\text{Cr}_2\text{O}_7$  24,  $\text{Ba}(\text{OH})_2$  27, glue 12, resin 4, S 2, fillers 14 and  $\text{H}_2\text{O}$  70 parts. The first three ingredients react to form  $\text{BaCrO}_4$  and  $\text{KClO}_3$ .

## 25. DYES AND TEXTILE CHEMISTRY.

L. A. OLNEY.

**The British dye industry.** ANON. *Nature* 102, 388(1919).—Announcement is made of the amalgamation of the British dye concern, Levinstein's, Ltd., with the Government company known as British Dyes, Ltd. The new Company is to be called the "British Dyestuffs Corpn., Ltd." The outlook of the dye industry in Great Britain is thought to offer much promise. W. H. ROSS.

**Chloramine reactions of proteins.** J. F. BRIGGS. *J. Soc. Chem. Ind.* 37, 447-8R (1918); cf. Raschig, *C. A.* 2, 636; 3, 1533; Cross, Bevan and Briggs, *C. A.* 3, 1213. —All kinds of protein derivatives give the chloramine reaction regardless of their state of complexity and soly. This explains why at certain stages colloidal chloramines may be absorbed from old bleaching liquors by vegetable fibers. It also accounts for the persistent odor which clings to the hands after immersion in hypochlorite soln., and the odors observed in bleached fabrics. The caustic feeling of a neutralized hypochlorite soln. is due to the production of a chloramine and  $\text{NaOH}$ , thus:  $\text{RNH}_2 + \text{NaOCl} \longrightarrow \text{RNHCl} + \text{NaOH}$ . The reaction especially studied was the deposition of gelatin in aq. soln. on cotton yarn and fixing it in the form of an insol. chloramine. Yarn so treated retained the active Cl reaction even after thorough washing. When the gelatin-chloramine is dried in the oven it is decompd. with the evolution of  $\text{HCl}$ . The chloramine reaction serves to detect stains of protein fluids on fabrics, the presence of wool fibers in cotton, and glue or casein in adhesives or coatings. The procedure is to chlorinate, wash, and test with starch and  $\text{KI}$ . The localization of protein in plant tissues can be shown in this way. The questions raised by the author indicate the possibility of a wide field of research in the study of chloramine-protein reactions.

L. W. RIGGS.

**Water softening for textile purposes.** P. E. KING AND E. V. CHAMBERS. *J. Soc. Dyers Colourists* 34, 240-7(1918).—The authors discuss the subject with considerable detail as to processes and chemistry involved. Methods of water softening may be divided into two distinct groups: Group I: (a) the lime process, (b) soda process, (c) combined lime and soda process, which is the method in general use. Group II includes the permutite system. Local water-softening conditions of certain districts in England are discussed, also the wasting of water which by softening and some purification might not only be used again but result in reclaiming of much grease.

L. A. OLNEY.

**Korean ramie.** KASUKE UEDD AND CHUZO HIZUME. *J. Chem. Ind. (Japan)* 21, 1043(1918).—The annual production of ramie (*Bokemia nirei*) in the Orient is 3,500 tons. The fiber is on the av. 0.9 m. long and 0.2-0.6 mm. wide. The chem. analysis of the raw and finished ramie fibers, resp., are: water, 9.93, 10.59; ash, 3.84, 6.59; fiber, 62-65, 67.38; aq. ext., 7.96, 6.94; oils and waxes, 1.04, 0.35; miscellaneous impurities, 14.58, 8.15%.

T. YOSHIOKA.

**Pita fiber from Colombia.** ANON. *Bull. Imp. Inst.* 16, 289-90(1918).—A sample of "pita" fiber derived from the Bromeliaceae was examd. with the result: moisture, 9.8% (expressed on dry fiber), ash, 0.6;  $\alpha$  hydrolysis loss 12.6%,  $\beta$  hydrolysis loss 16.8%, acid purification loss 2.7%, loss on washing in H<sub>2</sub>O 2.1%, cellulose 74.7%. The fiber was of good strength, well decorticated, and could be used as a substitute for sisal hemp, or other hard fibers.

R. L. SIBLEY.

The coloring matter in *Lithospermum erythrorhizon* (KURODA) 10. Soluble oil products for use on textiles (U. S. pat. 1,289,097) 27.

**Dyes.** M. L. ANGEL. Brit. 121,347, Dec. 13, 1917. Condensation products (parazenes) are prepd. by heating 1-amino-4-halobenzene, 1-amino-4-halonaphthalene, or their derivs. substituted in the nucleus by indifferent groups, or mixts. of these compds. with condensing agents, such as ZnCl<sub>2</sub>, FeCl<sub>3</sub>, AlCl<sub>3</sub>, or P<sub>2</sub>O<sub>5</sub>, and oxidizing the products. The product from 1-amino-4-halobenzene is sol. in HOAc, the soln. dyeing wool or silk. The products form salts with acids. Auxochromic groups may be introduced into the mol. of the dyes by the usual methods. The provisional specification mentions alkyl, halo, amino, hydroxy, and sulfonic derivs., and also parazenes containing anthracene or anthraquinone nuclei.

**Colors or mordants.** W. W. COB. Norw. 29,020, Aug. 19, 1918. Colors or mordants are obtained by hydrolyzing banana or like fruit, rind, or stalks, or mixts. thereof. Cf. C. A. 13, 190.

**Solid soluble dye composition.** S. M. TOOTAL. U. S. 1,289,968, Dec. 31. A dye mixt. adapted for molding into the form of wafers or lozenges is formed by dissolving gelatin or glue in an equal quantity of H<sub>2</sub>O, adding ZnO, NH<sub>4</sub>OH or Na<sub>2</sub>CO<sub>3</sub> to neutralize any acidity of the material and boiling and afterward mixing with a dye soln. prepd. by dissolving a dye in glycerol or H<sub>2</sub>O, and again boiling. Dyes of acid, basic or direct character, may be thus prepd., e. g., magenta, erica B or xylene red B.

**Bleaching textile materials.** A. E. JURY. U. S. 1,289,803, Dec. 31. In bleaching textile materials, the material is first treated with a bleaching substance and an inorg. acid, e. g., H<sub>2</sub>SO<sub>4</sub> and CaOCl<sub>2</sub>, then with an alk. soln. such as borax or Na<sub>2</sub>CO<sub>3</sub> to neutralize the acid remaining in the material and finally with an org. acid such as HOAc to neutralize the excess alkali used.

**Keir for bleaching textile materials.** G. B. FLOOD. U. S. 1,290,156, Jan. 7. The pat. relates to structural features of a bleaching-keir, and to a method of circulating liquid through it.

**Sizing yarn or thread.** E. W. SNYDER. U. S. 1,290,795, Jan. 7. Ocotillo gum is used as a sizing on thread or yarn.

## 26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN.

**Methods of varnish analysis.** W. T. PEARCE. *J. Ind. Eng. Chem.* 11, 200-1 (1919).—Varnishes of varying compn. were made in the lab. and then analyzed by the method of Boughton (*C. A.* 10, 1277), Darner (*C. A.* 9, 1696), Twitchell, and Scott. Boughton's method gave satisfactory results for resins and oils, and McIlhiney's method (*C. A.* 2, 2630) for rosin. Analyses are tabulated. F. A. WERTZ.

**Preservative coating for iron or steel.** N. J. PORTER. U. S. 1,289,537, Dec. 31. Fe or steel is first given a coating of a bituminous material such as a bituminous paint, and over this there is applied a hot plastic mineral rock asphalt coating. The surface of the latter is roughened before it has set to a hard solid form and there is then applied a top coating formed of  $MgO$  and  $MgCl_2$ . This composite coating is elastic, impervious and resilient and adheres to the metal without the use of cleats or other mechanical means of attachment.

**Paints, varnishes, linoleum, etc.** A. A. LOCKWOOD and M. R. A. SAMUEL. Brit. 121,237, Mar. 14, 1918. In order to obtain products for use in the manuf. of paints, varnishes, linoleum, etc., fatty acids or their metallic salts, *e. g.*, ferrous linoleate, are treated with a soln. of a borate, preferably borax or Ca borate or other alk.-earth borate. The products are oxidized with or without driers. The operation may be effected by mixing the fatty acid, etc., with a borate soln., either in the cold or at temps. up to boiling. A current of air is used for oxidizing the mixt. Any of the usual paint materials, such as litharge and metallic salts, are added to the product. In order to use borates of Pb, Mn, etc., as driers, the fatty acids are mixed with acetates or other sol. salts of these metals, the mixts. being agitated and treated with air. The acetate is then converted into borate by the addition of borax soln., the agitation and treatment with air being continued. In this modification, the addition of borate soln. may be omitted if the fatty acid has been previously treated with borate soln. in sufficient quantity.

**Stenciling paper.** W. G. FUERTH. U. S. 1,289,725, Dec. 31. Stenciling sheets are formed of Yoshino paper coated with fish-isinglass hardened with dil.  $CH_3O$  soln. A backing sheet for use with this paper is formed by coating rope manila or similar paper with a mixt. containing linseed oil and kaolin or similar unctuous earthy material. When the paper is to be used for stenciling, the backing sheet is coated with a softening mixt. composed of Turkey red oil 1, glycerol 2,  $H_2O$  4 and 5%,  $CH_3O$  soln. 1 part, and the Yoshino paper is placed upon the coated backing and allowed to become softened and the two sheets are inserted together in a typewriter to produce the stencil. Instead of  $CH_3O$ , dichromates, or other hardening agents may be used.

**Indelible ink.** L. JEANMAIRE. U. S. 1,289,793, Dec. 31. An indelible ink suitable for use on paper or cloth is formed of ext. of logwood 4 oz.,  $K_2Cr_2O_7$  10 grains, alum a half oz., a soln. of nut galls 60 drops, gum arabic 1 oz.,  $AgNO_3$  2.5 drams, and  $H_2O$  1 pint. The first three and last three (of the first-named six) ingredients are separately dissolved in  $H_2O$  and the 2 solns. are then combined with each other.  $Na_2CO_3$  may be used on cloth as a mordant for the ink.

**Copying documents.** F. DOREL. Brit. 121,274, Sept. 2, 1918. A gelatinous compn. for use in the reproduction of drawings, maps, plans, or other line documents, is

rendered white by the addition of a suitable substance, so that the inked design is readily visible and imperfections in the inking are more easily rectified. The white substance, such as baryta or kaolin, may be merely mixed with the gelatin or may be produced in the compn. in the form of a white ppt., such as that of  $\text{BaSO}_4$  or  $\text{PbCO}_3$ . A metallic salt, such as  $\text{FeSO}_4$ , is added to the gelatin as usual, and glycerol, formal, or alums may also be added. A suitable compn. is prepared by adding successively to a soln. of 100 g. of gelatin in 200 g. of  $\text{H}_2\text{O}$ , the following hot solns.; (1) 70 g. of  $\text{Na}_2\text{SO}_4$  in 100 g. of  $\text{H}_2\text{O}$ ; (2) 40 g. of  $\text{BaCl}_2$  in 80 g. of  $\text{H}_2\text{O}$ , and (3) 1.5 g. of  $\text{FeSO}_4$  in 20 g. of  $\text{H}_2\text{O}$ .

**Polish for varnished surfaces.** J. G. BRIGGS. U. S. 1,289,103, Dec. 31. A compn. for polishing varnished surfaces is formed of beeswax 3, rosin 1, gum camphor 1, turpentine oil 5 and benzine 1 part. Coloring matter also may be added.

## 27. FATS, FATTY OILS AND SOAPS.

F. SCHREUBEL.

**The analysis of palm fat in the laboratory of the Public Experiment Station of the A. V. R. O. S.** F. C. VAN HEUIN. *Meded. van het Alg. Proefstat. der A. V. R. O. S., Algem. Serie* No. 2, May, 1918; *Chem. Weekblad* 15, 1394-5.—The most important detns. in the analysis of palm fat are: foreign matter, moisture and acid no. For moisture the distn. method is much to be preferred to drying at  $105^\circ$  unless there is less than 4%. Foreign matter is best detd. by dissolving the fat in hot petroleum and filtering through a Gooch crucible. Detailed directions are given for detg. the acid no. The oil should be made by heating the nuts before removing from the shell. The fermentation process, sometimes used, yields an inferior oil with a high acid no. JULIAN F. SMITH.

**Shark and ray liver oils.** MITSUMARO TSUJIMOTO. *J. Chem. Ind. Japan* 21, 1015(1919); cf. *C. A.* 12, 1004.—The liver oils are from fish caught in Japanese waters. T. confirmed the following: (1) The shark liver oils having low sp. gr. without exception contain the unsatd. hydrocarbon squalene ( $\text{C}_{30}\text{H}_{48}$ ). (2) Liver oils from some sharks not in the family *Squalidae* also contain considerable amt. of squalene. (3) The oil from the eggs of sharks likewise contains squalene. (4) The liver oil from ray and that from *Chimaera phantasma* contains no squalene. *Pristurus pilosus* produces liver oil contg. 80% of squalene—an extremely high amt. of hydrocarbon.

T. YOSHIOKA.

**Myrtle wax of South America.** ANON. *Bull. Imp. Inst.* 16, 3, 287-9(1918).—The berries of several species of *Myrica* are covered with a layer of hard wax which can be extd. by boiling the berries in  $\text{H}_2\text{O}$  and skimming off the wax which rises to the surface. This wax, when examd., showed: m. p.  $45^\circ$ , solidifying point of fatty acids  $46.4^\circ$ , acid value 21.2, sapon. value 2.167, I value 1.03%, unsaponifiable matter 0.4%. The berries are collected when they assume a light gray color, as then the yield of wax is higher and the wax is of a yellower color than when the berries are fully ripe. The wax contained 0.06% ash, and 0.31% moisture.

R. L. SIBLEY.

**Oil-filtering apparatus** (U. S. pat. 1,290,820) 1.

**Soluble oil products for use on leather or textile materials.** R. BOEHRINGER. U. S. 1,289,097, Dec. 31. Sol. products adapted for use as a substitute for Turkey red oil and other sol. oils in treating leather or textile materials, are produced by treatment of mixts. of resins and animal or vegetable oils with  $\text{H}_2\text{SO}_4$ . In one method of carrying out the procedure, 25 lbs. ground rosin is slowly added to 25 lbs. corn oil fatty

acids previously heated to about 90° and the mixt. is stirred until the rosin has completely dissolved. The soln. is then cooled and 50 lbs. of corn oil is added followed by the gradual addition, with const. stirring, of 25 lbs.  $H_2SO_4$  (66° BÉ.). Care is taken that the temp. does not rise above 35° and the mixt. is allowed to stand for 24 hrs. or until a test shows that it is sol. in  $H_2O$  (in the form of its alkali metal salts). The same treatment may also be applied to castor oil, cottonseed oil, bean oil, lard oil, cod oil, fish oils, tallow or other animal or vegetable oils or fats, and to copal, dammar, amber and other resins. The sulfonation of a mixt. of oil and resin produces a more limpid product than sulfonation of an oil alone.

## 28. SUGAR, STARCH AND GUMS.

A. HUGH BRYAN.

Some methods for the determination of the true sucrose content of molasses. T. VAN DER LINDEN. *Meded. v. h. Proefst. v. d. Java-suikerindustrie, Chem. Serie* No. 6, 1-24; *Arch. v. d. suikerindustrie v. Ned.-Indië* 1917, 1249-72; *Chem. Weekblad* 15, 1363-4(1918).—The principal methods of sucrose detn. now in use are discussed. None of the newer methods is to be preferred to the inversion method of Steuerwald, which is prevalent in Java. In some cases a combination of this with the Pellet method may be advantageous.

JULIAN F. SMITH.

The crystal balance and the figure "probable loss in molasses." F. LEISTRA. *Meded. v. h. Proefst. v. d. Java-suikerindustrie, Chem. Serie* 1917, No. 4, 1-8; *Chem. Weekblad* 15, 1362-3(1918).—The crystal balance, a special form of sucrose balance, measures sucrose only as such; but it does not indicate the form of the loss. Some indication can be gained by comparison of "probable loss" with actual loss. The crystal balance is accurate only for mechanical losses, not for chem. losses. The relations between capital loss and sucrose loss, and between probable and actual loss, are formulated and discussed.

JULIAN F. SMITH.

HARRIS, F. S.: *The Sugar Beet in America*. New York: The Macmillan Co. \$2.25.

MARTINEAU, GEORGE: *Sugar from Several Points of View*. London: W. M. Clowes & Sons.

Decolorizing-carbon from kelp. F. W. ZERBAN. U. S. 1,290,002, Dec. 31. Kelp is dried and carbonized, and C produced is heated to a high temp., (preferably to redness) and then cooled and washed with  $H_2O$  for the removal of the K salts present, and thereafter washed successively with acid, e. g., HCl, and with  $H_2O$ . The product thus obtained is suitable for use in decolorizing sugar solns. The patent is "dedicated to the public" for free use.

## 29. LEATHER AND GLUE.

ALLEN ROGERS.

Determination of moisture in leather. C. D. WILKINSON. *J. Soc. Leather Trades' Chem.* 2, 132-3(1918).—For moisture in leather better agreement and more correct results would be obtained by drying to const. wt. than by the present method of drying for 2 hrs. in a sufficiently high vacuum. The vacuum is not always the same and the amt. of moisture driven off consequently varies. For 2 hrs. drying at 98-100° at 700 mm. vacuum 13.01% moisture was obtained while at 500 mm. vacuum only

11.92% was found. When dried to const. wt. the figures were 13.48 and 13.41%, resp., for the above vacuums. In a note by the editor it is stated that no doubt higher results in moisture can be obtained by drying for a longer time than the 2 hrs. prescribed but that the present method is a compromise. Wilkinson's results show that it is important to keep the vacuum up to at least 700 mm. and it may prove desirable to increase the time of drying 1 hr. The attention of other chemists is called to the matter with the object of securing more data.

R. W. FREY.

**Titration and estimation of tannin with iodine.** F. T. LEE. *J. Soc. Leather Trades' Chem.* 3, 8-10(1919).—Difficulty in obtaining during the war pure indigo carmine for Löwenthal's method of tannin analysis led L. to experiment with other oxidation methods. A modification of Jena's I method was developed. The tannin is oxidized by 0.02 *N* I soln., the excess of which is titrated back with 0.02 *N* thiosulfate, using starch as an internal indicator. Five cc. of the filtered tannin soln., provided the soln. does not contain more than 1 g. tannin per l., are added to 25 cc. I soln. and allowed to stand for 20 mins. in a stoppered bottle. The back titration is carried out until the blue color is discharged for at least 30 secs. The oxidation figure for the non-tannin soln. must be likewise detd. and also the gallic acid figure. Five cc. of a 0.1% soln. of pure gallic acid were found by numerous titrations to absorb 4.1 cc. 0.02 *N* I soln. An example is given showing the method of calcg. the % tannin. The cc. of I absorbed by the tannin from 5 cc. of the soln. (difference between sol. solids and non-tannin titrations) is divided by 4.1 (gallic acid figure). The quotient when multiplied by the corresponding conversion factor given in Procter's L. C. P. B. gives the g. tannin per l. Results on mimosa and myrobolans by both the I method and the official method of the S. L. T. C. are in good agreement. Also in *J. Am. Leather Chem. Assoc.* 14, 114-6(1919).

R. W. FREY.

**Note on the statement of basicity of chrome liquors.** J. R. BLOCKEY. *J. Soc. Leather Trades' Chem.* 3, 11-13(1919).—The numerous methods of expressing the basicity of chrome liquors cause much confusion. Some decision should be made as to the best method for universal adoption. The European method expresses the basicity as parts  $\text{SO}_4$  to 52 Cr, while the American system uses the expression  $\text{Cr}_2\text{O}_3 \div \text{SO}_4$ . A method, believed to have been suggested by Kopecky, which defines basicity as parts NaOH required to neutralize 152 parts  $\text{Cr}_2\text{O}_3$  is used in some places. Procter (*C. A.* 13, 526) has suggested another method based on the ratio of basic to acid valencies. A very convenient arrangement in graph form shows the relationship between basicities by these various methods. The objections to the different methods are pointed out somewhat in detail. It is suggested that a method based on the number of OH groups attached to Cr, includes most advantages. Normal salts would be represented by 0,  $\text{Cr}_2(\text{OH})_2\text{SO}_4$  by 2,  $\text{Cr}_2(\text{OH})_4$  by 6, and so on. Thus the more basic the salt the higher the figures. Acid salts could be designated by minus figures, and small variations by fractions or decimals. Thus 2.5 would immediately call to mind a salt midway between  $\text{Cr}_2(\text{OH})_2\text{Cl}_4$  and  $\text{Cr}_2(\text{OH})_4\text{Cl}_4$ . The system gives a clear idea of the constitution of the salt, is independent of the acid radical, and can without modification be applied to Al and Fe salts. The formula for calcg. the basicity by this scheme is given.

R. W. FREY.

**Economy of lactic acid.** HENRY R. PROCTER. *J. Soc. Leather Trades' Chem.* 2, 121-2(1918).—Economy and the use of substitutes should be practiced as much as possible for those org. acids such as lactic, acetic, and butyric which are produced by the fermentation of foodstuffs. Formic and oxalic are the only other org. acids practically available. Of the inorg. acids  $\text{H}_3\text{BO}_3$  and  $\text{H}_2\text{SO}_4$  are suitable. The latter, if made by burning S, is very cheap and deserves more attention. If org. acids must be used in deliming a great saving can be effected by regenerating them in the used liquors

by the addition of  $\text{H}_2\text{SO}_4$ . Starting with the calcd. quantity of org. acids the liquors are subsequently mended by adding  $\frac{1}{4}$  of the calcd. amt. of  $\text{H}_2\text{SO}_4$  and  $\frac{1}{4}$  of the acid originally used. This may be repeated until the liquors become too foul. If this procedure is used with  $\text{H}_3\text{BO}_3$ , only 2 or 3 successive additions should be made before discarding,  $\text{H}_2\text{SO}_4$  is best used in about 0.5 *N* strength and run away each time. For improving the plumping power of liquors substitution for lactic acid is not easy. Mineral acids are generally not satisfactory. Formic and oxalic acids can with certain precautions be used.  $\text{H}_2\text{SO}_4$  in moderate quantities may be safely used but  $\text{H}_3\text{BO}_3$  must not be employed as it produces soft and light-weight leathers.

R. W. FREY.

Soluble oil products for use on leather (U. S. pat. 1,289,097) 27.

MOCK & BLUM: List of United States, British and German Patents Covering the Manufacture of Leather Substitutes. New York: Mock & Blum, 220 Broadway. 51 pp. \$25.

**Tanning with carbazolesulfonic acids.** E. SCHWARZ and L. BLANGEY. U. S. 1,289,280, Dec. 31. A tanning soln. is prepd. by dissolving 70 parts of Na carbazole-monosulfonate in 1000 parts of  $\text{H}_2\text{O}$  and acidifying with 70 parts of 10%  $\text{H}_2\text{SO}_4$ . Delimed hides, which may have been treated with a bisulfite soln., are immersed in this soln. until thoroughly tanned. The leather thus formed is washed and fatted as usual. The tanning may be similarly carried out with other carbazolesulfonic acids, *e. g.*, carbazole disulfonic acid or the mixt. of sulfonic acids obtained by sulfonating pure or crude carbazole or the anthracene waste products obtained by purifying crude anthracene, or sulfonic acids of chlorocarbazole or *N*-methylcarbazole.

**Tanning.** R. B. COCK and W. W. WILLIAMS. Brit. 121,325, Dec. 7, 1917. Hides are tanned in a soln. containing  $\text{Na}_2\text{S}_2\text{O}_3$ ,  $\text{Al}_2(\text{SO}_4)_3$ , vaseline or equiv. mineral product, glycerol or lanoline, tanning ext. of myrobalans, gambier, quebracho, and mimosa, and turpentine. The process may be carried out either in a rotating drum or in pits provided with agitating means. When the drum is used, the hides are first treated with the tanning ext. mixed with turpentine, and then the other four ingredients are added. In employing the pits, the treatment is started with the tanning ext., and then a mixt. of the other five ingredients is added at suitable intervals, the hides being transferred from pit to pit, which successively contain stronger solns. The hides, in each case, are afterwards immersed in a mixt. of tanning ext. and a tanning liquor, and then rinsed, piled, oiled with a sulfonated oil, and shedded.

### 30. RUBBER AND ALLIED SUBSTANCES.

JOHN B. TUTTLE.

**Depolymerization of raw rubber.** K. KAWAKAMI. *J. Chem. Ind. (Japan)*; *India Rubber World* 59, 141 (1918).—A criticism of the work of S. Takeuchi (*cf. C. A.* 12, 1351).

JOHN B. TUTTLE.

**Use of hydrometers on rubber estates.** J. C. HARTJENS. Mededeelingen van het Proefstation Malang, *Bull.* 23; through *India Rubber World* 59, 162 (1918).—Since the relation between sp. gr. and the rubber content is influenced by the tapping system as well as many other factors, Eaton's tables cannot be considered reliable for general use. Trial coagulation gives the smallest error, and this method is much to be preferred to the use of such instruments as metrolacs, latexometers, etc.

JOHN B. TUTTLE.

**Production of guayule rubber.** H. C. PEARSON. *Commerce Reports* 1918, 149; *India Rubber World* 59, 244-6, 289-91(1919).—A review of the attempts to cultivate *Parthenium argentatum*, the shrub from which guayule rubber is obtained. Figures are given showing the av. rubber content of the various parts of the plant. By judicious crossing of stocks, the yield and quality of the rubber have been greatly increased.

JOHN B. TUTTLE.

**Tentative specifications for insulated wire and cable: 30% Hevea rubber: D27-16** T. ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 650-63(1918). **Appendix I.** Extracts from standardization rules of the American Institute of Electrical Engineers. (Edition of July 1, 1915.) *Ibid* 662-3. **Appendix II.** Joint rubber insulation committee procedure for the analysis of rubber compound. *Ibid* 664-75.—Specifications covering conductors and rubber insulation are given in full detail and include methods of manuf. and chem. and phys. tests. Appendix I gives standards for cond. of Cu, high-voltage test (a) frequency and (b) rate of increase of voltage, also insulation resistance tests. Appendix II gives detailed methods for chem. analysis of rubber-insulation compds.

D. F. CRANOR.

**Tentative specifications for rubber belting for power transmission: D53-18T.** ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 676-80(1918).—These specifications cover two classes of rubber belting for transmission, viz.: (1) rubber-covered, (2) friction-covered, and include (1) manuf., (2) phys. properties and tests, (3) sizes, (4) marking, and (5) inspection and rejection.

D. F. CRANOR.

**Tentative specifications for steam hose: D54-18T.** ANON. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 681-4(1918).—These specifications cover wrapped steam hose, suitable for steam heat connections when the steam pressure does not exceed 125 lb. per sq. in. Specifications include (1) manuf., (2) phys. properties and tests, (3) sizes and dimensions, (4) workmanship, (5) marking and (6) inspection and rejection.

D. F. CRANOR.

**Physiological function of the latex in *Hevea brasiliensis* (BOBILJOFF) 11D.**

---

**Joining rubber surfaces by vulcanization.** J. L. MAHONEY. U. S. 1,289,776, Dec. 31. The pat. relates to manipulation of the edges to be joined, by stretching and compressing during the vulcanization. U. S. 1,289,777 relates to a similar process.

**Composite articles of metal and vulcanized rubber.** A. A. SOMERVILLE and M. J. RENTSCHLER. U. S. 1,289,566, Dec. 31. In the manuf. of rubber articles trimmed with metals, avoidance of tarnishing of the metal is accomplished by the use of a rubber mixt. free from S. The vulcanized rubber used may, e. g., be composed of rubber 100, flake Al oxide 100, PbO 100 and dinitrobenzene 2 parts. Other nitro compds. of the aromatic series may be used and the rubber compn. is suitable for use with metals such as brass, Cu, steel, Au or Ag.

**Rubber-like material from pinene.** L. GOTTSCHALK. U. S. 1,289,444, Dec. 31. Com. turpentine is freed from resin and the pinene obtained is heated with HCl, HOAc or other acid at a temp. of about 225-40° and mixed vapors thus evolved are passed through a metal tube maintained at a temp. of about 250° to convert the pinene into limonene. In another portion of the tube, the converted vapors are heated to about 300° or higher and maintained at this temp. until a portion of the material has been converted into a substance of rubber-like properties. The products are condensed, the acid is sep'd. and by-products are distd. off and the rubber-like residue is dried in the air at a temp. of 85° or lower. It is stated that the rubber-like material thus produced may be dissolved in benzine and generally used in the same manner as rubber.

# CHEMICAL ABSTRACTS

Vol. 13.

APRIL 20, 1919.

No. 8

## I. APPARATUS.

L. C. JONES.

Services rendered to the chemist by the blown glass apparatus of H. Vigreux. E. HILDT. *Ann. chim. anal. chim. appl.* 1, 13-5(1919).—A review. F. W. S.

The permanent marking of glass vessels. JOSEPH C. BOCK. *J. Am. Chem. Soc.* 41, 359-61(1919).—The use is proposed of glass color fused in the glass by means of an ordinary burner. E. J. C.

Gas pressure governor for one Bunsen burner. G. R. CLARE. *J. Soc. Chem. Ind.* 38, 387(1919).—The app. described was designed for the purpose of controlling the gas pressure to a single Bunsen burner without affecting the pressure on the others. It has been operating satisfactorily for several months, the pressure being controlled to 1.5 in. water column. It is shown in the accompanying figure. *A* is a brass tube 2 in. inside diam., 2 in. long, *B* a rubber stopper 2.25 in. diam., 2 in. long, *C* an ordinary glass weighing bottle,  $\frac{5}{16}$  in. diam., 3 in. long; *D* the gas inlet tube  $\frac{1}{16}$  in. diam. (containing the valve); *E* the gas outlet tube  $\frac{1}{16}$  in. diam., *F* a Pb weight fastened to the valve by a Pt wire to prevent the valve from sticking because of occasional high pressure; and *G* is a Hg seal. *H* is a  $\frac{1}{8}$  in. cork fixed on to the gas inlet tube *D* and holding a glass tube *K* drawn out to a small hole which serves as a guide for the wire *L*. The gas passes from *D* into the bell *C* through the hole *M*.

The required controlled pressure can be varied by means of the weight *F* or by placing an additional weight centrally on the top of the bell. The length of the wire (0.02 in. thick) must be detd. by expt. J. L. WILEY.

Rapid method of calibrating a stand pipet. ANON. *Gas World* 69, 399(1918).—The pipet is made from an ordinary one, having a portion of the lower tube cut off and a side arm blown on to the remaining part connecting with the bottle containing the soln. to be used. It is required to calibrate the lower tube in such a way that the amt. of liquid run out between the upper and lower calibrations will equal the stated vol. of the pipet. The pipet is clamped in an upright position and the side arm closed. A suitable jet with a rubber connector closed by a clip is fixed to the lower end. The pipet is then filled with standard acid, and the acid run down to the upper mark. Standard alkali soln., exactly equiv. to the standard acid soln., is delivered from an accurately calibrated pipet of the same vol. into a flask and two drops of methyl orange soln. are added. The acid from the pipet is then run in very slowly until the end-point is reached, when the position of the liquid in the lower part of the pipet denotes the mark required. J. L. WILEY.

Apparatus for growing crystals under controlled conditions. J. C. HOSTETTER. *Geophys. Lab. J. Wash. Acad. Sci.* 9, 85(1919).—For growing crystals suitable for pressure studies, an app. is required in which all variables affecting the rate of growth are under control. Such variables are: (1) the degree of supersatn. in the mother

liquor which at any time det. the increment of growth; therefore, temp. and evapn. which affect supersatn. must be under definite control; (2) the direction of concn. currents; (3) the number of crystals which serve as nuclei for growth; and (4) a definite circulation of the supersatd. soln. over the nuclei to be developed. Neglecting the effects of hydrostatic pressure, there are 4 methods of producing supersatn. in a satd. soln. and hence growth of a crystal immersed therein: (1) lowering (or in rare cases raising) the temp., (2) allowing the soln. to evap., (3) dissolving in this soln. held at const. temp. extremely finely divided particles of the cryst. phase, or (4) adding another solvent in slight amt. The first method is the easiest to control and the app. described is based on this principle. The app. consists of 2 thermostats connected by tubes, with the necessary stirring and circulating devices, and filled with a satd. soln. of the crystals to be studied. One thermostat, the saturator, contains the crystals, which maintain the soln. satd.; the other, the crystallizer, is held at a slightly lower temp. and it is in this cell that growth takes place. Heating is maintained in each cell by a 5-c. p. cylindrical C lamp operated through relays by thermoregulators filled with Hg. The satd. liquid is pumped from the saturator into the crystallizer where the excess material is deposited on small crystals, originally placed there as nuclei, after which the soln. is returned to the saturator. The degree of supersatn. of the soln. entering the crystallizer can be controlled by adjusting (1) the temp. difference between the saturator and the crystallizer, (2) the rate of circulation between the 2 thermostats, and (3) the temp. and the rate of flow of the cooling water in the coils which serve as a water jacket for the tube connecting the saturator with the crystallizer. The difference in temp. between the saturator and crystallizer that is permissible depends upon the change of soly. with temp., and especially upon the extent to which the soln. of a particular salt can be supersatd. As regards the effect which the number of nuclei has upon the rate of growth, it was found in one instance that with a temp. difference of 0.3-0.5° and 5 nuclei present the rate of growth for potash alum was about 1 mg. per hr. per sq. cm. of crystal surface exposed to the soln.

J. L. WILEY.

**Determining zero reading on an Ellison gage.** HERMAN BACHARACH. *Chem. Met. Eng.* 20, 246(1919); cf. Anderson, *C. A.* 13, 85.—An instrument is shown comprising a gage properly connected and mounted on a board ready to attach the pressure leads. It provides for getting the zero reading at any time in a permanent installation by using the proper valve and pipe connections instead of rubber tubing and a clamp. A scheme is also shown of connections where several differential pressures can be detd.

J. L. WILEY.

**Bibliography on pyrometers.** R. HADFIELD. *Trans. Faraday Soc.* 13, 362(1918).  
E. J. C.

**Electro-thermoregulator for water baths.** CHESTER I. HALL. G. E. Co., Fort Wayne, Ind. *Science* 49, 214-5(1919).—Attention is called to "G. E. Thermostatic Metal," a product now on the market. This is a ready made "extremely sensitive" bi-metallic strip, making a metallic thermometer suitable for a wide variety of uses, of which the regulation of water baths is only one. The material, if thin, may be made to give a motion of 6 mm. per degree; if thick, it will give a pressure of 100 g. per degree. It may be obtained from 0.13 mm. to 6 mm. thick, up to 15 cm. wide and 90 cm. long.

W. P. WHITE.

**An electro-thermoregulator for water baths.** C. H. OTIS. *Science* 48, 425-6(1918).—The majority of electro-thermostats so far devised and in use in paraffin ovens, incubators and control chambers, operate directly in the chamber itself. Such installation has its disadvantages in that the regulator is subjected to sudden variations of temp. whenever the door or compartment is opened, thus interfering with the stability and accurate operation of the app., causing an unnecessary no. of makes and breaks

with attendant corrosion of contact points. It is also conducive to fluctuations in the temp. caused by the unnecessary heating and slow cooling of the heating element. The app. described is designed to be inserted in the tubulature of the incubator, where it is immersed in the water of the water-jacket. It is intended to be used in connection with a secondary switch in circuit with an elec. heating element, in which case and with a moderate current passing through the primary circuit the thermostat will give continuous control within a fraction of a degree of the specified temp. The thin brass casing *C*, 29.5 cm. long by 2.5 cm. outside diam., is strengthened at its upper end by a collar, *D*, which extends on one side to form a rigid arm, *A*. *B* and *B'* are binding posts for wires leading to the secondary switch placed in some out-of-the-way position. They are insulated from the arm *A* by red fiber compn. *B'* is bolted to a curved saddle-piece, *S*, in which is suspended a bent lever, *L*. Pt points *P* and *P'* of generous size are soldered to *B* and *L*, resp., while a No. 3 cover glass *T* is cemented with hard shellac to the vertical arm of *L*, insulating it from the rest of the mechanism. The thermostat operates on the thermocouple principle. Zn and Fe make a sensitive combination; but Pb and Fe, Al and Fe, Cu and Fe, and other combinations, can be used, except that there is a loss of sensitiveness in the order given. Two strips *E* and *E'*, each 9 mm. wide by 6 mm. thick, are riveted together and imbedded in solder *V* at the bottom of the casing. A screw *N* and locknut *R* provide means of adjustment. This method of construction makes a rigid column which is not subject to vibration. In practice, the casing is filled with glycerol, which increases the continuity of parts and prevents corrosion of the metallic couple. The advantages are: (1) the generous length of the metallic couple insures a max. of sensitiveness; (2) this sensitiveness is increased by the mechanical advantage of the lever; (3) continued movement of the bimetallic column in either direction imposes no strain upon any part of the app. and makes accurate control possible with least adjustment for long and continuous periods of time.

J. L. WILEY.

**Acetylene generator.** H. NASH. U. S. 1,291,604, Jan. 14.

**Apparatus for concentrating vinegar and acetic acid.** E. KLEIN. U. S. 1,291,025, Jan. 14.

**Coating wooden receptacles with waste sulfite liquor constituents.** G. T. BLOOM. U. S. 1,291,696, Jan. 14. The inner surfaces of wooden receptacles are coated with concd. waste sulfite liquor or sulfite pitch of a sp. gr. of approx. 1.18, which has not been neutralized. The partly dried elastic coating thus formed renders the vessels suitable for holding oils.

**Distilling apparatus for benzene, oils, etc.** G. E. WALKER and S. H. WALKER. Brit. 121,748, Dec. 9, 1916. App. for the fractional distn. of crude benzene, oils, etc., consists of two or more stills arranged at different levels so that the liquor flows through them in succession by gravity, and which are heated to successively higher temps., each still comprizing a multitubular boiler surmounted by a fractionating column. The last and lowest still in the series is heated by steam, etc., and the preceding stills are heated either by steam or by vapors coming from the adjacent stills of higher temp. The crude liquid is preheated in a supply tank by vapors from the first of the descending series of stills. The distillates are condensed in coils. The stills may also be heated by steam coils in the liquor chambers above and below the heaters. The steam used

for heating purposes may flow through the stills in succession from the lowest to the highest in the series.

## 2. GENERAL AND PHYSICAL CHEMISTRY.

WILLIAM D. HARKINS AND E. B. MILLARD.

**The molecular weight of some salts dissolved in urethan.** G. BRUNI. *Gazz. chim. ital.* 48, II, 39-42(1918).—Stuckgold (*C. A.* 12, 876) states that urethan is a strong dissociating solvent and bases his statement on cond. detns. and on cryoscopic measurements. S. had apparently overlooked the earlier work of Castoro (*Gazz. chim. ital.* 28, II, 317(1898)) and B. and Manuelli (*Z. Elektrochem.* 1904, 601) who found the mol. wt. of  $MnCl_2$ ,  $CoCl_2$  and  $CuCl_2$  normal except for  $MnCl_2$ , which was 10% too low. S.'s results with KI in comparison with  $NH_4I$  and  $RbI$  seem strange and so B. has repeated the detns. at higher concns. and has found that the degree of dissociation  $\alpha$  as detd. by S. is much too high. B. found  $\alpha$  to be 0.10 which is very nearly the same as for  $MnCl_2$  (0.11). S.'s results with Li salicylate are also criticized.

E. J. WITZEMANN.

**The heat capacity of electro-positive metals and the thermal energy of free electrons.** GILBERT N. LEWIS, E. D. EASTMAN AND W. H. RODEBUSH. *Univ. Calif. Proc. Nat. Acad. Sci.* 4, 25-9(1918).—According to the principle of equipartition of energy the sp. heat of a solid at const. vol. per g. atom should be  $3R$  or 5.97 cal. per degree. This principle is a limiting principle and is more nearly approached in practice the higher the temp., the heavier the atom, and the weaker the constraints operating upon the atom. At high temps., however, the observed atomic heat at const. vol. for K, Na, Ca and Mg is greater than  $3R$ , and is greater in each case than that calcd. from the regular curve which fits the exptl. results at low temp., and which holds for less electro-positive elements such as Al and Cu. Also, this difference from the theoretical curve is greater for K than for Na, and greater for Ca than for Mg. These deviations of the observed from the theoretical heat capacities in the more electro-positive elements are regarded as representing the heat capacity of the more loosely bound electrons. Since at a given temp. deviations from the equipartition principle occur to an extent which is greater the lighter the particle, and the more rigid the constraint which holds it to a fixed position, then it follows that at a temp. at which other particles are gaining thermal energy approx. according to the equipartition law, the electron which is the lightest of all particles will acquire very little energy unless bound by very weak constraints. A high degree of electronic freedom in the pronouncedly electro-positive metals is also indicated by many other properties. The study of heat capacities thus offers a new method of investigating the freedom of electrons in a metal. Exptl. methods and the sp. heat data will be published in the *J. Am. Chem. Soc.* R. H. LOMBARD.

**Electron theory of passivity.** S. DEAN. *Am. J. Sci.* 47, 123-5(1919).—From Langmuir's expression for contact potential between metals (*C. A.* 11, 2304)  $V_1 - V_2 = P_2 - P_1 + (N_1/N_2)$ , where  $P_1$  and  $P_2$  are the "electron affinities" and  $N_1$  and  $N_2$  the electron concns., D. explains the "ennobling" of metals by a decrease of electrons in the surface layer. Oxidation is in effect a removal of electrons. A brief mathematical analysis serves to indicate the effect of magnetization on passivity observed by Byers and Darrin (*C. A.* 4, 1933) and shows in general why the effect is greater in the metals of the iron group. F. C. HOYT.

**A formula giving the heat of vaporization of a liquid.** E. ARIÈS. *Compt. rend.* 168, 204-7(1919).—A derivation depending on relations deduced from the Clausius equation in earlier work. Cf. *C. A.* 11, 556. R. E. HALL.

The accurate determination of surface tension, specific weight, and of electrical conductivity at very high temperatures. F. M. JÄGER. Univ. de Groningue. *Rev. gén. sci.* 30, 5-17(1919).—A review of the author's and his student's work at temps. —80 to 1650°. See *C. A.* 8, 1539; 9, 738-740, 2024, 3010; 10, 2545; 11, 414; and 12, 875, for the surface-tension methods and data. The difficulties to overcome in the measurement of cond. at high temps. consist in (1) deformation of container and electrodes because of thermal dilatation of the materials; (2) impurities incurred by reactions between container and liquid salts at high temps.; (3) contact resistance between electrode and electrolyte; (4) variable and unequal distribution of temp. in the electrolytic app. due to lack of symmetry and too great vol. The app. employed for the resistance measurements is of the form ordinarily employed in cond. measurements of precision. In the elec. furnace, the container, of Ir-free Pt, serves as one electrode, and is in the form of a hemisphere with a cylindrical prolongation. The other electrode is sym. in form, but much smaller. Both are platinized. Identical adjustment of the electrodes is obtained in every case by exactly centering them and making their relative vertical position the same by sighting across the edges with a telescope. The resistance capacity  $C$  can be calcd. at any temp. by the formula  $C = (1/0.8686\pi h) \log_{10} [R(r + h)/r(R + h)]$ , in which  $R$  is the radius of the larger electrode,  $r$  of the smaller, and  $h$  the height of the cylindrical part covered by the liquid. Calcd. and exptl. values of  $C$  are in fair agreement. Measurements have been made upon the nitrates of K, Na, Li, Rb and Cs between 310 and 560°; upon KF, KCl, KBr, and KI between 690 and 975°; and Na tungstate and molybdate between 710 and 1505°. If  $\kappa$  is sp., and  $\mu$  is mol. cond., for KF at 863°,  $\kappa = 2.948$ ,  $\mu = 90.01$ ; 975°,  $\kappa = 3.952$ ,  $\mu = 125.6$ ; KCl, at 861.6°,  $\kappa = 2.592$ ,  $\mu = 131.2$ ; at 943.5°,  $\kappa = 2.954$ ,  $\mu = 154.6$ ; KBr, 868.6°,  $\kappa = 1.904$ ,  $\mu = 112.7$ ; KI, 814°,  $\kappa = 1.438$ ,  $\mu = 103.1$ ; Na molybdate, 843°,  $\kappa = 1.411$ ,  $\mu = 107.50$ ; 1408°,  $\kappa = 2.403$ ,  $\mu = 210.61$ ; Na tungstate, 879°,  $\kappa = 1.355$ ,  $\mu = 107.38$ ; 1501°,  $\kappa = 2.453$ ,  $\mu = 221.35$ . The mol. cond. is a linear function of temp. of the form  $\mu = A + B(t - t_0)$ .

R. E. HALL.

**Electrolytic dissociation.** S. ARRHENIUS. Stockholm. *Trans. Faraday Soc.* 1919 (advance copy), 8 pp.—A review and discussion of the important supporting evidence, most of which is generally known and repeatedly discussed.

WILBERT J. HUFF.

Some investigations bearing on the present position of the ionization theory. S. F. ACRHE. *Trans. Faraday Soc.* 1919, (advance copy), 9 pp.—A review of researches since 1905 by the author and others establishing the activities of mols. of electrolytes and nonelectrolytes as well as of simple and complex ions.

WILBERT J. HUFF.

Some aspects of the electrolytic dissociation theory. NIL RATAN DHAR. Imperial College of Science, London. *Trans. Faraday Soc.* 1919 (advance copy), 13 pp.—A discussion of some of the more recent work with special attention to the hypothesis of Snethlage (*C. A.* 9, 2340, 3011). "To enumerate the services rendered by the dissociation theory . . . is to review practically the whole of exptl. work in physical chemistry . . ." Snethlage's hypothesis cannot be of much service since it does not explain satisfactorily known facts not to speak of opening up new fields of investigation.

WILBERT J. HUFF.

The determination of the ionization of an aqueous solution. W. R. BOUSFIELD. *Trans. Faraday Soc.* 1919 (advance copy), 26 pp.—A mathematical and theoretical discussion dealing particularly with the coeff. of ionization in concd. solns. The expressions  $a^2/(1 - a) = k[(h - n)/\gamma_0]_P$  (based on cond. data) and  $\delta p/p = (1 + a)/\gamma(h - n)$  (from vapor-pressure measurements) are shown to cover not only the case of the alkali chlorides, but also the exceptional case of  $\text{KNO}_3$ , when  $h$  is the number of g.-mols. of HOH per g. mol. of the solute and  $n$  is the number of g.-mols. of HOH in

combination with 1 g.-mol. of the solute,  $P$  is a const. whose value is  $1/2$  for a strong electrolyte and unity for a weak one,  $k$  is the ionization const. and  $\gamma$  and  $\gamma_0$  are functions of the concns. which at great dilns. become equal to unity and which give good results when taken in the form  $\gamma = 1 + Bm$  and  $\gamma_0 = 1 + B_0m$ , where  $m$  is the concn. in g.-mols. per l., and  $B$  and  $B_0$  are the const. which express the effect of the water reactions upon the mol. constitution of the water. The above expressions appear to be of wide, general application when considered in connection with the law of mass action; the new factors  $\gamma$  and  $\gamma_0$  express numerically the increase in the activity of the water in producing vapor pressure and the decrease in its activity in producing ionization. Thus, the high vapor pressure of concd.  $\text{KNO}_3$  solns. may be due to the action between the  $\text{KNO}_3$  and the ice mols. to give steam mols. More research on the form of the functions  $\gamma$  and  $\gamma_0$  is necessary. Future considerations must embrace true mobilities and transport numbers by the estn. of ionic sizes and vols. in relation to mobilities. Autolytic ionization in very concd. solns. must also be investigated.

WILBERT J. HUFF.

**Electrolytic conductivity in non-aqueous solutions. III. Relations between the conductivity of the solute and several physical properties of the solvent.** HENRY JERMAIN MAUDE CREIGHTON. Swarthmore College. *J. Franklin Inst.* 187, 313-8 (1919).—Study was made of the cond. of trimethyl-*p*-tolylammonium iodide in 13 different org. solvents and in aq. soln. (cf. *C. A.* 13, 88). The relationship established by H. C. Jones (the cond. of comparable equiv. solns. of binary electrolytes in certain solvents are inversely proportional to the coeff. of viscosity of the solvent in question, and directly proportional to the association factor of the solvent) held in general for this solute and the solvents used. The Nernst-Thomson hypothesis that the solvent with the higher dielec. const. should cause the greater dissociation of the solute at a given diln. was found to hold only approx. in this study. The relations considered are probably complicated by association of the mols. of the solute to form polymerized mols.

JOSEPH S. HEPBURN.

**The correction of the transference numbers of the ions of an electrolyte.** W. R. BOUSFIELD. St. Swithin's, Hendon. *Trans. Faraday Soc.* 1919 (advance copy), 7 pp.—To correct for the fact that the ions of the electrolyte carry water, the expressions  $[U/(U + V)] = n_1 + \mu(1 - a)(n_1C - n_2A)$ ,  $[V/(U + V)] = n_2 - \mu(1 - a)(n_1C - n_2A)$ , are derived. Here  $U$  = velocity of cations relative to the trough, in cm./sec.,  $V$  = velocity of anions,  $n_1$  and  $n_2$  = the actual Hittorf numbers,  $\mu$  = the concn. of the solute in gram equivalents per cc. of soln.,  $a$  = the ionization coeff.,  $C$  = the vol. in cc. of one equiv. of cations,  $A$  = the vol. in cc. of one equiv. of anions. Values for  $C$  and  $A$  are calcd. by methods given in former papers. (Cf. *C. A.* 7, 1834; 8, 285, 2290, 3294.) A table of corrections for  $\text{LiCl}$  (an extreme case) is calcd., showing that the corrections are less than the experimental errors down to normal concn.

W. J. H.

**Note on the hydration of ions.** HENRY J. S. SAND. Sir John Cass Technical Institute. *Trans. Faraday Soc.* 1919 (advance copy), 4 pp.—A criticism of the calcns. of Bousfield and Lowry (*Trans. Faraday Soc.* 3, 123 (1907)) for the detn. of the magnitude of a hydrated ion, in which are pointed out inconsistencies in assumptions by B. in calcns. comparing the size of the K ion and the HOH mol. Correcting these, S. concludes that the two magnitudes would be nearly equal. He believes, however, that the application of Stokes' formula to mol. magnitudes is inadmissible and illustrates by extending the calcns. to the size of the OH ion, which gives a value about 30 times smaller than is given by the calcn.  $(17/N) \times \text{true sp. vol. hydroxyl ion}$ .

W. J. H.

**Some recent investigations on the dilution law.** J. R. PARTINGTON. *Trans. Faraday Soc.* 1919 (advance copy), 24 pp.—A survey, though not complete, of the

literature subsequent to the paper abstracted in *C. A.* 4, 2402, with calcns. connecting developed relations and differences.

WILBERT J. HUFF.

**Complex ions.** I. M. KOLTHOFF. Utrecht. *Chem. Weekblad* 15, 1636-44(1918).—Exception is taken to the definition of complex ions proposed by de Haas (*C. A.* 13, 277), since it is too limited. For pedagogical purposes, it is better than K.'s definition (*C. A.* 12, 2480), but for scientific accuracy, the latter is preferable. K. takes occasion to reword his definition, to read as follows: Complex ions dissociate to a certain extent into simple ions, with possible formation of neutral mols. JULIAN F. SMITH.

**Properties of the colloid state and their application to industry.** W. C. McLEWIS. *J. Soc. Chem. Ind.* 38, 1-47(1919).—A brief review is given of some of the fundamental conceptions in the chemistry of colloids. There are few broad comprehensive principles. Colloid chemistry is primarily that of surface layers and capillary chemistry is not yet well developed. The work of Langmuir (*C. A.* 12, 2152) and that of Harkins (*C. A.* 11, 731, 1588) are real advances in this field. The accepted elec. theory of colloids is not entirely satisfactory. For instance, the work of Powis (*C. A.* 10, 300, 2825) indicates that the point of coagulation and point of elec. neutrality are not identical. The elec. cond. of metal colloids is greater than that calcd. from the charge on the particles. It is also 8 times greater for Pt than for Au sols. (cf. Beans and Rastlack, *C. A.* 10, 7). The Hardy-Schultze ppt. law does not always obtain because specific adsorption is also a factor. Electrically charged particles having the same sign should repel one another, but certain colloids protect others having the same sign. Colloid chemistry is badly in need of quant. work. The science is not sufficiently advanced to meet the needs of technical and biological chemistry. E. B. SPEAR.

**The colors of colloids.** II. WILDER D. BANCROFT. Cornell Univ. *J. Phys. Chem.* 23, 1-35(1919); cf. *C. A.* 13, 680.—With the aid of quotations the author reviews the laws of reflection and refraction applicable to the effect of light rays on thin films and colloidal particles. The relation of absorption to reflected and transmitted light, normal and anomalous dispersion and the effect of these on color are dealt with. Partial and total reflection and plane, circular and elliptical polarization are discussed. As a consequence of different wave length color may result from selective absorption, selective reflection, or selective refraction. E. B. SPEAR.

**Investigations on the absorption of water by gelatin.** EDITH B. SHREVE. Desert Lab., Tucson, Ariz. *J. Franklin Inst.* 187, 319-37(1919); cf. *C. A.* 13, 4.—When H<sub>2</sub>O was absorbed by gelatin, the ratio of the increase in wt. of the jelly to its increase in vol. was a const. Although the reaction is exothermic, heat favored the imbibition of water by gelatin within the temp. range 10° to 35°; the reaction attained merely an apparent, not a true equil., hence did not run contrary to Le Chatelier's theorem. When a jelly was prepd. from dry gelatin and any 1 of the following sols., or when a jelly containing 72% H<sub>2</sub>O was allowed to absorb completely 0.2 to 0.3 its own vol. of any 1 of these sols. at 10° to 35°, the subsequent rate of uptake of H<sub>2</sub>O was increased: *M* (molar) NH<sub>4</sub>Cl, *M* NaCl, *M* NaBr, 2 *M* and *M* alc., 2 *M* and *M* Na citrate, 2 *M* and *M* Na tartrate, and *M* and 0.5 *M* Na<sub>2</sub>SO<sub>4</sub>. When a jelly was prepd. from dry gelatin and H<sub>2</sub>O, then placed in any 1 of the above sols., the rate of imbibition of H<sub>2</sub>O was greater for NH<sub>4</sub>Cl, NaCl, and NaBr than for distd. H<sub>2</sub>O, and was less for alc., Na citrate, Na tartrate, and Na<sub>2</sub>SO<sub>4</sub> than for distd. H<sub>2</sub>O. "It is, then, not safe to draw conclusions regarding the effect which substances within a jelly exert upon its imbibitional capacity, when the evidence for such a conclusion lies in the known effect of an external soln. of the same substance on that same or other jellies." JOSEPH S. HEPBURN.

**The degree of dispersion of colloids and its determination.** GEORGE KING. *J. Soc. Chem. Ind.* 38, 4-77(1919).—A detailed description is given of the principles and

methods employed in the use of Zsigmondy's slit and cardioid ultramicroscope. K. was associated with Zsigmondy in the latest development of this instrument, the immersion ultramicroscope. In order that a greater magnification and a more intense illumination can be employed a portion of the microscope objective and a corresponding portion of the condenser are cut away. As a result, both the objective and the condenser, which are at right angles to each other, are immersed in the soln. An ebony cup has been substituted for the glass cuvette formerly used. Thus diffused illumination from the sides of the vessel is avoided. The smallest particles that can be counted with the old instrument have a diam. of  $5\mu$ . Particles of  $3\mu$  diam. can be counted with the immersion ultramicroscope, while even smaller particles can be seen in concd. soln. Work with the new instrument shows that previous estimates as to the number of particles in a given soln. are too low because the smaller particles could not be counted with the slit ultramicroscope. The smaller particles cannot be accurately detd. in concd. soln. owing to the diffusion of light by the larger ones. For this reason dil. solns. appear to contain relatively more particles than the more concd. In a particular case where a soln. was dild. 5 times,  $\frac{1}{5}$ , instead of  $\frac{1}{4}$ , as many particles were counted.

E. B. SPEAR.

**Retardation by sugars of diffusion of acids in gels.** JOHN ARTHUR WILSON. *J. Am. Chem. Soc.* 41, 358(1919).—A reply to the statement by E. A. and H. T. Graham (*C. A.* 13, 134) that the power of sugar to decrease the swelling of acid swollen gelatin cannot be accounted for by Procter's ion concn. theory (*C. A.* 10, 1807). P. dealt only with systems such that he could safely ignore the effects of thermodynamic environment, but if the differences in molal fugacity of sugar due to the differences in ionic concns. in the 2 phases are taken into account, P.'s theory does offer a plausible explanation of the action of sugar in repressing the swelling of gelatin.

J. A. W.

**A problem in lubrication.** W. B. HARDY. *J. Soc. Chem. Ind.* 38, 7T(1919).—Newly scraped surfaces of both solids and liquids have very different properties from those satd. with air. Raw surfaces of glass when brought together with slight pressure seize, so that considerable force is necessary to cause them to slip. Water, ether, alc. benzene and strong ammonia fail to prevent seizing. A thin film (depth about  $1 + 10^{-7}$ ) of glycerol is not so good a preventative as an excess. On the contrary thin films of acids appear to be better than flooding the surface. True lubricants stand in between these two extremes, thin films being quite as good as an excess. From these facts the author concludes that lubricants are adsorbed on the surface, and that the chem. constitution of the lubricant is the deciding factor. Lubrication becomes, therefore, a special problem in colloidal physics.

E. B. SPEAR.

**The adsorption of metals from drinking water by glass.** K. SCHERINGA. *Pharm. Weekblad* 56, 8-9(1919).—The apparent adsorption of heavy metals from  $H_2O$  soln. by glass is really only apparent. If the glass container is carefully cleaned with soap, rinsed several times with boiling  $H_2O$ , and filled while wet it will not adsorb aniline dyes from boiling aq. soln. Flasks similarly treated were filled with solns. of  $Pb(OAc)_2$  (10 mg. per l.),  $CuSO_4$  (5 mg. per l.) and  $ZnSO_4$  (10 mg. per l.), resp. No decrease in metal content could be detected after 2 days; the loss after 4 days was barely perceptible colorimetrically. Losses previously observed (*C. A.* 5, 2288) are now ascribed to pptn. by chem. reactions or to settling of fine suspensions. A little  $HOAc$  should be added to fresh samples, to prevent pptn. of  $PbCO_3$  by absorption of  $CO_2$  before analysis. The expts. of Bancelin (*C. A.* 8, 1898) on adsorption by glass are not conclusive, since the glass was not previously washed and heated.

JULIAN F. SMITH.

**Structure of crystals in extremely thin plates: a new experimental determination of the molecular magnitude.** RENÉ MARCELIN. *Ann. phys.* 10, 189-94(1918).—The

method consists in examg. plates of crystals so thin as to show Newton's ring colors by reflected light, as in a metallographic microscope, and detg. the thickness by comparison with a quartz wedge viewed between crossed nicols, using a Michel-Levy comparator. Sheets of mica of sufficient thinness were made by pressing a piece against a bit of melted Se, allowing to cool, and pulling apart. The differences in thickness between different parts of a given sheet of the mica were found to be multiples of  $0.70\mu$ , which agrees closely with the theoretical diameter of a mica mol. *p*-Toluidine crystals of similar thinness were obtained by evapg. a soln. in EtOH. In this case the differences in thickness measured were between  $0.3$  and  $0.7\mu$ , while the theory is about  $0.50\mu$ . Adjoining layers thus differ in thickness by no more than 2, and probably only single, mols.

E. T. WHERRY.

**The orientation of anisotropic liquids in contact with crystals.** II. F. GRANDJEAN. *Bull. soc. franc. min.* 40, 69-105 (1917).—Continuation of C. A. 11, 750, 1939.—About 100 instances of orientation have now been studied, and the phenomenon proves to be a general one. The relations fall into 3 types: (1) there are one or more orientations which are independent of the temp.; (2) the orientation is fairly definite, but changes sharply with the temp.; and (3) the orientation varies continuously with the temp. The 5 new liquids studied are: *p*-azoxyanisolephenetole, dibenzylidenebenzidine, di-*p*-toluylidenebenzidine, *m*-hydroxycinnamic acid, and anisal-*p*-aminoazotoluene. These were studied on cleavage surfaces of the minerals: orpiment, sphalerite, phlogopite, brucite, talc, pyrophyllite, muscovite, halite, sylvite, and leadhillite. For the detailed results the original should be consulted. Definite forces are found to exist, acting between the mols. at the surface of the crystal and those of the liquid.

E. T. WHERRY.

**The resistance of an electrolytic cell.** EDGAR NEWBERRY. Manchester Univ. *Trans. Faraday Soc.* 1919 (advance copy), 11 pp.—The total opposition to the passage of the current through a cell is the sum of the back e. m. f. and the resistance proper. The resistance proper is made up of two parts—that due to the electrolyte and the transfer resistance from the electrode to the electrolyte. N. studied this transfer resistance in a number of cells and shows it to be the greatest where gases are liberated, considerable where gaseous ions carry the current, and small when the current is carried by metallic cations and anions which dissolve the anode. High transfer resistances are favored by low current density, low temp., polished surfaces and high overvoltages. They are due to mechanical resistances opposing the penetration of gaseous ions. N. fears that much of the present data on cond. are inaccurate because transfer resistances were not perfectly eliminated and judges it unsafe to build any elaborate theory of electrolytic dissociation on the older data.

WILBERT J. HUFF.

**Chemical warfare—a new weapon.** E. HENDRICK. *Chem. Met. Eng.* 20, 152-4 (1919).—Report of an interview with Brigadier General Amos A. Fries, U. S. A. Novel views are expressed on the future of gas warfare based on the latest developments. There was a lower death rate (5%) from gas casualties than from all others.

F. W. SMITHER.

**Some problems of gas warfare.** ELLWOOD B. SPEAR. Mass. Inst. Tech. *Sci. Monthly* 8, 275-83 (1919).—The article deals with the development of offensive and defensive gas warfare. The object of the use of gas and the means taken to defeat it are pointed out. Cuts of a German gas cylinder and of German gas shells are given, while several photographs of German, French, British and American gas masks are reproduced. The advantages and defects of the various types of gas masks are discussed. The attention is also directed to some of the specific difficulties encountered in the development of the defense. A partial list is included of the gases employed in cloud attacks, gas shells and hand grenades.

E. B. SPEAR.

**The absorbent power of dry or moist earth toward chlorine gas.** DANIEL BERTHELOT AND RENÉ TRANNOY. *Compt. rend.* 168, 121-3 (1919).—Expts. were made to ascertain to what extent earth might serve as a means of protection against clouds of Cl gas. A white sand and a yellow ferruginous sand proved inferior absorbents and moisture scarcely increased their absorbent power. Humus-containing soils showed themselves much better absorbents and the absorbent power was of the same order for the different samples used. It apparently did not depend on the CaO content of the soils. The absorbent power was increased 2 to 2.5 fold by a 10% moisture content. The additional Cl absorbed when the moisture was increased to 20% was due to the Cl dissolved in the additional 10% of H<sub>2</sub>O.

### 3. SUBATOMIC PHENOMENA AND RADIOCHEMISTRY.

GERALD L. WENDT.

**Radioactivity of Italian minerals.** L. FRANCESCONI, N. GRANATA, A. NIEDDU AND G. ANGELINO. Univ. Genoa. *Gazz. chim. ital.* 48, I, 112-3(1918).—In continuing some earlier observations (*C. A.* 9, 175) many other Italian and foreign specimens have been examd. for radioactivity with a Schmidt electrometer. Minerals of Pb examd. were galena, anglesite, cerussite, phosgenite, leadhillite, pyromorphite and wulfenite; of Zn blende and calamine, of Fe pyrite and hematite, of Sb stibnite, of Sb-Fe-Ni berthierite, ullmannite, of Cu chrysocolla, malachite, azurite, chalcocite, of V vanadinite, of Cu and Fe chalcopyrite as well as molybdenite, barite, scheelite and variscite. Of these pyromorphite (varying in intensity according to physical properties, especially color), wulfenite and chrysocolla were radioactive. In the latter the radioactive material was pptd. in the  $\text{NH}_4\text{OH}$ ,  $\text{NH}_4\text{Cl}$  group. Radioactive W (from Traversella), Mn and Pb minerals were found. A malachite from Chile was intensely radioactive. Galena from Argentina was radioactive.

E. J. WITZEMANN.

**The mechanical and electrodynamical properties of the electron.** MEGH NAD SAHA. Univ. Coll. Science, Calcutta. *Phys. Rev.* 13, 35-44(1919).—The present paper is an extension of Minkowski's method of four-dimensional analysis to the investigation of the mechanical and electrodynamical problems connected with the electron. It cannot be given in a short abstract. The following subjects are taken up in turn and discussed: (1) The scalar and vector potentials of a moving electron; (2) the electric and magnetic fields due to a moving electron; (3) Maxwell's stresses, Poynting-Vector, etc., (4) the law of attraction between two moving electrons; (5) equations of motion of the electron.

F. P. PHELPS.

**Ionization and resonance potentials for electrons in vapors of arsenic, rubidium and cesium.** PAUL D. FOOTE, O. ROGNLEY AND F. L. MOHLER. Bur. Standards. *Phys. Rev.* [2] 13, 59-70(1919).—Two types of inelastic collision between the electron and atom occur in vapors of As, Rb and Cs. The p. ds. through which an electron must fall to attain sufficient energy or velocity to produce these collisions are known as the resonance and ionization potentials for the particular metal in question. For Rb and Cs the resonance potential is detd. by the quantum relation  $h\nu = eV$ , where  $\nu$  denotes the frequency corresponding to the first doublet of the principal series. A similar relation holds for the ionization potential where  $\nu$  denotes the convergence frequency of the principal series. Exptlly. detd. values of the resonance and ionization potentials for Rb were 1.6 v. and 4.1 v., resp.; for Cs, 1.48 v. and 3.9 v., resp.; for As, 4.7 v. and 11.5 v., resp. By applying the quantum relation to the results obtained with As it is possible to predict the presence of an undiscovered spectral series in As having its first term (or terms if a doublet series) near  $\lambda = 2620 \text{ \AA.}$  and converging near

$\lambda = 1070 \text{ \AA}$ . A Wehnelt tube discharge in As possesses no luminosity, indicating that the important series lines lie in the ultraviolet. At the ionization potential of Rb and Cs the principal, first, and second subordinate series appear. No ionization whatever could be detected at the resonance potentials of Rb, Cs, and As.

F. P. PHELPS.

**Ionization and excitation of radiation by electron impact in nitrogen.** BERGEN DAVIS AND F. S. GOUCHER. Phoenix Lab. *Phys. Rev.* 13, 1-5(1919).—This paper presents results obtained in further expts. on ionization and excitation of radiation by electron impacts in gases (cf. C. A. 11, 3173). It is shown that radiation can be stimulated in N mols. by electron bombardment without any appreciable ionization of the same. The value 7.5 volts heretofore accepted as the value of the ionizing potential really corresponds to the least energy an electron must have in order that it may excite radiation by the bombarded mol. There is an indication of a more intense type of radiation setting in at about 9 v. Ionization sets in at about 18 v.

F. P. PHELPS.

**Energy of the characteristic X-ray emission from molybdenum and palladium as a function of the applied voltage.** BENJAMIN ALLEN WOOTEN. Phoenix Lab., Columbia Univ. *Phys. Rev.* 13, 71-86(1919).—The relations between the energy of the lines of the K series characteristic X-radiation of Mo and Pd and the voltage between them have been studied. It was found that in each metal the  $\alpha$  and  $\beta$  radiation appeared at a certain voltage, 19.2 kv. for Mo and 24 kv. for Pd. For Mo this measured critical voltage is almost exactly that required by the Planck hypothesis to produce the  $\beta$  line, while for Pd it is that required by the same hypothesis to produce a wave length slightly shorter than the  $\beta$  line. Curves of the voltage squared *vs.* the intensities of the  $\alpha$  and  $\beta$  radiations for both metals show that these intensities vary directly as the square of the voltage for potentials not too near the critical voltage. The ratio of the intensity of the  $\alpha$  line to that of the  $\beta$  line becomes const. as the voltage is increased. The straight line parts of the curves, if produced, back cut the voltage-squared axis in the same point, and this point was found to bear the same relation to the atomic number of the metal of the anti-cathode that the point at which the curves themselves cut the axis bears, that is, the square root of the coördinate represents a voltage proportional to the square of the atomic number of the radiator. Absorption coeffs. for wave lengths of the  $\alpha$  and  $\beta$  lines of Mo and Pd in glass and in Mo and Pd, respectively, were found to vary approx. as the cube of the wave length of the radiation. The observed intensities of the  $\alpha$  and  $\beta$  lines of each metal were corrected for absorption in the glass of the X-ray tube. By application of the theory of Bergen Davis it was possible to calc. the ratio of the intensity of the  $\alpha$  radiation to that of the  $\beta$  radiation as given by a single atom. The curves obtained by plotting the theoretical equation were found to agree excellently with the exptl. curves.

F. P. PHELPS.

## 4. ELECTROCHEMISTRY.

COLIN G. FINK.

**Nature's gift to the electrochemist at Muscle Shoals.** W. G. WALDO. *Trans. Am. Electrochem. Soc.* 33, preprint; *Met. Chem. Eng.* 18, 444-6(1918).—W. outlines the complete project of development at Muscle Shoals and emphasizes the economy in its construction and the estimated low cost of power ( $1\frac{1}{2}$  mills per kw-hr.). Besides the advent of cheap power, abundance of both raw materials and labor and a mild climate offer great advantages to electrochem. industries. W. H. BOYNTON.

**Coal consumption in generating stations.** ANON. *Electrician* 82, 218-9(1919).—Data from industrial establishments in Canada and the U. S. based on a report of the Ontario Hydro-Electric Power Commission. For plants over 100,000 kw. capacity, averages  $6\frac{1}{4}$  tons per h. p. yr.; for 1000 to 5000 kw., 14 tons. C. G. F.

**Electric furnace improvements during 1918.** A. V. FARR. *Iron Trade Rev.* 64, 211-5(1919); *Blast Furn. Steel Plant* 7, 20-4(1919).—A review. C. G. F.

**Electric furnaces in the steel industry and their relation to the central station business.** ANON. *Chem. Met. Eng.* 20, 73-6(1919).—About 300 elec. steel furnaces are now operating in America. Single phase and low power factor furnaces are no longer used but furnaces taking off-peak power for steel melting and founding are popular. The article deals mainly with engineering and economic phases of steel melting. O. C. R.

**Water-jacketed electric blast furnace.** AMÉDÉE SÉBILLOT. *J. four. élect.* 27, 215(1918).—Previous installations for the elec. production of pig Fe have called for great masses of costly brickwork which rapidly disintegrated under the high temp. of the elec. arc. The author's furnace avoids all masonry near the arc. The furnace consists of a rectangular tower completely water-jacketed, similar to the water-jacketed rectangular Cu smelting furnaces used at Anaconda. At top of tower are placed the charging door, water outlet and exhaust for the hot gases. Crucible to catch melt is placed at base of tower near which is inlet for the cold jacket water. Producer gas is admitted just above the crucible and passes up between electrodes placed horizontally on each side of the tower. The charge of ore and flux (no coke) works downward between the electrodes, meeting an upward current of hot reducing gases. Used gases are exhausted by a blower placed at the top of the furnace. The length of tower can be extended at will to increase production. An estimated production of 20 tons per meter of length per day is given for such a furnace 25 meters long. Actual construction of above furnace has not yet been made. C. H. ELDRIDGE.

**Eliminating phosphorous and sulfur in electric ferromanganese furnaces.** J. LONERGAN. *Chem. Met. Eng.* 20, 245(1919).—Tabulated results are given from test run (by Iron Mountain Alloy Co., Denver, Colo.) to det. the proportions of both P and S which can be eliminated by ordinary practice. Results show that at least 98% of S is eliminated and that 52.6% of P is retained by the metal, while 31.4% of P is carried off mechanically. Based upon results found, it required 2830 lbs. dry ore to make 1000 lbs. ferro-Mn. On the basis that 52.6% of the total P charged will go with the metal, no more than  $4\frac{3}{4}$  lbs. P can be carried in 2830 lbs. ore and in about 1760 lbs. coal and limestone. Assuming coal and limestone to carry 0.34 lb. P, the ore must carry 0.17% P to produce ferro-Mn, with 0.25% P, which is the max. allowable. C. H. ELDRIDGE.

**Baily electric brass-melting furnaces.** ANON. *Elec. Rev.* 74, 438(1919).—The elec. furnace method of melting brass has made advance in the last 2 yrs., partly because of the high cost of the crucibles which are rapidly used up in the ordinary methods

of melting this alloy, and partly also because this old method has resulted in high Zn losses. The new Bailly brass furnaces are of the tilting type, 105 kw., 1500 lbs. brass, at 600 lbs. per hr.

C. G. F.

**Electrodes of carbon.** J. A. HOLDEN. *Iron Age* 102, 1485(1918).—H. points out the respective advantages of graphite and amorphous C for electrodes. The low elec. cond. of the amorphous C makes the large electrodes act as powerful insulators to the furnace roof, increasing the life of the roof materially. A jointing paste of good conducting material, such as a mixt. of finely pulverized Ceylon graphite and hot anhydrous tar of the consistency of treacle, is required. This paste is heated to 90° and smeared over the lower half of the plug, which is then screwed home. Storage of electrodes over an annealing or drying stove will help to avoid cracking, due to dampness. Electrodes burning very thin and tapering to a point are said to "point" badly. This fault causes breakage with attendant loss of time for replacements.

W. H. BOYNTON.

**The mercury process for the electrolytic production of caustic alkali and chlorine.** GINGORO YAMAZAKI. *J. Chem. Ind. (Japan)* 21, 1097(1918).—Y. introduced a new device which has advantages over the older Hg processes in respect to the amt. of Hg, current efficiency and concn. of the alkali soln. Two pairs of electrolytic chambers compose a unit (see fig.); *I, I<sub>1</sub>* anode chambers, *II, II<sub>1</sub>* cathode chambers of cement.

Fig. 1.

Sectional Elevation P—P<sub>1</sub>.

provided with perforations; *R*, outlet for the soln.; *O* and *O<sub>1</sub>*, slightly raised ends of partitions. To the cover are attached anode *A* of Atcheson graphite, Cl pipe *E*, etc. The cathodes were Fe. In each cathode chamber there is a special vertical cylinder, in which an Archimedes screw rotates. The cylinder has two apertures in the wall, one near the top and the other near the bottom, one leading to the cathodic and the other to the anodic chamber, respectively. *D* is a small compartment for solid NaCl, through which electrolyte under electrolysis flows from *I<sub>1</sub>* to *I*, or *vice versa*, in order to keep the soln. satd. A number of expts. was completed and Y. came to the conclusion that (1) the percentage of H gas in the anodic chamber gas was below permissible limit when the electrolysis temp. was raised to 40–60°. (2) The decompn. velocity of the amalgam increases with the temp. The amalgamated Na is transferred from *I, I<sub>1</sub>* to *2<sub>1</sub>, 2* and

Hg communicates with all 4 cells through paths *H, H<sub>1</sub>*; hence, the Hg in all chambers is on the same level. The electrolytes are kept sepd. by the Hg seal. *E, E<sub>1</sub>, E<sub>1</sub>'* are two subwalls in the anodic chambers, having horizontal slits at the bottom; they form small cells, 1, 2, 3, 4, between partitions and subwalls. *T, T<sub>1</sub>* = a pair of inlet pipes for electrolyte

Fig. 2.

Sectional Plan Q—Q<sub>1</sub>.

mobile Hg from which Na is removed is allowed to run from 2,2, down to 1,1. The Na content of the amalgam may be changed by changing the velocity of the suction pump. The electrolyte is introduced from outside tank through pipes T,T, through the perforations, the direction being the same as that of the flow of the Hg. The dild. salt soln. after being electrolyzed in 1 becomes satd. by passing through D, and flows into 1, is again electrolyzed and flows out through R. The subwalls in the anode chambers prevent the fresh electrolyte from mixing with the old one having Cl gas dissolved in it. As the electrolyte which comes into contact with Hg surface is concd., salt soln. containing very little free Cl, no Na in the amalgam is lost by combination with Cl. (3) When Na content of the amalgam was increased from 0.060 up to 0.203% no remarkable increase of anodic H gas was observed; it was always below 0.5%. These results prove a uniform circulation of Hg through the chambers by the new process. The electrode potential decreased with the rise of temp. and increased with the increasing Na content of amalgam. The increase of alkali content in cathodic chambers from 28 to 40% and the change of current density had a marked influence on the anodic gas composition; the current efficiency remained nearly the same, from 89 to 95%. Impure material containing a small amt. of Ca and Mg salts gave a slight increase in the amt. of anodic H, yet still below 1%, and no other striking changes were observed compared with the cases when pure salt was used. Ten kg. of Hg was used for 100 amp., with current density of 20.8 to 25.0 amp./sq. dm. There was no marked changes in current efficiency and the compn. of the anodic gas during continuous running for over 30 days and the chem. and mechanical losses of Hg were very slight.

T. YOSHIOKA.

**The future of electrolytic chlorine.** A. H. HOOKER. *Trans. Am. Electrochem. Soc.* 34 (advance copy).—The Cl industry of the U. S. has developed entirely along electrolytic lines and new uses should be found for Cl, against which the Cl can be charged at a fair operating price. Synthetic indigo, sulfur colors, picric acid, benzoic acid, etc., all point to an increasing consumption of Cl, also the use of  $AlCl_3$  for cracking petroleum oils, and the use of Cl in the treatment of ores. Also in *Chem. Eng.* 27, 3-4(1919). W. H. BOYNTON.

**Manufacture of hydrochloric acid from the hydrogen and chlorine by-products of electrolysis of metallic chlorides.** ANON. *J. four Elect.* 27, 198(1918).—In the electrolysis of alkali chlorides to produce KOH and NaOH, both H and Cl are obtained as by-products. A method is outlined by which these gases can be safely united to produce a very pure HCl. The gases are forced under pressure through porous diaphragms. An excess of H is mixed with the Cl and the mixt. is exploded by being brought into contact with incandescent C or Pt. The resulting HCl is dissolved in water and the excess H is used over again. The excess of H reduces the violence of the explosion and holds down the heat. Compression of the gases facilitates diffusion through the porous diaphragm (which ensures an intimate mixt.), increases the reaction velocity, and thus allows the use of small units. Although the heat of reaction is enough to make the process continuous, the incandescent body is always used to insure against interruption. Small and simple explosion units are used. This avoids danger of a general explosion and offers ease of repairs and replacement. Danger of back-fire is lessened by the use of small units, excess H, compression of gases, and the mixing of the gases through porous diaphragms immediately before exploding. Estimates are given of cost of installation. C. H. ELDRIDGE.

**Laboratory electrodeposition plant.** C. R. HAYWARD. *Chem. Met. Eng.* 20, 240(1919).—Description (including photograph and sectional views) of an exptl. electrodeposition plant used for instruction at the Mass. Inst. of Tech. The plant consists of 5 vats 15" long  $\times$  7" wide  $\times$  12" deep, arranged in cascade. Sides and bottom are

of slate, ends of glass to allow inspection. Each vat contains 4 anodes and 5 cathodes spaced  $1\frac{1}{2}$ " apart and arranged in multiple. The submerged area of each electrode is 6 in. square, c. d. is 10-15 amp. sq. ft. of cathode, and voltage between electrodes is 0.2-0.4 volt. A Pohle air lift provides circulation. C. H. ELDRIDGE.

**A process for electrolytically refining nickel.** G. A. GUESS. *Trans. Am. Electrochem. Soc.* 35, preprint.—An electrolytic refining of nickel containing Cu and Fe produces a Ni deposit containing but 0.001% Cu. Fe goes into soln. and accumulates, while Cu dissolves and is pptd. continuously due to a suspension of  $\text{CaCO}_3$  in the electrolyte. The salt formed from the Cu in soln.,  $2\text{CuO} \cdot 2\text{NiO} \cdot \text{SO}_3$ , settles with  $\text{CaSO}_4$  as a mud. The cathode is enclosed in a canvas bag to insure freedom from mechanical impurities. It is necessary to treat the converter mat with dil.  $\text{H}_2\text{SO}_4$  or by fusion with coke and  $\text{Na}_2\text{SO}_4$ . Three sheet-Pb or sheet-Al cathodes  $15 \times 15$  cm. are suspended in canvas bags in each tank. The electrolyte consists of  $\text{NiSO}_4$  soln. containing 5.5-6.5% Ni; it is maintained at 40-50°. A small amt. of glue is used in the electrolyte. A c. d. of 143 amp. per sq. m. of cathode gives excellent Ni with a potential of 2 v. The amp. efficiency at the cathode is 98% and at the anode around 100%. The accumulated mud is removed regularly and shows after washing and drying: Ni, 8.28%; Cu, 9.10%; S, 8.88%;  $\text{CaO}$ , 30.1%; Fe, 1.4%. The mud is reduced by fusion to a Ni-Cu mat which is dead-roasted, reduced, cast into anodes, and used in Cu refining baths for recovery of Ni as sulfate. W. H. BOYNTON.

**Military applications of electroplating.** W. BLUM. *Metal Ind.* 16, 498-9(1918).—A classification of protective coatings on metal parts of military supplies. For protection of iron and steel against corrosion, only Zn coatings should be employed. Sand-blasting is preferable to pickling in the prepn. of iron or steel for plating. The principal applications for plating upon military supplies are Zn, black Ni, and Pb. Zn deposits may be obtained from sulfate or cyanide solns., Pb from fluosilicate and fluoborate solns., and black Ni from one or two types of soln. One consists of Ni and Zn sulfates and  $\text{NaSCN}$ , and the other of Ni and Zn sulfates with addition of  $\text{NaCN}$ ,  $\text{As}_2\text{O}_3$ ,  $\text{NaOH}$ ,  $(\text{NH}_4)_2\text{CO}_3$  and possibly other constituents. W. H. BOYNTON.

ROSMAN, L. A. S.: *Nederlandsche electrotechnische kalender voor het jaar 1919*. 5th Ed. Amsterdam: van Mantgem & de Does. 596 pp. f. 1.90. For review see *Chem. Weekblad* 16, 130(1919).

SARTORI, GIUSEPPE: *La technique pratique des courants alternatifs*. 4th French Ed. Translated from the Italian by J. A. Montpellier. For review see *Rev. sci.* 57, 95(1919).

The resistance of an electrolytic cell (NEWBERRY) 2. Magnetizable alloy (U. S. pat. 1,291,408) 9.

**Storage battery electrodes.** E. J. RUEB. U. S. 1,291,167, Jan. 14. Electrode supports for storage batteries are provided with active material in paste form, with the active material is mixed with the constituents of the electrolyte to be used in the completed battery, e. g., Pb oxide, glycerol,  $\text{Al}_2(\text{SO}_4)_3$  and  $\text{H}_2\text{SO}_4$ , the electrodes are baked in an atm. of vapors from the electrolyte, cured by repeatedly dipping them in a bath of the electrolyte and finally washed with  $\text{H}_2\text{O}$  and then finished by repeatedly charging and discharging them.

**Diaphragms for electrolytic cells.** C. J. THATCHER. U. S. 1,291,253, Jan. 14. Diaphragms for electrolytic cells are formed of coarsely grained plates or cylinders of "filtros" or "alundum," the grains being bonded together only at their points of contact with each other. If the diaphragms are to be used in alk. solns. they are satd. with a soln. of a salt of a metal capable of yielding a gelatinous hydroxide, *e. g.*,  $\text{MgSO}_4$  soln., and then immersed in  $\text{NaOH}$  soln. to form a ppt. of the gelatinous hydroxide in the pores of the diaphragm, followed by immersion in  $\text{H}_2\text{O}$  to dissolve out the sol. salts, and are preserved in a moist condition, to prevent shrinkage of the gelatinous ppt., until desired for use. If the plates are to be stored for some time before use,  $\text{CaCl}_2$  or some other hygroscopic substance may be applied to their surfaces to prevent drying. The gelatinous ppt. in the pores of the diaphragm permits the free passage of ions of an alk. electrolyte but prevents access of fresh portions of alk. liquid to the diaphragm material so that the solvent action of the electrolyte is restricted to that exerted by the metal and hydroxyl ions electrolytically introduced into the plate. If the diaphragm is formed of "filtros" or other siliceous material, as soon as there is any soln., by caustic alkali, of the silica with formation of alkali metal silicate, the latter reacts with the adjacent  $\text{Mg}(\text{OH})_2$ , forming dense gelatinous Mg silicate as a coating around the siliceous particles of the diaphragm and preventing further action of the caustic alkali on them. Thus protected, "filtros" diaphragms can be used for long periods of time in hot alk. liquids without disintegration. Such diaphragms have an elec. resistance which (if they contain about 50% of voids) is about twice that of a body of electrolyte of the same dimensions as the plate. Diaphragms made as thus described cannot be used in ammoniacal nor in acid solns. For use in ammoniacal electrolytes, diaphragms are prepd. which are impregnated with gelatinous  $\text{Al}(\text{OH})_3$  or other metal hydroxide which is insol. in ammoniacal solns. Diaphragms for use with either acid or alk. electrolytes are formed by impregnating the "filtros," "alundum" or similar material with gelatinous Mg silicate or gelatinous Si hydrate.

**Electric arc furnace adapted for melting copper.** C. A. CADWELL. U. S. 1,290,902, Jan. 14.

**Effecting reactions in electric arc furnaces.** L. L. SUMMERS. U. S. 1,291,660, Jan. 14. An arc is formed in the furnace, a relatively inert gas, *e. g.*, N, is passed through the arc until it is highly heated, and a liquid to take part in the reaction, *e. g.*, liquefied O, is then injected into the arc together with a cooling liquid such as  $\text{H}_2\text{O}$ . The arc is thus extinguished and the products of the reaction are withdrawn immediately to a cooler region.

**Iron and steel manufacture.** E. HUMBERT. Brit. 121,674, Feb. 26, 1918. Fe or steel of any desired content of C, P, etc., is made in an elec. furnace from pig or cast Fe, or steel scrap, or both, by introducing the charge in a solid condition, applying the elec. current and bringing a current of air or equiv. oxidizing fluid into contact with the heated solid material, continuing the heating and the air, etc., supply until all the charge is melted, and refining the molten material to the desired product. In some cases, for oxidizing small quantities of C, the air may be applied to the molten material. Lime, and in some cases carbonaceous material or ore or other oxide, may be added to the charge. A furnace may be used which is specially fitted with air inlet ports and outlets for the products of combustion, or a furnace of the Heroult type may be used, in which air may be supplied from an ordinary blower through a pipe which is gradually raised as the charge of scrap and cast-Fe borings melts and is withdrawn when the entire charge is molten. The furnace is then closed and the refining completed.

## 5. PHOTOGRAPHY.

LOUIS DERR.

**Modern applications of photography.** ALFRED B. HITCHINS. Anso Research Lab., Binghamton, N. Y. *J. Franklin Inst.* 187, 129-46(1919).—An address, reviewing the application of photography to color-photography, spectro-photography, photomicrography, X-ray photography, and aeroplane photography. JOS. S. HEPBURN.

SCHMIDT, HANS: *Vorträge über Chemie und Chemikalienkunde für Photographierende, Ein Hilfsbuch zum Selbstunterricht für Amateure, sowie zur Vorbereitung zur Gehilfen- und Meisterprüfung für Fachphotographen.* 2nd Ed. enlarged. Halle (Saale), Germany: Wilhelm Knapp. 96 pp. M. 2.80, geb. 3.80. For review see *Chem. Weekblad* 15, 1666(1918).

**Colored medium for photographic plates or films.** S. E. SHEPPARD. U. S. 1,290,794, Jan. 7. The pat. relates to a method of forming dyed photographic color plates in which the dye is fixed in a medium from which it will not run or "bleed." The dye may be mixed with a soln. of nitrocellulose in amyl acetate emulsified with Turkey red oil and an aq. soln. of gelatin and the Turkey red oil and amyl acetate are then removed by addition of saline soln. or by a curdling by change of temp. and from the curdled material there is then formed a homogeneous emulsion of dyed particles of nitrocellulose suspended in gelatin which may be used for color screens of photographic plates and which is miscible with gelatin-AgBr emulsion. Cellulose acetate or other cellulose esters or ethers may be used instead of nitrocellulose.

## 7. ANALYTICAL CHEMISTRY.

E. G. R. ARDAGH.

**Magnetochemistry. Applications to analytical chemistry. II.** A. QUARTAROLI. Pisa. *Gazz. chim. ital.* 48, I, 65-78(1918).—In a previous paper (*C. A.* 11, 126) Q. showed how the detn. of magnetic susceptibility may be used to det. the amts. of magnetic salts present in a soln. The accuracy is as good or better than that of gravimetric or volumetric methods. Recently Q. has simplified the method so that weaker magnetic fields can be used. This makes the use of this method possible for Fe, Cr, Mn, Ni, Co and some rare elements. The process is described in detail for Fe.

The qual. test for Fe is made as follows: The 2 poles of an electromagnet having the general form given in the sketch and having semi-circular faces constitute a chamber into which an 8 mm. tube fits fairly closely so that as great a field may be obtained with the available current intensity as possible. The tube is filled with the magnetic soln. (*m*) and colored water (*d*) is added carefully on the top. On exciting the magnet the meniscus of *d* behaves differently, depending on the relative magnetic susceptibilities of solns. *d* and *m*. Since this phenomenon is clearly visible even with very dil. solns. of a magnetic salt on which water has been superposed as *d*, Q. took a known soln. of FeCl<sub>3</sub> and by observations of the behavior of the meniscus at fields of 5,000, 12,000 and 30,000 gauss he detd. the Fe content at various dilns. With the strong fields the results were accurately (0.00184%) observed at a concn. of 0.00200%. With the 5000 gauss field results were correct within 0.1% at a concn. of 0.0322%. In order to make an analysis the procedure is as follows: A suitable soln. of

$\text{FeCl}_3$  (3% Fe, for instance) containing enough  $\text{HCl}$  to prevent hydrolysis even on great diln. is prepared. A known portion of the soln. to be analyzed is boiled with a few drops of  $\text{HNO}_3$  (because the susceptibility of  $\text{Fe}^{++}$  is greater than that of  $\text{Fe}^{+++}$ ), freed from  $\text{SO}_4^{--}$  with  $\text{BaCl}_2$  ( $\text{FeSO}_4$  gives higher values than  $\text{FeCl}_3$ ) and placed in a buret. Portions of this soln. and  $\text{H}_2\text{O}$  from another buret are mixed in the tube and tested magnetically until one is obtained that behaves similarly to a known soln. prepared for the standard soln. The latter is now placed in the bottom of the tube as  $m$  and the compn. of the unknown used as  $d$  is so adjusted that the 2 layers show no change in the meniscus on exciting the magnet. By using a simple technic such as is used in weighing the adjustment of the upper soln. does not require numerous trials. If the Fe content is known approx. the analysis requires about 15 min. It is usually best to use some coloring matter in the upper soln. The presence of  $\text{Al}$ ,  $\text{PO}_4$ ,  $\text{SiO}_2$ , etc., do not interfere with the detn. of Fe in this way, but Mn and Co may. If the amt. of Mn present is small it can be detd. by one of the rapid colorimetric methods and subtracted from the value obtained for Fe without appreciable error. If Mn is present in large amts. it is better to convert it into  $\text{KMnO}_4$  (in the wet way) in which form it has practically no magnetic susceptibility. Mn in the presence of Ni and Co may be handled in the same way. In the presence of Cr the latter is first converted into magnetically little active chromates and the Fe detd. as described. The detn. of  $\text{CrCl}_3$ ,  $\text{MnCl}_2$ ,  $\text{NiCl}_2$  and  $\text{CoCl}_2$  is very similar to that of Fe by this method. With Cr and Ni the concns. of the solns. should be not less than 0.5 g. Cr per l. or 0.1 g. for the strongest fields. For Co salts the same concn. as was used for Fe may be used and for Mn even greater dilns. may be used. Good results could not be obtained with the salts of Cu. The magnetic method may also be indirectly used for inactive compds. which react with  $\text{KMnO}_4$  to produce Mn salts. In cases where the reaction products interfere with the end-point this method would be especially available. A known  $\text{MnCl}_2$  soln. is used as the standard. The detn. of Cr salts in the presence of the chromates, which are magnetically inactive, may be carried out analogously. Q. discusses the methods and difficulties of detg. ferrocyanides, ferricyanides, thiocyanates and org. compds. and describes their detn. magnetically. Ferrocyanides are diamagnetic and do not change their magnetic behavior sensibly in various concns. of  $\text{H}_2\text{O}$ . The ferrocyanides are distinctly magnetic and are easily detd. by the sensitive method here described if the concn. is as much as 0.3%  $\text{K}_3\text{Fe}(\text{CN})_6$ . Ferrocyanides are detd. by this method by oxidizing with Br water in excess and detd. magnetically. If ferricyanide was originally present also, the ferro-compd. is detd. by difference. The presence of org. compds. is without influence on the Fe detn. if the Fe is present as chlorides. To det. Fe by this method in the presence of  $\text{NH}_4\text{CNS}$  it is only necessary to oxidize the S to  $\text{H}_2\text{SO}_4$  with Br and proceed as usual.

E. J. WITZEMANN.

**Surface condensation (adsorption) of water vapor and gases, and the resultant errors in weighing.** K. SCHERINGA. *Pharm. Weekblad* 56, 94-107(1919).—Expts. with powdered paraffin,  $\text{Na}_2\text{SO}_4$ ,  $\text{NaCl}$ ,  $\text{NH}_4\text{Cl}$ ,  $\text{KClO}_4$ , pumice, etc., showed that adsorption of gases need not be considered a source of error in gravimetric work. Very fine powders, however, may adsorb  $\text{H}_2\text{O}$  vapor to a slight extent; thus, 50 g. of KBr gained 5 mg. in wt. from this cause. The literature on this subject is reviewed, and many references are given.

JULIAN F. SMITH.

**Notes on the rapid determination of lead in brass and alloys.** G. H. HOBGSON. *Chem. News* 118, 37-8(1919).—Two methods are proposed which are less elaborate and more rapid than the usual procedure. *Gravimetric method*: "Weigh out 5 g. of drillings into a 700-cc. conical beaker, dissolve in 25 cc. of  $\text{HNO}_3$  (d. 1.4), dil. with 200 cc. of water, add 20 cc. of  $\text{NH}_4\text{OH}$  (d. 0.88), or sufficient to ppt. the Cu as the hydroxide, and then add 20 cc.  $\text{AcOH}$  (80%), or enough to produce a clear soln. and leave a slight

excess of acid. Add 10 cc. of  $K_2Cr_2O_7$  soln. (3%), shake, and allow to stand for not less than 1 hr. Filter the pptd.  $PbCrO_4$  on a paper-pulp pad, wash with water to remove the bulk of Cu, pour on the pad hot douches of 30%  $H_2SO_4$  (about 40 cc. will be required) until the yellow chromate is completely converted to  $PbSO_4$ , and give a final washing with cold water. (A few drops of EtOH added to the pad before the  $H_2S$  will prevent any difficulty in conversion.) Take up the  $PbSO_4$  in hot  $AcONH_4$  soln. (containing free AcOH) by pouring about 40 cc. or so on to the pad and washing through into a clean 300-cc. conical beaker, bring soln. to the b. p., and carefully ppt. as  $Pb-MoO_4$  by the gradual addition of  $(NH_4)_2MoO_4$ , allow to settle, filter through an ashless paper pad, wash with water containing a little  $AcONH_4$ , ignite, and weigh as  $PbMoO_4$ . It is best to add the  $(NH_4)_2MoO_4$  a little at a time to be sure of complete pptn. Also when the Pb content is below 0.25%, the chromate pptg. is best done by adding the chromate after pptg. the Cu as the hydroxide and before the addition of AcOH. A complete analysis can be made in 4 hrs. *Volumetric method*: "The operations as far as the pptn. of the Pb chromate are the same as in the above. Filter the  $PbCrO_4$  on a paper-pulp filter and wash with warm dil. AcOH (5%) and water until free from Cu salts and excess chromate. Pour on to the pad cold HCl (1:4, free from Cl), allow to run into a clean 400 cc. conical beaker, and wash well with cold water until all chromic acid is completely washed through. The soln. will now measure about 150 cc. and will contain practically all the Pb as  $PbCl_2$ . The yellow chromic acid may now be titrated by either of the ordinary methods." It only requires about 2 hrs. for this method. Both methods show excellent checks with the gravimetric fuming method.

ERLE M. BILLINGS.

**Project for the unification of the methods of analysis of iron and steel.** A. MARI-NOT. *Ann. chim. anal. chim. appl.* 1, 5-10(1919).—M. recommends the following methods to the French Chemical Society: *Total C*: Wiborg method: direct combustion in elec. furnace, absorbing the  $CO_2$  in NaOH soln. and titrating back with  $H_2SO_4$  and phenolphthalein; Mahler and Goutal method (cf. *C. A.* 5, 3779; 6, 2727). *Silicon*: Practically the Drown method ( $HNO_3-H_2SO_4$  mixt.). *Manganese*: The method of Travers (cf. *C. A.* 11, 2866; 12, 1028). *Phosphorus*: The alkalinimetric method. *Sulfur*: The Rollet-Campredon process (igniting in a current of  $H_2S$ -free  $CO_2$ , and H, absorbing the  $H_2S$  formed in  $(AcO)_2Zn$  soln. and titrating with I and  $Na_2S_2O_3$ ). *Arsenic*: The Hollard and Bertiaux method (cf. *Ann. chim. anal.* 1900, 241) based on the distn. as  $AsCl_3$  and titration with I soln.

F. W. SMITHER.

**Note on the analysis of barite.** FRENKEL. *Ann. chim. anal. chim. appl.* 1, 10-2 (1919).—As  $BaSO_4$  is generally used for the manufacture of  $BaCl_2$ ,  $Ba(NO_3)_2$ ,  $BaCO_3$ ,  $BaO_3$ , and lithopone, its com. value in such cases should be based on the Ba content after reduction, although some  $BaSO_4$  may escape reduction and some Ba may be held as insol. silicate and as  $BaSO_3$ . To det. Ba heat 1 g. of the finely powdered barite in a Rose crucible to bright redness for 15 min. in a current of illuminating gas, let cool in the gas current, and leach with boiling  $H_2O$ ; filter, wash, acidify with dil. HCl, expel  $H_2S$  and ppt. the Ba with dil.  $H_2SO_4$ . If the barite contains  $CaSO_4$ , the latter should be removed before detg. total Ba, or sol. Ba after reduction, by treating 1 g. of the finely powdered mineral with 50 cc. of  $H_2O$  at  $38^\circ$ ; then det. Ca in the aq. ext. and Ba in the residue. F. has had samples of barite containing as much as 10% of org. matter.

F. W. SMITHER.

**Determination of nitrites.** F. DIENERT. *Ann. chim. anal. chim. appl.* 1, 4-5 (1919). Unless air is excluded the iodometric method ( $NaNO_2 + 2HI = NaI + I + NO + H_2O$ ) gives results 10 to 15 times too high. To obviate this D. operates as follows: Pass a current of  $CO_2$  from a Kipp generator through a soln. of  $NaHCO_3$  in a flask, then into a flask containing 50 cc. of 4% KI soln., and finally into a flask

containing the nitrite soln. and provided with a separatory funnel; the exit tube from this flask dips into  $H_2O$ . After 15 min., introduce 10 cc. of  $N H_2SO_4$  through the funnel and lower the exit tube from the second flask so that the  $CO_2$  will force the  $KI$  soln. over into the nitrite soln.; then introduce through the funnel 10 cc. of 20%  $(NH_4)_2CO_3$  soln.; disconnect the last flask and titrate the free  $I$  with 0.143  $N As_2O_3$  soln. (the  $H_2SO_4$  and  $(NH_4)_2CO_3$  are freed from  $O$  by  $CO_2$  before use). The max. error with 3 mg. of  $N$  as nitrite is 2%. Also in *Compt. rend.* 167, 366-7(1919). F. W. SMITHER.

**The accurate determination of carbon monoxide in gas mixtures.** J. IVOR GRAHAM. *J. Soc. Chem. Ind.* 38, 10-4T(1919).—Methods of estg.  $CO$  based on the reaction  $5CO + I_2O_5 = 5CO_2 + I_2$  are capable of giving exceedingly accurate results. Some modifications are proposed in procedure and app. described in *C. A.* 9, 183. Full details are given of methods for gas mixts. containing  $CO$  in various proportions and for the application of these methods either in the lab. or in the field. Line drawings are shown of the modified Haldane's app. for the lab. and field. ERLE M. BILLINGS.

**A rule for chemical calculations.** PAUL NICOLARDOT. *Chimie et industrie* 2, 25-6(1919).—A meager description accompanied by poor cuts of a rule by the aid of which one or two operations can be saved in some calcns. ERLE M. BILLINGS.

**The alkali iodides as reagents for cadmium and nickel.** A. AGRESTINI. Univ. Urbino. *Gazz. chim. ital.* 48, II, 30-4(1918).—Salvadori (*C. A.* 10, 1483) showed the value of the ammoniacal metallic perchlorates in the detection of  $Cd$  in the presence of  $Cu$ , and of  $Ni$  with  $Co$ .  $Cd$ ,  $Ni$  and  $Co$  in ammoniacal solns. behave similarly with alkali iodides. A soln. of  $Cd$  salts strongly ammoniacal treated with a 20-30% soln. of  $KI$  gives a white heavy ppt. of  $Cd(NH_4)_2I_2$  at once in concd. solns. and slowly in more dil. ones. The salts of  $Cu$  under similar conditions give no ppt. except when mixed with  $Cd$ , and the ppt. is then due to the latter. This ppt. may be washed, on the suction plate, with small amts. of dil.  $NH_4OH$ , then  $EtOH-NH_4OH$ , then 94%  $EtOH$  and dried in a desiccator over  $CaO$ . The ppt. is the  $Cd(NH_4)_2I_2$  discovered by Rammelsberg and obtained by Naumann (*C. A.* 4, 1851) by the action of  $NH_3$  on  $AcOEt$  solns. of  $CdI_2$ . Even in strongly ammoniacal solns. of  $Ni$  salts the concd. alkali iodide solns. give copious ppts. of bluish violet heavy  $Ni(NH_4)_2I_2$  and, as in the case of the  $Cd$  pptn., this is nearly quant. This compd. is also subject to hydrolysis, but may be handled as described for the  $Cd$  salt. Pptd. from fairly concd. solns. it is blue-violet in color, but is it nearly white when pptd. from solns. of say 1 g.  $Ni(NO_3)_2 \cdot 6H_2O$  in 2 l.  $H_2O$ . Solns. containing  $Co^{+}$  ions similarly treated give a yellow-red ppt. having a similar compn. probably. This test may not be used directly to detect  $Ni$  in the presence of  $Co^{+}$ . By previously transforming the  $Co^{+}$  into cobaltamine with  $H_2O_2$ ,  $NH_4OH$ , etc., the  $Ni$  could generally be satisfactorily sepd. with alkali iodide as  $Ni(NH_4)_2I_2$ , but it was better first to sep. the  $Co$  as potassic cobaltic nitrite or to remove it by Vogel's reaction with  $NH_4CNS$ . After this treatment the test was always satisfactory. The alkali bromides react with ammoniacal  $Ni^{+}$  and  $Co^{+}$  solns. to give ppts. that are probably  $Ni(NH_4)_2Br_2$  and  $Co(NH_4)_2Br_2$ , resp., having a similar color, but they are more sol. in  $H_2O$  than the  $I$  compds.  $Cd$  does not give an appreciable ppt. with alkali bromides. E. J. WITZEMANN.

**Pyridine and ammonia, estimation and separation—an application of the electrolytic dissociation theory.** E. B. R. PRIDEAUX. *Trans. Faraday soc.* 1919 (advance copy), 10 pp.—Methyl red, lacmoid, litmus, red cabbage, *o*-nitrophenol, lacmoid, or any other indicators or mixtures of indicators changing between the exponents 4 and 8 are suitable for the titration of pure ammonia solns. Pure pyridine solns. are best titrated with  $HNO_3$  in the presence of Congo. Methyl violet gives much the same result. In mixts. of the 2 bases,  $\alpha$ -naphtholphthalein (cf. Werner, *C. A.* 12, 677) is

used for the ammonia and the end-point is taken at the color change from blue to greenish blue or nearly colorless; for the pyridine, Congo is then added and the  $\text{HNO}_3$  addition continued until the reddish color changes to a purple brown. In such mixts., the results for ammonia are satisfactory but tend high, while pyridine shows a high alkalinity in the presence of  $\text{NH}_4$  salts. The bases may be sepd. and estimated by distn. as follows: To the mixt. normal  $\text{HNO}_3$  is added until Congo turns purple, then di-Na H citrate (about 0.4  $M$ ) until the color is red-brown. The soln. is then distd. through a splash bulb and condenser into a water-sealed exit. The first 50 cc. may be collected in normal  $\text{HNO}_3$ . More citrate is added if the soln. is blue and more Congo if this is pptd. Successive distillates are collected in open flasks or beakers until they contain no pyridine. The distg. flask is then treated with an excess of alkali. The pyridine, pyridine-ammonia mixts., and ammonia obtained in the various distillates are then titrated as above. The method was developed by the aid of calcs., based upon the electrochem. theory.

WILBERT J. HUFF.

**Micro elementary analysis of organic substances.** J. V. DUBSKY with E. DINGEMANSE and A. GLATTFELDER. Univ. Zurich. *Helvetica Chimica Acta* 2, 63-75(1919).—(a) *Micro-Dumas*: It was found that  $\text{CO}_2$  from a Kipp app. is inferior to that obtained by heating a tube of  $\text{NaHCO}_3$  because of the absorbed and adsorbed air in the former; any leaks in the app. cause high results. A new form of micro-azotometer is described and illustrated in which only a small amt. of Hg is necessary as a seal; the addresses of firms supplying this piece of app. are given. (b) *C and H determinations*: For compds. containing nitro groups the previously described tube was used with an oxidized Cu spiral before the combustion boat as in macro analysis; explosive substances as picric acid and trichlorodinitrobenzene were found to give high values; this was partially overcome by the use of  $\text{PbO}_2$  (cf. following abstr.). Explosive nitro compds. may also be analyzed by placing a boat containing a known wt. of benzoic acid or sucrose before the boat with the nitro compd.; these substances act as reducing agents and partially reduce the CuO which then functions as a reduced Cu spiral; the wt. of  $\text{CO}_2$  and  $\text{H}_2\text{O}$  is then corrected by an amt. equal to that calcd. from the known quantity of benzoic acid or sugar used (cf. *Am. Chem. J.* 23, 343(1901)). Reduced Cu spirals should never be used in micro-analysis because even when dried at  $120^\circ$ , the Me alc. reduced spirals still contain sufficient amts. of formaldehyde to give poor results; spirals reduced with H still have traces of adsorbed water.

N. A. LANGE.

**Micro elementary analysis of compounds containing sulfur, halogen or nitro groups. The double combustion.** CH. GRÄNACHER. Univ. Zurich. *Helvetica Chimica Acta* 2, 76-84(1919).— $\text{PbO}_2$  is used to remove the S, Cl and  $\text{NO}_2$  groups. A somewhat longer tube than usually employed in micro-analysis is filled at the absorption end with  $\text{PbO}_2$ , followed by sections of Ag wire, CuO and  $\text{PbCrO}_4$  mixt., then a second Ag wire. The  $\text{PbO}_2$  end of the tube is surrounded by an aniline jacket fitted with a reflux condenser which maintains the temp. of the  $\text{PbO}_2$  at  $175-80^\circ$ . At the beginning of the combustion the aniline is heated to boiling after which heating is no longer necessary because of the heat supplied through the combustion tube during the analysis. In this manner the temp. at which  $\text{PbO}_2$  is most effective is automatically maintained. The double combustion is nothing more than two combustion tubes placed within the same furnace, each connected to the usual absorption app. In this way the time for many analyses is considerably shortened.

N. A. LANGE.

**Publications on military sanitation.** 72. Contributions from the hygienic-chemical research laboratories, Pt. IX. *Pharm. Weekblad* 56, 74-7(1919).—This publication describes the work of various German military pharmacists, carried out in different institutional and camp laboratories during the war. Ten contributions are reported: 1. The detection of free sulfuric acid in leather, especially after the use of artificial tanning

*agents.* H. STRUNK and O. MATTHES.—To det. free  $H_2SO_4$  in leather, add  $HNO_3$ , add a known amt. of  $Mg(NO_3)_2$  and ignite until all the Mg is converted to  $MgO$ . Detn. of the amt. of  $MgO$  left will show the amt. fixed by  $H_2SO_4$ . Artificial tanning agents, as Neradol D or ND, Ordoval G, sulfite cellulose lye, etc., often contain  $H_2SO_4$  either free or in org. combination. In either case it is harmful to the leather and should not be overlooked. 2. *The analysis and evaluation of tinned meat.* H. SERGER.—Rubber and paper packing rings were examd. with reference to compn., chem. and physical properties, behavior on sterilization, stability to boiling in different solns., etc. Paper rings are an excellent substitute for those of rubber. Methods of analysis of the cans and their contents are also discussed. 3. *Marmalades and war jams.* H. SERGER.—Studies of consistency, taste, chem. compn., relation of sugar content to stability, etc. 4. *Preserving vegetables in kegs, and a comparison of their composition.* H. SERGER.—Vegetables can be preserved by acid formation (as sauer kraut), by salting down, or by means of chem. preservatives. The last is preferable;  $NaOBz$ , with a few % of  $NaCl$ , is recommended as the preservative. With the salt method, there is considerable loss in washing out the brine. 5. *The loss of fat and sugar in baking biscuit and pastry.* E. ALPERS.—The loss of fat in baking is negligible; the loss of sugar does not exceed  $1/7$  of the amt. originally present. 6. *The analysis of kitchen and table ware and of tins for canned foods.* E. SEEL and K. HILS.—Too much Pb (1.27–4.44%) was found in 15–20% of the tin coatings examd. No Pb was found in enameled coatings, but a few contained Zn. Some ware is enameled with bakelite. If prolonged treatment with 40% EtOH exts. no PhOH from such ware, it is satisfactory. In normal times, tin cans had 2.0–2.5 mg. of Sn per sq. cm., but in the latter years of the war, they had only 1.0–1.5 mg. per sq. cm. 7. *The microscopic detection of food and drink adulterants and substitutes of vegetable origin.* C. GRIEBEL.—A discussion of adulterants and substitutes for bread, flour, marmalades, etc., spices, coffee, tea, and tobacco. 8. *The juice of the Russian cranberry.* C. GRIEBEL and A. SCHÄFER.—The glucoside vaccinin, monobenzoylglucose, was found in cranberry ext. captured from the Russians. This glucoside had been previously found in the fruit of several varieties of *Vaccinium*. 9. *The evaluation of cresolin-cresol and crude cresol solutions.* H. FINCKE. A 1–2% soln. of cresol or cresol and Na cresotate is particularly adapted to the disinfection of articles of wool and leather. The analysis of such solns. is discussed. 10. *The preparation and purification of fat from bones.* D. SCHENK.—Describes 2 methods of prep. an edible fat from bones. JULIAN F. SMITH.

#### Preparation of soluble starch (LEULIER) 28.

EYDMAN, F. H., JR.: Tabellen voor het scheikundig onderzoek van anorganische stoffen. 7th Ed. Delft: J. Waltman, Jr. 38 pp. f. 2.60 + 10% toeslag. For review see *Chem. Weekblad* 16, 131(1919).

## 8. MINERALOGICAL AND GEOLOGICAL CHEMISTRY.

EDGAR T. WHERRY AND J. H. BOWER.

Contribution to the mineralogy of boron, lithium and thallium in volcanic exhalations. ALBERT BRUN. *Bull. soc. franc. min.* 40, 107–10(1917).—The salts produced by the eruption of Vesuvius in 1906, consisting of  $NH_4(Cl, F)$ , show the flame color and spectrum of B. The leucite-tephrite rock of Vesuvius contains Li, and this has also been obtained as  $LiCl$  on evapg. a  $H_2O$  extract of the scoria of 1906. Tl occurs in all fumarolic salts, As-sulfides, and red scorias of Vesuvius, and has also been detected in

the  $\text{NH}_4$  compds. at Chinyero, Teneriffe, and in red scoria at the Spagnuolo crater, Etna. The Tl occurs in sol. and insol. compds., in S, and in unknown compds. The amts. of these elements are about 1 or 2/4000. The compds.  $\text{Tl}_2\text{S}$  (and  $\text{TlCl}$ ) should be recognized as minerals of volcanic origin. E. T. W.

**The thioarsenides of the Binnenthal.** ALBERT BRUN. *Bull. soc. franc. min.* 40, 110-1 (1917).—Spectroscopic tests made on the thioarsenides from the Binnenthal have shown the presence of Tl in every case, although no Tl-bearing mineral could be detected as an admixture. This occurrence is analogous to that at Vesuvius.

E. T. W.

**A remarkable occurrence of chromium tourmaline and rutile in the Barberton District.** A. L. HALL. *Trans. Geol. Soc. S. Africa* 20, 51-2 (1918).—An occurrence of green Cr-tourmaline with pink rutile and talc is described. It forms a coarsely crystd. green rock, associated with talcose schists and serpentine in which occur many narrow bands of grayish gneissic offshoots from intrusive granites. S. G. G.

**A noteworthy occurrence of biotite mica.** EVAN R. STANLEY. *Trans. Proc. Roy. Soc. S. Australia* 40, 268-71 (1917).—The black biotite associated with "davidite" when exposed to atmospheric conditions for a few months becomes coated with carnotite. The mean of 3 analyses gave:  $\text{SiO}_2$  38.66,  $\text{Al}_2\text{O}_3$  17.33,  $\text{Fe}_2\text{O}_3$  9.85,  $\text{FeO}$  5.59,  $\text{MgO}$  14.97,  $\text{CaO}$  none,  $\text{Na}_2\text{O}$  2.76,  $\text{K}_2\text{O}$  5.59,  $\text{H}_2\text{O}$  (chiefly loss on ign.) 2.47,  $\text{TiO}_2$  (combined) 0.03,  $\text{TiO}_2$  (included rutile needles) 1.32,  $\text{Cr}_2\text{O}_3$  0.61,  $\text{MnO}$  tr.,  $\text{F}$  0.77,  $\text{V}_2\text{O}_5$  tr., sum 99.95, less O 0.32 for F = 99.63%. S. G. GORDON.

**Mineral notes.** D. MAWSON. *Trans. Proc. Roy. Soc. S. Australia* 40, 262-6 (1916).—Monazite occurs associated with tourmaline, apatite, cordierite, autunite, torbernite, zeunerite, gummite and carnotite in a corundum-mica-schist between Mounts Pitt and Painter, in the Flinders Range; it is apparently the result of the action of gaseous or liquid magmatic solns. on the surrounding rocks. Cordierite, sillimanite and spinel also occur in the corundum-mica-schist of the district. Titanite occurs in large crystals in a gabbro pegmatite below Mount Gee. Australian occurrences of octahedrite, gypsum, lodestone, and davidite are noted. S. G. GORDON.

**Chemical notes on davidite.** W. T. COOKE. *Trans. Proc. Roy. Soc. S. Australia* 40, 267 (1917).—Davidite occurs in radioactive ilmenite, with magnetite, rutile, biotite and carnotite, at Radium Hill, 20 miles E. S. E. of Olary Sta. Analysis gave:  $\text{TiO}_2$  54.3,  $\text{FeO}$  16.0,  $\text{Fe}_2\text{O}_3$  13.0, rare earths 8.3, ( $\text{V}_2\text{O}_5$ ,  $\text{Cr}_2\text{O}_3$ ,  $\text{U}_3\text{O}_8$ ) 4.6,  $\text{MgO}$  0.6,  $\text{CaO}$  1.5,  $\text{PbO}$  1.1,  $\text{CuO}$  tr.,  $\text{H}_2\text{O}$  1.5, sum 100.9%. The rare earths contain much Ce, but little Th. The presence of La, Di, Er, Yt and Sc was shown chemically or spectroscopically; Zr is absent. On heating to redness, 100 g. yield 15 cc. He. S. G. G.

**Chemical properties of Utah hydrocarbons.** C. BARDWELL, B. A. BERRYMAN, T. B. BRIGHTON AND K. D. KUHR. *Trans. Utah Acad. Sci.* 1, 78-95 (1918).—About 15 hydrocarbons occur in Utah, 5 of which were investigated: gilsonite, tabbyite, wurtzellite, ozokerite, and rock asphalt. Gilsonite (uintaite) is limited to the Uncompahgre Reservation, Uinta Co., occurring as filling in vertical fissures in the Green River (Eocene) calcareous shales, limestones and sandstones. Tabbyite occurs in the Tabby Canyon, Uinta Co., in vertical fissures in Upper Tertiary sandstones and shales. Wurtzellite (elaterite, mineral rubber) occurs in an area of 100 square miles between Indian Canyon and Sam's Canyon, north of Price, in vertical veins 1 to 22 in. wide, with a max. length of  $3\frac{1}{4}$  miles, midway in the Green River formation. Ozokerite (mineral wax) occurs in an area west of Cotton, Utah Co., in shales, shaly sandstones, and limestones, in the lower part of the Wasatch Formation (Tertiary), chiefly in fissures and spaces in zones of brecciation and jointing. Rock asphalt (bituminous sandstone) occurs in large deposits south and east of Vernal, southeast of Thistle, near Sunny-

side, at the head of Willow Creek, near Jensen, west of Clear Creek, and north of Colton. In the field one asphalt gradually changes to another. There may be a genetic relation among the hydrocarbons. The physical and chem. properties of the 5 hydrocarbons are tabulated, also their soly. in various solvents, the results of fractional distn., with 8 analyses of their ultimate compn. The literature on the deposits is reviewed, and the uses of the hydrocarbons are listed. S. G. GORDON.

**Microscopic secondary sulfide enrichment in the "Kuromono" ore from the Kosaka mine, Province Rikuchu, Japan.** TAKEO KATO. *J. Geol. Soc. Tokyo* 25, No. 295, 1-7(1918).—A microscopic intergrowth of bornite, chalcocite and covellite is described, occurring as secondary sulfides deposited by descending cupriferous solutions. The bornite and chalcocite were formed contemporaneously at the expense of pyrite and chalcopyrite, while in some places bornite has replaced chalcocite. S. G. G.

**The veins of Chañarcillo, Chile.** W. L. WHITEHEAD. *Econ. Geol.* 14, 1-45(1919).—The geology of the district is fully discussed. The primary ores were first deposited in veins from solns. of probable igneous origin and were arsenides, thioarsenides, and thioantimonides of Ag, along with gang minerals. Subsequent repeated oxidations and enrichments by supergene solns. of atmospheric origin during a period of erosion gave rise to the bonanza ore bodies, composed of chlorides, bromides and iodides of Ag, native Ag, and dyscrasite in the upper zone and native Ag, dyscrasite, argentite, stephanite, and other sulfides in the lower zone. A bibliography and several photomicrographs are appended. A. B. PECK.

**The ores of manganese and iron of the crystalline massif of Brosteni, Roumania.** V. C. BUTUREANU. *Bull. soc. franc. min.* 40, 164-77(1917).—The geology of the region and occurrence of the ores are described and methods of analysis given. Analyses of Mn-Fe carbonates from several localities show approximately a constant ratio, Mn:Fe = 5:1, and the name "ponite" is applied to these. Another carbonate had the ratio 1:2. Alteration products of these minerals are shown by a number of analyses to have the general formula  $RO \cdot xMnO_2 \cdot yH_2O$ . Such material is termed brostenite. The use of these substances as ores is discussed. E. T. W.

**Experiments relating to the enrichment of tungsten ores.** R. W. GANNETT. *Econ. Geol.* 14, 68-78(1919).—The purposes are to det. (1) the effects of various solns., found in ground waters, on W minerals, and (2) what natural reagents might ppt. W from soln. Only commercial ores, scheelite and the wolframite series, ferberite—hübnerite, are considered. The results of a large number of leaching and pptn. expts. with chlorides, carbonates, sulfates, alkali hydroxides and combinations of these are tabulated and discussed in their relation to field evidence. The general conclusions are: associated minerals usually dissolve more easily than W minerals, and enrichment comes about by the removal of worthless material. W minerals may dissolve, forming sol. salts and colloidal solns., and remove W from the outcrop. W may be leached from ores and not be redeposited below. The ease with which W compds. hydrolyze and form insol. compds. tends to prevent downward migration of W, and there probably are no extensive zones of W minerals as in the case of Cu or Ag, although enrichment by soln. and repptn. probably does occur somewhat.  $Fe_2(SO_4)_3$  slows down and stops soln. and migration of W. Secondary W ores are usually hübnerite and wolframite, rather than scheelite. A. B. PECK.

**The barite deposits of Missouri.** W. A. TARR. *Econ. Geol.* 14, 46-67(1919).—See C. A. 13, 551-2. A. B. PECK.

**A system of petrography.** S. J. SHAND. *Geol. Mag.* 4, 463-9(1917).—S. reviews the mineralogical classification of igneous rocks of Holmes (C. A. 11, 3215) and proposes a modified system based on the degree of satn. of the rock with regard to silica.

Five main divisions occur: (1) Oversaturated rocks (containing free quartz), (2) satd. rocks, (3) unsatd. rocks: (a) dyad and triad metals unsatd., (b) monad metals unsatd., (c) both monads and dyads unsatd. The following taxonomic factors are applied: the degree of satn. as above noted, the double ratio of orthoclase-albite-anorthite, the color ratio of light to dark minerals, crystallinity, ratio of specific minerals, and finally trivial characters of mineralogy and texture, giving varieties.

\* S. G. GORDON.

**The petrography of Arran.** 3. Pitchstone xenoliths in basalt dyke, Dippin, Arran. G. W. TYRRELL. *Geol. Mag.* 3, 193-6(1916).—The rock is an andesitic basalt, distinguished by containing phenocrysts of anorthite or bytownite in a ground mass composed of laths of labradorite, augite frequently intergrown with enstatite and hypersthene; and an abundant mesostasis of dark glass. The xenoliths are largely pitchstones, surrounded by a skin and sometimes clots of glass darkened by streaks and patches of dark dots, chiefly hematite, arranged with fluxional structure. From the effect of the heat on the phenocrysts of the pitchstone, the temp. of the basaltic magma during intrusion is estd. as between 1,170 and 1,375°. S. G. GORDON.

**Albite-granophyre and quartz-porphyr from Brandy Gill, Carrock Fell.** ARTHUR HOLMES. *Geol. Mag.* 4, 403-7(1917).—A petrographic description. The granophyre was analyzed by H. S. Harwood, and the analysis indicated that the Fe content was too high for glass manuf. S. G. GORDON.

**The Pahang series.** E. S. WILLBORUN. *Geol. Mag.* 4, 447-62, 503-14(1917).—The series includes rhyolite, trachyte, andesite, quartz-porphyr, granophyre, porphyrite, quartz dolerite, dolerite, and rhyolite, rhyolite-andesite, and andesite tuffs. These rocks are described, and one analysis of andesite is given. S. G. GORDON.

**The geology of Mount Remarkable, with petrographic notes on the basic igneous rocks at the foot hills of Mount Remarkable.** WALTER HOWCHIN AND E. O. THIELS. *Trans. Proc. Roy. Soc. S. Australia* 40, 545-83(1916).—The formations comprize Lower Cambrian limestones, slate, glacial tillite, quartzite and igneous rocks, and Upper Cambrian slate and quartzite. The igneous rocks occur as disconnected pipes on the southeastern side of the Mount, and include dolerite, altered basalts, acid porphyritic rocks and aplites. An analysis of quartz-keratophyre is given. S. G. GORDON.

**The chemical composition of vaugnerite and the position of this rock in the classification.** A. LACROIX. *Bull. soc. franc. min.* 40, 158-62(1917).—Two new analyses of this rock are given, and recalcd. into the mineral compn. It is found to be a monzonitic rock, and is comparable with kentallenite. The rock from a dike which cuts the body of vaugnerite has also been analyzed, and on comparison of its compn. with that of absarokite, the dike rock is found to be essentially a lamprophyric absarokite.

E. T. W.

**Preliminary notes on the lava of Volcano Sambe.** TADAO FUKUTOMI. *J. Geol. Soc. Tokyo* 25, No. 295, 10-25(1918).—The lava is a porphyritic light-colored dacitic andesite. It is described in detail with analyses of the rock and of its plagioclase, hornblende, and mica. S. G. GORDON.

**Notes on miharaite.** SEITARO TSUBOI. *J. Geol. Soc. Tokyo* 25, No. 302, 47-58 (1918).—Miharaite is the name given to an aphanitic rock found in the central cores of Oshima. The rock is composed of megaphenocrysts of calcic bytownite ( $\text{Ab}_{40}\text{An}_{60}$ ) with the  $n_s$ :  $\alpha < 1.572 < \beta < 1.578 < \gamma$ , with a few of hypersthene and clinohypersthene, in a gray percrystalline or docrystalline and decimillimeter-grained groundmass of plagioclase, augite grains, magnetite, apatite (extremely rare) and a negligible amount of glass. In slaggy parts the rocks is hyalocrystalline plagioclase and augite swimming in a brown mass. Av. of 4 analyses:  $\text{SiO}_2$  51.45,  $\text{Al}_2\text{O}_3$  16.84,  $\text{Fe}_2\text{O}_3$  1.49,  $\text{FeO}$  10.95,

MgO 4.48, CaO 10.71, Na<sub>2</sub>O 1.23, K<sub>2</sub>O 0.37, H<sub>2</sub>O 0.72, TiO<sub>2</sub> 1.27, P<sub>2</sub>O<sub>5</sub> 0.26, MnO 0.19, sum 99.96%. S. G. GORDON.

**Graphic granite.** JACQUES DE LAPPARENT. *Bull. soc. franc. min.* 40, 111-5 (1917).—Because of the resemblance in structure to certain alloys and the apparent constance of the proportion of quartz to feldspar, geologists have been inclined to regard graphic granite as an eutectic. Observations on various occurrences have led L. to discard this view. In a true eutectic any excess of either mineral would crystallize out first, whereas the graphic granite itself is always the first to solidify in pegmatite veins. The rock is, however, capable of explanation by the Soret principle, that in a homogeneous liquid, material diffuses toward a cool region. The pegmatite magma being practically a satd. soln. of quartz and feldspar, there must be a constancy, though only relative, of the constituent minerals. E. T. W.

**A new ferriferous type of crystalline schist, collobrérieite.** A. LACROIX. *Bull. soc. fran. min.* 40, 62-9 (1917).—The Fe-bearing schists at Collobrières have been previously known to contain unusual Fe silicates, and a new collection of specimens has yielded further data on these. The microscopic characters of the rock are described, and an analysis by Raoult is given, which on recalcn. yields the mineral compn.: gruen-erite 43.7, fayalite 21.1, garnet 16.6, ilmenite + magnetite + pyrite + pyrrhotite 17.5, and apatite 1.1%. The nearest previously described rock is eulysite from Tunaberg, Sweden, but the present material is different from that in origin, so the new name *collobrièreite*, after the locality, is proposed for the rock type. Considerable variation from the compn. above described occurs from one specimen to another. Siderite, apparently of secondary derivation from the fayalite, is at times abundant. Apatite and magnetite also locally increase in amount, the latter being often in peculiar porphyritic forms, and being notable for the low Ti content. E. T. W.

**The application of petrological and quantitative methods to stratigraphy.** P. G. H. BOSWELL. *Geol. Mag.* 3, 105-11, 163-9 (1916).—A discussion of the sepn. of the minerals of sediments by panning and the use of heavy liquids, and a petrographic study of those so occurring, their size, form, degree of alteration, and relative abundance. Detrital mineral assemblages are believed to be of considerable value for stratigraphical purposes over limited areas. S. G. GORDON.

**Notes on diatomaceous earth from Lord Howe Island.** WALTER HOWCHIN. *Trans. Proc. Roy. Soc. S. Australia* 41, 659-60 (1917).—The rock was washed up on the beach, and is excessively fine and remarkably uniform, with a few brown specks shown to be fish scales. A microscopic examn. showed that the earth consisted of very finely divided flocculent matter in which were imbedded great numbers of diatoms, sponge spicules and a few radiolaria. Foraminifera were absent. Analysis by W. S. Chapman gave: moisture 3.7, combined H<sub>2</sub>O and organic matter 5.7, SiO<sub>2</sub> 63.8, Al<sub>2</sub>O<sub>3</sub> 5.9, Fe oxide 3.0, CaO 2.2, MgO 7.9, alkalies not detd., sum. 92.2%. S. G. G.

**The singing sand of Koto-ga-hama, Iwami.** SEITARO TSUBOI. *J. Geol. Soc. Tokyo* 25, No. 295, 8-9 (1918).—This sand is said to utter a sweet sound when tread upon. The size of grain varies from 0.28 to 0.95 mm., and is composed almost wholly of oligoclase-andesine feldspar (Ab<sub>77</sub>An<sub>23</sub> — Ab<sub>70</sub>An<sub>30</sub>) with minor amts. of orthoclase, hornblende, hypersthene, magnetite, quartz, and shelly matter. S. G. GORDON.

**The iodine and bromine content of a sample of water from Lake Gairdner.** W. TERNENT COOKE. *Trans. Proc. Roy. Soc. S. Australia* 41, 39-40 (1917).—Analysis showed that 1 l. of lake water contained 0.0005 g. I and 0.07 g. Br. S. G. GORDON.

**Native supplies of refractory materials available in the Sheffield district.** W. G. FEARNSIDES. *Trans. Eng. Ceram. Soc.* 17, 271-92 (1918).—A general description of the deposits considered chiefly from the geologic standpoint. C. H. KERR.

Radioactivity of Italian minerals (FRANCESCONI, *et al.*) 3. The orientation of anisotropic liquids in contact with crystals (GRANDJEAN) 2. Structure of crystals in extremely thin plates (MARCELIN) 2.

## 9. METALLURGY AND METALLOGRAPHY.

WILLIAM BRADY, WILLIAM T. HALL.

Secondary metals in 1917. J. P. DUNLOP. U. S. Geol. Survey, *Mineral Resources of U. S., 1917*, Part I, 299-330 (preprint No. 15, published Feb. 19, 1919); cf. C. A. 12, 34. E. H.

The production of iron and steel in Canada during the calendar year 1917. JOHN McLEISH. Can. Dept. Mines, Mines Branch. *Adv. Chapter of the Annual Rept. on the Mineral Production of Canada during 1917*, No. 498, 32 pp.(1919); cf. C. A. 12, 1279. E. J. C.

The production of copper, gold, lead, nickel, silver, zinc, and other metals in Canada during the calendar year 1917. ARTHUR BUISSON. Can. Dept. Mines, Mines Branch. *Adv. Chapter of the Annual Rept. on Mineral Production of Canada during 1917*, No. 497, 71 pp.(1919); cf. C. A. 12, 1279. E. J. C.

Gold, silver, copper, lead and zinc in California and Oregon in 1917. CHARLES G. YALE. U. S. Geol. Survey, *Mineral Resources of U. S., 1917*, Part I, 203-52 (preprint No. 13, published Feb. 18, 1919); cf. C. A. 12, 349. E. H.

Gold, silver, copper, lead and zinc in Nevada in 1917. V. C. HEIKES. U. S. Geol. Survey, *Mineral Resources of U. S., 1917*, Part I, 253-98 (Preprint No. 14, published Feb. 18, 1919); cf. C. A. 12, 576. E. H.

Gold, silver, copper, lead and zinc in Montana in 1917. V. C. HEIKES. U. S. Geol. Survey, *Mineral Resources of U. S., 1917*, Part I, 331-66 (preprint No. 16, published Feb. 21, 1919); cf. C. A. 12, 464. E. H.

Quicksilver in 1916. H. D. MCCASKEY. U. S. Geol. Survey, *Mineral Resources of U. S., 1916*, Part I, 757-73 (preprint No. 24, published Feb. 19, 1919). E. H.

Fume and other losses in condensing quicksilver from furnace gases. L. H. DUSCHAK AND C. N. SCHUETTE. *Bur. Mines, Tech. Paper* 96, 29 pp.(1919).—The no. of *Tech. Paper* given in C. A. 13, 415, is incorrect. E. H.

Defining "tailings" and "residues." A. W. ALLEN. *Eng. Mining J.* 107, 317 (1919).—The following definitions are proposed: "*Tailing*: The material from which one or more concd. products have been removed, and which is available for further treatment. *Residue*: The waste or final product from a hydrometallurgical plant which, at the time of operation, is valueless as far as metal content is concerned."

F. W. SMITHER.

Influence of temperature upon the action of slag upon refractory materials. R. M. HOWE. *Chem. Met. Eng.* 20, 167-8(1919).—H. reports results obtained with 6 different slags and 3 standard brands of firebrick. The method of procedure is practically the same as that followed by Nesbitt and Bell (cf. C. A. 10, 2972). In each case the slag penetrated more deeply into the brick at higher temps. In several cases an

increase of 100°, or less than 10%, resulted in nearly doubling the penetration. H. concludes that "it appears very much as if the relation of output and the life of the lining is similar to the rate of driving and the life of an automobile." The lives of furnace linings should be compared according to a sliding scale. F. W. SMITHER.

**Flocculation in flotation.** C. C. SMITH AND A. R. PICKETT. *Eng. Mining J.* 107, 365-6(1919).—Discussion of a paper by G. J. Young (*C. A.* 13, 412). The authors point out that Y. has overlooked the fact that NaOH is a strong electrolyte. Acid is often beneficial in flotation, usually by the formation of a more selective froth; in many cases it is found to be detrimental to froth formation, and some ores give better results when an alk. pulp is used. The authors have made careful microscopic examn. of over 2000 mineral-bearing froths formed from a number of different ores and with a wide variety of frothing agents, and in few cases has there been noticeable any flocculation of the mineral. In practically all cases the mineral exists in the film in the form of distinct, individual particles. When sufficient oil is used to cause cohesion of the sulfide particles, granulation will result under proper conditions. Such granulation is detrimental to froth formation. Flocculation, which is incipient granulation, is detrimental to both froth formation and the recovery of the mineral; whenever mineral floccules are apparent in the pulp, any change in the conditions which tends to decrease the flocculation results in improvement in both froth formation and metal recovery. Flotation is easily explained by reference to well known physical phenomena and without the aid of hypothetical, unlikely chem. reactions. The authors describe an expt. from which they conclude that, in the presence of H<sub>2</sub>O, oxidized oil is no better and no worse as a coating agent than unoxidized oil. The persistence of adsorbed air films at the surface of submerged sulfide particles is an assumption for which no proof is offered, and the presence of such films on the surface of particles ground under H<sub>2</sub>O, as is the case with flotation feeds, is even more unlikely. F. W. SMITHER.

**Silverado flotation concentrator.** W. L. ZEIGLER. *Mining Sci. Press* 118, 329 (1919).—A description, with a drawing, of the Zeigler flotation machine installed at the Silverado mine. In this machine, air is introduced into the frothing compartment, in which is a revolving agitator. The froth is said to resemble that made in a pneumatic cell. The ore is minute stringers and grains of galena, gray Cu, and pyrite disseminated through a heavy gang of spathic Fe with quartz, all the Ag being associated with the PbS and gray Cu. The ore is treated at 40-mesh, the ratio of concn. being about 15:1. The Pb shows an extn. of 97%, the Ag 92.2%, with practically all the Cu. F. W. SMITHER.

**Flotation of oxidized ores of lead.** G. L. ALLEN. *Chem. Met. Eng.* 20, 169-75 (1919).—A. discusses the sulfidizing process and its application (cf. Ralston and Allen, *C. A.* 10, 2338). Cerussite and wulfenite sulfidize very readily; minium, anglesite, and pyromorphite slowly tarnish to a dull black in strong Na<sub>2</sub>S solns., but in practice poor recoveries are made on these materials by sulfidizing and flotation. Vanadinite and desloizite are indifferent toward Na<sub>2</sub>S; cerargyrite and AgBr sulfidize readily. Mn compds., especially pyrolusite, basic sulfates of Fe, peroxides of Pb, and Fe<sup>++</sup> salts in soln. interfere with the process. A. describes in detail, with flow sheet, tables of results, etc., mill tests made on the oxidized Pb ore of the Shattuck-Arizona Copper Co., at Bisbee, Ariz. Cerussite, cerargyrite and Au are the valuable minerals; the av. daily chem. analysis of the ore was: Au, 0.054 oz. per ton; Ag, 5.86 oz. per ton; Pb, 11.39; insol., 64.12; Fe, 12.8%. The oils used in flotation were for the most part mixts. of hardwood and coal creosotes with small amts. of pine or pine-tar oils in addition. F. W. SMITHER.

**Fine crushing in ball-mills.** E. W. DAVIS. *Bull. Am. Inst. Mining Eng.* 1919, 111-56.—A detailed account, with tables of results, flow sheet, formulas, curves, etc.

of tests carried out on siliceous rock (about 35%  $\text{Fe}_2\text{O}_3$ , remainder chiefly quartzite and Fe silicates) in an exptl. plant at Duluth, Minn. The matter is presented under the general captions: (1) Operating tests; (2) mechanics of the ball-mill; (3) ball wear; (4) practical application of theoretical conclusions. Largely mathematical.

F. W. SMITHER.

**Milling calculations.** R. S. LEWIS. *Chem. Met. Eng.* 20, 224-33 (1919).—A compilation of formulas useful in detg. extn. of processes, efficiency of machines, d. of solids, solns., and pulps, together with notes on methods of testing and microscopic examn. A bibliography on milling calcns. is appended.

F. W. SMITHER.

**Problems involved in the concentration and utilization of domestic low-grade manganese ore.** E. NEWTON. U. S. Bur. Mines, *War Minerals Inves. Series* 1918, No. 9, 20 pp.; *Bull. Am. Inst. Mining Eng.* 1919, 379-89.—A review and discussion under the general captions: (1) Introduction; (2) Mn deposits in the U. S.; (3) metallurgical requirements of the steel industry; (4) concn. of domestic low-grade Mn ores; (5) factors controlling the possibilities of concn. The author gives estimated cost data applied to 3 Calif. ores.

F. W. SMITHER.

**First year of leaching by the New Cornelia Copper Co.** H. A. TOBELMANN AND J. A. PORTER. *Bull. Am. Inst. Mining Eng.* 1919, 449-95.—A detailed report, with illustrations, tables, flow sheet, discussion, etc., of the operation from May 1, 1917, to May 1, 1918, of a plant at Ajo, Ariz. The ore carried a total Cu content of 1.63%. The process adopted was as follows: (1) mining by steam shovels; (2) crushing to  $\frac{1}{4}$  in.; (3) leaching the crushed ore 8 days by a countercurrent system and upward circulation, using  $\text{H}_2\text{SO}_4$  and such  $\text{Fe}_2(\text{SO}_4)_3$  as is inherent in the process; (4) reduction by  $\text{SO}_2$  gas of the  $\text{Fe}^{+++}$  remaining in the neutral solns. from the leaching tanks; (5) the electrodeposition of part of the Cu from this reduced soln., which is then returned to the leaching soln.; (6) the continuous discharge of such portion of the neutral soln. as is necessary to prevent accumulation of sulfates, other than Cu, to the satn. point; (7) the recovery of the Cu content of such discarded soln. as cement Cu pptd. on Fe; (8) the treatment of a part of this cement Cu with soln. from the electrolytic tank house to the end that the Cu be returned to the circulation and a part of the  $\text{Fe}_2(\text{SO}_4)_3$  be reduced. Cf. C. A. 10, 2682.

**Basic refractories for the open-hearth.** J. SPOTTS McDOWELL AND RAYMOND M. HOWE. *Bull. Am. Inst. Mining Eng.* 1919, 291-309.—The 6 materials studied include 2 magnesites, 2 dolomites, and 2 specially treated dolomites, which may be designated, respectively, by the letters A, B, C, D, E, and F. Material A was prepd. from Washington magnesite, ground with  $\text{Fe}_2\text{O}_3$ , and dead-burned. B is a similar product prepd. from Canadian magnesite. C is a prepn. made by coating dolomite granules at high temps. with basic open-hearth slag. D is made by mixing  $\text{Fe}_2\text{O}_3$  and dolomite and calcining at a high temp. E is a relatively impure dolomite that has been calcined. F is a rather pure calcined dolomite. Lab. tests were devised which would to some extent be a measure of the behavior of the different materials in actual practice. The magnesite that was the lower in lime showed less tendency to slake and higher refractoriness, as well as a greater resistance to attack by firebrick and silica brick, and to the action of a corrosive  $\text{Fe}_3\text{P-Fe}_2\text{O}_3$  mixt. than did the high-lime magnesite. With reference to the dolomitic materials, the purest dolomite in general showed the poorest resistance to corrosion, while the materials highest in impurities and lowest in CaO were most resistant to slaking. The magnesites are more resistant than the dolomites or dolomitic preps. to slaking, to the action of the  $\text{Fe}_3\text{P-Fe}_2\text{O}_3$  mixt., of fireclay, and silica. Considering these tests only, the value for refractory purposes of the materials studied may be placed in the same relative order as that first enumerated above.

A. L. FRID.

**Use of manganese alloys in open-hearth practice.** SAMUEL L. HOYT. *Bull. Am. Inst. Mining Eng.* 1919, 279-89.—A presentation of the work done by the War Minerals Investigation, Manganese Section, of the Bureau of Mines, on the use of Mn alloys in open-hearth practice. In the U. S., Mn occurs largely as a low-grade mixt. with Fe and  $\text{SiO}_2$  or with both. The investigation was carried on to det. the extent to which low-grade Mn alloys could properly be substituted for high-grade alloys without materially impairing the quality or quantity of steel produced. As a result of the investigation it is advanced that there are three practices for utilizing our domestic alloys in open-hearth work that commend themselves. They are (1) the use of a molten mixt. of spiegel and pig iron for deoxidation and recarburization, (2) the practice of melting and refining the steel bath so as to secure a comparatively high residual Mn content, about 0.30% Mn, and (3) the use of Mn alloys containing Si. Each of these procedures has been practiced recently at certain plants. With regard to (1), the spiegel mixt. contains from 5 to 11% Mn, 4% C, and the desired amt. of Si, and is added to the ladle during the tapping time in such a way as to get a thorough mixt. of the 2 streams. The advantages of this practice are limited practically to the manuf. of steels running 0.30% C or above. At certain plants a practice of preferential oxidation of C and P has been developed by which the residual Mn is kept comparatively high, about 0.25-0.30%, as compared with 0.10% Mn, for a final C content of 0.10%. The high Mn content of the charge is generally secured by using a high-Mn pig iron, 2 or 3% Mn. The loss of Mn is considerable and would appear to be unavoidable. Data for one heat showed a recovery of 32.6%. In this practice, however, it is possible to use domestic manganiferous iron ore to produce the high-Mn pig, and, assuming the finished steel contains above 0.10% C, to use spiegel at the end of the heat. This practice has certain disadvantages, however, one being that the C content of the bath has to be worked to a lower value than in present practice. Other disadvantages are the high cost of spiegel and the greater time required. The use of Mn-Si alloys will find their first application in the production of forging steel, high-carbon steels and castings where the aim is to produce sound steel and where Si can be used up to 0.20 to 0.35%. The relative merits of the addition of the single alloy as against the addition of ferromanganese plus ferrosilicon can hardly be passed on from the data available. The paper also contains a discussion of the function of Mn in the deoxidation process. It is concluded that in so far as is known it would be impossible to secure a satisfactory substitute, abundant in this country, which would perform all of the functions of Mn.

A. L. FEILD.

**Water-cooled equipment for open-hearth furnaces.** WM. C. COFFIN. *Bull. Am. Inst. Mining Eng.* 1919, 497-515.—A description of modern methods of protecting the refractory linings of open-hearth furnaces by means of water-cooled equipment. Numerous drawings of different applications are given. Decided advantages are claimed for properly designed welded steel plates as material for the construction of practically all shapes used.

A. L. FEILD.

**The deoxidation of steel by ferromanganese.** A. L. FEILD. *J. Ind. Eng. Chem.* 11, 242-4(1919).—The work of previous investigators is cited to show that our present knowledge regarding the true function of ferromanganese, ferrosilicon, and the other deoxidizers is insufficient to explain the observed facts. It is predicted that this problem will be solved only by more extensive measurements of equilibria at high temps. and by the accumulation of a more adequate supply of data concerning the sp. hts. and stability relations of the elements and compds. concerned.

A. L. F.

**The Mondeville-Colombelles Iron and Steel Works.** ANON. *Engineering* 107, 136-7(1919).—A detailed description, with illustrations, of the works near Caen, France. The expected output for the present year is given.

F. W. SMITH.

**Static, dynamic and notch toughness.** SAMUEL L. HOYT. *Bull. Am. Inst. Mining Eng.* 1919, 339-51.—The point of view presented in this paper is that toughness, like hardness, or tensile strength, should be regarded as an independent property of sufficient importance to require quantitative measurement and to be included in specifications. A stress applied to a bar that has a sudden change in cross section, as at a nick or groove (a *notch*), produces a decidedly non-uniform strain distribution at the change of cross-section. This non-uniform strain distribution is referred to as the *notch effect*. Material that is used in the notched condition cannot be differentiated as to whether it is likely to stand up or fail by the tests for toughness which are usually applied. The recognition of the peculiar weakness of certain materials in the notched condition has lead to the development of the impact test on notched bars as a supplement to the usual static and dynamic tests. Even a hasty examination of such machines as locomotives, automobiles, gas engines, etc., reveals an amazingly large no. of notches and materials used in their construction should have a high degree of notch toughness to insure against failure. Microscopic examination on materials, such as splice bars, rear axles and truck steering arms, shows that the trouble was due often to the notch effect. Also in *Iron Age* 103, 545(1919). W. T. H.

**Shimer case-hardening process.** JOSEPH W. RICHARDS. *Bull. Am. Inst. Mining Eng.* 1919, 431-3.—P. W. Shimer has invented a substitute for the bath of melted cyanides which case-hardens with equal or greater facility, gives off no poisonous vapors and costs less. The Shimer liquid bath is obtained by adding fresh  $\text{CaCN}_2$  to a mixt. of easily fusible salts, such as may be obtained by mixing  $\text{NaCl}$ ,  $\text{CaCl}_2$  and  $\text{BaCl}_2$  in equal amts. The method of preparing the bath is explained in detail. W. T. H.

**Effect of temperature, deformation and grain size on the mechanical properties of metals.** ZAY JEFFRIES. *Bull. Am. Inst. Mining Eng.* 1919, 575-8.—The summary is given of a thesis submitted to Harvard Univ. Cf. *C. A.* 13, 220. W. T. H.

**Microstructural features of flaky steel.** HENRY S. RAWDON. *Bull. Am. Inst. Mining Eng.* 1919, 183-201.—In the manuf. of steel defects often occur which are popularly termed "snow flakes," "flakes" or "scabs." These flakes are not usually found in the plain steels but are very common in steel containing Ni or Cr and Ni. The characteristic macro- and micro-structure of flaky steel is described and the conditions are explained under which such defects may be produced. The coarse crystals have the appearance suggesting plastic bodies which have been squeezed together and failed to adhere. The defects originate, probably, in the ingot where they have the appearance of intercryst. shrinkage cracks. They occur in the cast metal along with slag inclusions in the angles between the branches of the dendritic crystals. They persist throughout the history of the forging into the finished form as discontinuities in the metal, often associated with slag films which have resulted from the working down of slag inclusions. Though they are usually associated with dirty steel, they are not always present in such steel. W. T. H.

**Prevention of columnar crystallization by rotation during solidification.** HENRY M. HOWE AND E. C. GROESBECK. *Bull. Am. Inst. Mining Eng.* 1919, 361-5.—Continuously varying rotation during solidification keeps the metal sweeping past the walls where it is solidifying. Tchernoff, before 1880, proposed such treatment of ingots solidifying in a mold and Webb cast locomotive driving wheels in this manner. Rxpts. with a hot soln. of ammonium alum resulted in larger crystals being formed with quiescent solidification than with rotating solidification and similarly, with a mixt. of Zn and 5% type metal, columnar crystals were obtained to a greater degree when the molten metal was allowed to cool quietly than when the mold was rotated. W. T. H.

**Flaky and woody fractures in nickel steel gun forgings.** CHARLES Y. CLAYTON, FRANCIS B. FOLLY AND FRANCIS B. LANEY. *Bull. Am. Inst. Mining Eng.* 1919, 203-37.—The most characteristic feature of flaky steel under the microscope is the lack of complete grain refinement. The woody texture and flakes appear more prominently when the steel is broken in a direction transverse to that of elongation in forging. When flakes appear there is usually evidence of overheating, such as shown by Widmannstättian structure in the sorbite grains and the so-called *spiny* ferrite bands. The microscopic appearance indicates that the flakes are caused by the rupture of small areas irregularly distributed through the metal so differing from the other metal that the rupture occurs both in the ferrite and through the sorbite in the Widmannstättian plates. Probably some non-ferrous metal is segregated in the ferrite, thus making it more brittle than the surrounding metal. Chem. tests indicate that the flake areas are higher in P and C than the normal metal. When flakes are present small cracks develop at right angles to the direction of stress in the tensile test. The bars show loss of ductility and somewhat lessened strength. As regards the woody fracture, it is probably caused by the condition of the steel with respect to the original dendritic structure. By working the original dendrites in parallel lines by forging a laminated or woody fiber is produced. The greater the amt. of work applied, the longer and thinner do these longitudinal lines become and there results a low transverse ductility. When transverse strains are to be withstood, care should be taken not to subject a Ni-steel to much hot work.

W. T. H.

**Davidson process of casting formed tools.** J. E. JOHNSON, JR. *Bull. Am. Inst. Mining Eng.* 1919, 353-60.

W. T. H.

**Effect of cold working and rest on the resistance of steel to fatigue under reversed stress.** H. F. MOORE AND W. J. PUTNAM. *Bull. Am. Inst. Mining Eng.* 1919, 391-404.—It has been known for some time that the elastic limit, the yield point and the ultimate strength of steel may be raised by cold working if a period of rest ensues after the cold work. There are but few test data on the fatigue strength of cold-worked steel under repeated stresses and tests here described were undertaken to det. whether increased fatigue strength accompanied increased dead-load or static strength due to cold-working of steel. The tests, which are described at length and summarized in plots and tables, indicate than an increase in the strength of medium-C steel due to cold working does not necessarily indicate increased resistance to fatigue under repeated stress. No marked benefit of a short period of rest on the fatigue strength could be detected.

W. T. H.

**Molybdenum-steel vs. gun erosion.** MASATOSI ÔKÔCHI, MASAICHI MAJIMA AND NAOSHI SATO. *J. Coll. Eng. Tokyo Imp. Univ.* 9, 153-95(1918).—An investigation of the physical properties of Mo steel and other special steels used for gun barrels, *vis.*, ordinary gun steel, Ni-steel, Ni-Mo-steel, and W-steel. *Modulus of elasticity:* Av. value of  $E$  for 7 different samples of Mo-steel (containing from 0.32 to 1.58% Mo) was 22,178 kg./mm<sup>2</sup>., about 1.4% greater than that found for ordinary gun steel. *Modulus of rigidity:*  $R$ , modulus of rigidity, for Mo-steel containing 1.05% Mo is equal to 8,670 kg./mm<sup>2</sup>., from which, with value of  $E$ , Poisson's const. is calcd. to be 0.275. *Hardness:* This was measured with the Brinell machine on unquenched specimens and on specimens quenched at various temp. up to 900°. A rapid increase of hardness was observed in range 600-750°. No effect was noticed below 600°. Specimens annealed at 900°, slowly cooled to a lower temp., and then quenched, showed an increase in hardness at much lower temps. than those quenched in the ordinary way. The same hardness, therefore, is obtained with less stress due to temp. differences, if the steel is quenched at  $\gamma$  state whatever its temp. may be. *Thermal dilatation:* A contraction, due to the change from the  $\alpha$  to  $\gamma$  state, occurs in Mo, W, and gun steel at about 750°.

while in Ni and Ni-Mo steel it appears at about  $700^{\circ}$  or slightly lower, and in both cases continues over a range of from  $30$  to  $80^{\circ}$ , after which expansion again takes place. The rate of expansion in the  $\gamma$  state is more rapid than that in the  $\alpha$  state, so that the coeff. of expansion for the latter lies between  $1.0 \times 10^{-6}$  and  $1.7 \times 10^{-6}$ , while for the former it is between  $2.0 \times 10^{-6}$  to  $2.2 \times 10^{-6}$ . By gradually cooling the specimen after the  $\gamma$  state is reached, it contracts as the temp. decreases, but a sudden expansion is observed at the  $A_1$  transformation. The temp. difference between  $A_c$  and  $A_r$  transformations is in the case of Mo-steel equal to  $47^{\circ}$ , and to  $320^{\circ}$  for Ni-Mo steel. The expansion of quenched specimens was also studied. *Thermal conductivity:* For Mo-steels, the value of  $k$ , in g. cal./cm<sup>2</sup>., varies for a temp. of  $50^{\circ}$  between  $0.081$  and  $0.129$ , depending upon the compn. For ordinary gun-steel,  $k = 0.127$ . *Conclusions:* The data obtained are not sufficient to det. whether Mo steel is preferable as gun material or not. When compared with W- and Ni-steels it produces a steel of higher thermal cond., about equal to that of C steel. Low thermal cond. may be one of the reasons Ni steel is more easily eroded than C steel. There is no satisfactory theory for the formation of numerous fine cracks on the surface of a gun bore when many rounds have been fired. Since the surface is heated by firing to a temp. higher than the  $A_1$  transformation, and since a sudden contraction will be produced on the surface at the critical temp. while the other part of the wall continues to expand continuously, the rupture of the thin layer may be expected if the shearing and tensile stresses on the thin layer and the circumferential stress due to the internal pressure produced by combustion are much greater than the temp. stress where the inner surface is hotter than the external and consequently subjected to compressive stress. If the above is true, the coeff. of contraction of the material at  $A_1$  transformation must be one of the most important factors in erosion. This is in accord with the observation that erosion increases with the C content, since it has been observed by Honda that the mean coeff. of contraction at the critical temp. increases with the carbon content of the steel.

A. L. FIELD.

**Magnetic properties of iron alloys.** GUMMICH. *Elektrotechnik und Maschinenbau* Sept. 1, 1918; *J. Ind. Eng. Chem.* 11, 247(1919).—The materials used in the investigation consisted of pure electrolytic Fe and four series of alloys with increasing C content (up to 1.8%). The d. and sp. resistance vary with the percentage of added material. It would seem that the addition of Si or Al does not improve to any extent the magnetic properties of Fe, and any benefit derived by their presence is due to secondary causes as O is removed and the effect of the C is somewhat neutralized. Eddy-current losses are reduced by the addition of Si and Al. Results are also given showing the effect of the added materials on the coercive force and from them it would appear that good permanent magnets can be produced by adding W, Cr or Mo to Fe.

E. J. C.

**Path of rupture in steel fusion welds.** S. W. MILLER. *Bull. Am. Inst. Mining Eng.* 1919, 311-38; cf. *C. A.* 12, 671.—The existence of needles or plates (possibly of Fe nitride) at the grain boundaries in welds suggests that these may be the cause of brittleness in electric welds. Recently similar needles have been discovered in oxy-acetylene welds. In this case, however, they have not been found in the body of the welds and have not had any noticeable effect upon the strength of the weld. Heavy oxy-acetylene welds are, however, often very brittle. A small testing machine was made in which a specimen could be bent, after being polished and etched, and examined under the microscope. The results obtained are best understood by inspection of the 82 photomicrographs which are reproduced. The first evidence of strain in any weld takes place wherever there are visible defects in the weld, such as are caused by films of oxide around the grains of metal. The structure is usually more columnar in electric

welds than in gas welds. Probably the slower rate of cooling of gas welds makes the grains more nearly equiaxed. Metals like Mn, or V, which tend to preserve the pearlitic structure in a gas weld, seem to produce more columnar grains. If there are no defects in the welds, the first appearance of distortion varies with the kind of weld and kind of material used. In oxy-acetylene welds made with pure Fe without Mn or V, slip bands appear in the grains first. In all elec. welds and in gas welds with material containing considerable C and especially if Mn or V are present sufficient to preserve a pearlitic structure, the path of rupture is along the grain boundaries. In all brittle welds, the structure is more or less columnar. They all contain pearlite, cementite or possibly Fe nitride or oxide. To account for the brittleness of any weld, it seems necessary to assume that it is caused by films of material at the grain boundaries. W. T. H.

**Manganese bronze.** P. E. MCKINNEY. *Bull. Am. Inst. Mining Eng.* 1919, 421-5. —In marine construction, mining machinery, etc., where corrosion is likely to be a serious problem, Mn-bronze has been much used. The purpose of this paper is to suggest possibilities with regard to the more economical manufacture of this alloy. Results of about 3 yrs. of operation have shown that it is not necessary to use strictly high grade virgin materials to obtain a good bronze. W. T. H.

**Volatilization of cuprous chloride on melting copper containing chlorine.** S. SKOWRONSKI AND K. W. MCCOMAS. *Bull. Am. Inst. Mining Eng.* 1919, 169-79. —Expts. in which Cu containing Cl was melted under CO<sub>2</sub>, under air and under furnace gases prove that under present Cu refining practice any Cu<sub>2</sub>Cl<sub>2</sub> present in or on the cathode can be regarded as completely volatilized on melting. This may result in serious metallurgical loss of Cu. W. T. H.

**Refining nickel-copper mat.** C. LANGER and O. LANGER. U. S. 1,291,030, Jan. 14. Roasted Ni-Cu mat is treated with dil. H<sub>2</sub>SO<sub>4</sub> to dissolve out the greater proportion of the Cu oxide and the residue is then treated with strong H<sub>2</sub>SO<sub>4</sub> at a temp. of about 150° to convert oxides into sulfates, the latter are dissolved in H<sub>2</sub>O and the Cu is pptd. by use of finely divided metallic Ni. Cf. C. A. 12, 37.

**Vertical zinc smelting furnace.** F. FIECHTL. U. S. 1,291,643, Jan. 14.

**Reclaiming metal scrap.** E. R. SUTCLIFFE. U. S. 1,291,672, Jan. 14. Metal scrap (such as shavings, borings, turnings, sawdust or the like) is intimately mixed while wet with a flux such as borax, soda or potash, so that the particles are subjected to a rubbing action and are covered with a layer of the flux, and the material is then briquetted under heavy pressure to prep. it for melting.

**Iron and steel manufacture.** ARMSTRONG, W. G. WHITWORTH & Co., F. B. TREVELYAN and W. C. ROWDEN. Brit. 121,785, Dec. 29, 1917. In the production of steel from scrap, with or without pig Fe, the C necessary to enable the charge to boil in the required manner without burning is introduced into the open-hearth or other furnace used in a dense or difficultly combustible form, such as charcoal briquets. Ore may be added to the charge if necessary.

**Hardening iron or steel.** J. W. BOYD. Holl. 2,643, Oct. 15, 1918. Fe is placed, cold, in molten KCN contg. powdered C in suspension, and the bath is heated to the desired temp. The metal is then plunged into a suitable liquid to cool.

**Manganese steel.** W. G. NICHOLS. U. S. 1,291,655, Jan. 14. Mn steel is prepd. by sepg. slag from blown metal, weighing the metal while it is still at a temp. of about 1650° and then adding to it a sufficient quantity of a 20% Mn steel alloy at a temp. of about 1300° to produce a steel having a content of 11-14% Mn and of proper temp. for pouring, and then pouring the metal into molds.

**Manganese steel.** W. G. NICHOLS. U. S. 1,291,656, Jan. 14. In recovering Mn steel from scrap, the metal is heated throughout the mass under treatment to a temp. below the oxidizing point of Mn (preferably below 370°), the temp. of the bath is gradually increased to about 650° and thereafter to above 1300°, the several stages of temp. being developed throughout the bath without materially increasing the temp. of any portion of the material above that of the surrounding material. The bath is maintained at about the m. p. until the metal is needed and the temp. is then increased to render the metal more highly fluid immediately preceding the tapping of the metal, additional Mn is added, and the metal is then tapped.

**Mending fissures in castings.** W. F. SINGER. U. S. 1,291,207, Jan. 14. A compn. for closing fissures in metal castings is formed by mixing molten S with two-thirds its weight of graphite.

**Iron alloy.** J. R. SPEER. U. S. 1,291,220, Jan. 14. An alloy which is readily annealed and strengthened by heat treatment and which is adapted for making chilled roll castings is formed by fusing together approx. equal amts. of charcoal Fe and low-C steel, together with Cr 0.5-2% and Ni 0.25-1%, and casting into the desired shape.

**Magnetizable alloy.** L. W. CHUBB. U. S. 1,291,408, Jan. 14. A magnetizable alloy, suitable for use in making parts of elec. app. for use with inductions of 16,000 gausses or greater, is formed of Fe 97-98% and Ni 3-2%. The alloy has a much greater magnetic permeability than ordinary Fe or steel.

**Acid-proof alloys.** C. ROSSI. Brit. 121,730, Dec. 13, 1918. Acid-proof alloys of Fe and Si contg. not less than 13-15% or 20-21% of Si are made in a substantially pure state preferably in an elec. furnace. Pig Fe may be melted with ferrosilicon and the impurities allowed to crystallize out of the molten mass, and a small amt. of a flux such as FeS may be added; or Fe or steel scrap may be melted with ferrosilicon, Fe<sub>2</sub>O<sub>3</sub> being added when necessary to remove the C. The alloys may be used for making vessels for chem. manufs., and as anodes in electrolytic processes.

**Cleaning metal and protecting it from rust.** H. E. FINLAY and F. L. FANGBONER. U. S. 1,290,952, Jan. 14. Articles of metal which are to be cleaned and protected from rust are pickled with a hot soln. of HCl and HNO<sub>3</sub>, then immersed in a cold KCN soln. of 30° Bé., washed in Na<sub>2</sub>CO<sub>3</sub> and immersed in oil heated to above 100°.

**"Rust-proofing" iron and steel.** W. H. ALLEN. U. S. 1,291,352, Jan. 14. A soln. for rendering Fe and steel resistant to rust is formed of H<sub>2</sub>O 100, H<sub>3</sub>PO<sub>4</sub> 0.5, MnO<sub>2</sub> 0.4, and Zn 0.004-0.04 part. Any oxidizing salt may replace MnO<sub>2</sub>.

CHAS. A. ROUILLER.

Action of acylamino acid chlorides on sodiomalonic ester. V. S. GABRIEL AND BRUNO LOWENBERG. Univ. Berlin. Ber. 51, 1493-500(1918); cf. Immendorfer, C. A. 9, 1913.—*Dimethyl o-phthalimidobenzoymalonate* (a), C<sub>6</sub>H<sub>4</sub>(CO)<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>COCH(CO<sub>2</sub>Me)<sub>2</sub>, unlike the esters C<sub>6</sub>H<sub>4</sub>(CO)<sub>2</sub>NCR<sub>2</sub>COCH(CO<sub>2</sub>Me)<sub>2</sub> studied in the previous papers and from which it differs in structure only in having an *o*-C<sub>6</sub>H<sub>4</sub> instead of the CR<sub>2</sub> grouping, is not rearranged but is decompd. by NaORt; does not react

with Na in the expected way (formation of a 6-ring compd.,  $\text{MeO}_2\text{CC}_6\text{H}_4\text{CO-N.CO.CH}(\text{CO}_2\text{Me}).\text{CO.C}_6\text{H}_4$ ); and its Na salt with MeI gives an *O*- instead of a *C*-Me

deriv. *o*-Phthalimidobenzoyl chloride, from the acid and  $\text{PCl}_5$  heated until liquefied and freed from  $\text{POCl}_3$  *in vacuo* at  $100^\circ$ , columns from  $\text{C}_6\text{H}_6$ , m.  $152-3^\circ$ ; 28.5 g. in 90 cc. of hot  $\text{C}_6\text{H}_6$  are added to a soln. of 4.6 g. Na powder and 37 cc.  $\text{CH}_3(\text{CO}_2\text{Me})_2$  in 200 cc.  $\text{C}_6\text{H}_6$ ; after several hrs. the resulting Na salt is filtered off, dissolved and pptd. with  $\text{CO}_2$ , giving 12 g. (a), and HCl ppts. a further 7 g. of less pure (a); the first crop deposits from 45 cc.  $\text{Me}_2\text{CO}$  7 g. of pure (a), short, flat prisms, m.  $159-61^\circ$ , gives a cherry-red color with alc.  $\text{FeCl}_3$ . Boiled 0.5 hr. with HI, (a) gives MeI,  $\text{CO}_2$  and *o*-aminoacetophenone hydriodide, decomp.  $150^\circ$ . If 2 g. (a) in 15 cc. MeOH are treated with 3 cc. of 4% NaOMe the resulting yellow soln. soon deposits delicate yellowish white needles of the sodium salt, sol. in  $\text{H}_2\text{O}$  with neutral reaction, which when allowed to stand under the mother liquors several hrs. or more quickly when warmed form a colorless soln.; this when evapd. to dryness on the  $\text{H}_2\text{O}$  bath leaves a resinous residue, about 0.5 g. of which remains undissolved when rubbed with 100 cc.  $\text{H}_2\text{O}$  and consists of methyl *o*-phthalimidobenzoate, rhombohedrons from much MeOH, m.  $160-2^\circ$ , insol. in acids and alkalis, also obtained by warming 2 g.  $\text{C}_6\text{H}_4(\text{CO})_2\text{NC}_6\text{H}_4\text{COCl}$  with 5 cc. MeOH and 4.5 cc. of 4% NaOMe. The  $\text{H}_2\text{O}$ -sol. portion of the product seps. from a little MeOH in flat leaves, m.  $145-6^\circ$ , sol. in alkalis, repptd. by acids, gives no red color with  $\text{FeCl}_3$ ; it is monomethyl phthaloylanthrinate,  $\text{HO}_2\text{CC}_6\text{H}_4\text{CONHC}_6\text{H}_4\text{CO}_2\text{Me}$ , also obtained by cautiously fusing  $\text{C}_6\text{H}_4(\text{CO})_2\text{O}$  with  $\text{H}_2\text{NC}_6\text{H}_4\text{CO}_2\text{Me}$  and crystg. from MeOH. The Na salt of (a) heated 1 hr. at  $100^\circ$  with MeI in  $\text{Me}_2\text{CO}$  gives the compound  $\text{C}_6\text{H}_4(\text{CO})_2\text{NC}_6\text{H}_4\text{C}(\text{OMe})\text{:C}(\text{CO}_2\text{Et})_2$ , flat columns and rhombohedrons from MeOH, m.  $148-9^\circ$ , gives no red color with  $\text{FeCl}_3$ ; boiled several hrs. with HCl or HBr it gives  $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_2$  and  $\text{H}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ , whereas when heated with HI with addition of PhI from time to time to destroy the brown color of liberated I it finally yields an almost colorless soln. which is gently boiled 2 hrs. more; MeI and  $\text{CO}_2$  are evolved, the HI is distd. off *in vacuo* and the residue is crystd. from  $\text{H}_2\text{O}$  and 50% AcOH; it seps. in flat needles and 6-sided tables (1.2 g.), m.  $248^\circ$  (decompn.), sol. in alkalis, repptd. by acids, titrates as a diacidic acid with litmus, forms a light blue copper salt,  $\text{C}_{17}\text{H}_{11}\text{O}_4\text{NCu}$ ; it is probably  $\text{HO}_2\text{CC}_6\text{H}_4\text{CH}(\text{CO}_2\text{H}).\text{CO.C}_6\text{H}_4\text{NH}$  (b),

for when heated 3 hrs. with fuming HCl at  $180^\circ$  it gives  $\text{CO}_2$ ,  $\text{PhNH}_2$  and  $\text{C}_6\text{H}_4\text{CO.O.CHCH}_2\text{CO}_2\text{H}$ , m.  $151^\circ$ . Diethyl *o*-phthalimidobenzoylmalonate, prisms,

sinters  $94^\circ$ , m.  $105-7^\circ$ , gives a cherry-red color with  $\text{FeCl}_3$ , converted by HI into  $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_2$  and *o*- $\text{H}_2\text{NC}_6\text{H}_4\text{Ac}$  and by NaOMe into ethyl phthalimidobenzoate, prisms, m.  $108-9^\circ$ . Ethyl phthaloylanthrinate, broad needles, m.  $114-6^\circ$ , sol. in alkalis. Diethyl [o-phthalimidobenzoyl]ethylmalonate,  $\text{C}_6\text{H}_4(\text{CO})_2\text{NC}_6\text{H}_4\text{C}(\text{OEt})\text{:C}(\text{CO}_2\text{Et})_2$ , columns, m.  $89-90^\circ$ . Diethyl [o-phthalimidobenzoyl]methylmalonate, short, rhombohedral prisms, m.  $104-6^\circ$ , converted into (b) by HI.

CHAS. A. ROUILLER.

Some quinoline derivatives. S. GABRIEL. Univ. Berlin. Ber. 51, 1500-15 (1918); cf. preceding abstr.—Ethyl [o-phthalimidobenzoyl]cyanacetate (a), obtained in 68% yield by treating 11 g.  $\text{NCCH}_2\text{CO}_2\text{Et}$  in 60 cc.  $\text{C}_6\text{H}_6$  with 1.6 g. Na, shaking after 3 hrs. with 9.3 g.  $\text{C}_6\text{H}_4(\text{CO})_2\text{NC}_6\text{H}_4\text{COCl}$  in 30 cc.  $\text{C}_6\text{H}_6$  for 0.5 hr., letting stand overnight, shaking with much  $\text{H}_2\text{O}$  and pptg. from the aq. layer with HCl, seps. from alc. in flat needles, m.  $178-9^\circ$ , gives a brown-red color with alc.  $\text{FeCl}_3$ , sol. in  $\text{NH}_4\text{OH}$ , alkalis and carbonates; ammonium salt, yellow prisms; the silver salt,  $\text{C}_{20}\text{H}_{14}\text{O}_4\text{N}_2\text{Ag}$ , shaken in  $\text{Me}_2\text{CO}$  suspension at  $100^\circ$  1.5 hrs. with MeI, gives a methyl derivative,  $\text{C}_{22}\text{H}_{16}\text{O}_4\text{N}_2$ , columns or cryst. granules from alc., m.  $173-4^\circ$ , gives no color with alc.  $\text{FeCl}_3$ ; it is probably the *O*-Me compd.,  $\text{C}_6\text{H}_4(\text{CO})_2\text{NC}_6\text{H}_4\text{C}(\text{OMe})\text{:C}(\text{CN})\text{CO}_2\text{Et}$ ,

for with boiling HI it yields the same product  $C_8H_6ON_2$  (See (d) below) as is obtained from (a) itself. (a) dissolves in 1 mol. cold *N* alkali with neutral reaction; if a 2nd mol. of alkali is added the soln. becomes neutral slowly in the cold, rapidly on warming and HCl now ppts. an acid,  $HO_2CC_6H_4NHC_6H_4COCH(CN)CO_2Et$ , short microprisms or crusts from alc., sinters above  $255^\circ$ , m.  $263-5^\circ$  (decompn.), titrates as a dibasic acid, gives a cherry-red color with  $FeCl_3$ ; *disilver salt*. If the acid is quickly dissolved in 10 parts hot AcOH, the yellow soln. soon deposits, even while still hot, needles of *2-cyano-2,4-dihydroxyquinoline* (b),  $C_8H_4N:C(OH).C(CN):COH$ , sinters about  $170^\circ$ ,

m. about  $300^\circ$ , gives a red-yellow color with alc.  $FeCl_3$ , sol. in  $NH_4OH$ , alkalies and carbonates, titrates as a monobasic acid, converted by boiling 1 hr. with 8 parts HI and a little  $PH_4I$  into *2,4-dihydroxyquinoline*. *Silver salt*: Boiled 1.5 hrs. with 14 g.  $PCl_5$  and 30 cc.  $POCl_3$ , 6 g. (b) gives 6.5-7.0 g. *3-Cyano-2,4-dichloroquinoline* (c), needles from alc., m.  $168-9^\circ$ ; if the boiling is continued only 0.5 hr., the product, after removal of the  $POCl_3$  in *vacuo*, yields to KOH *3-cyano-2(or 4)-hydroxy-4(or 2)-chloroquinoline*, yellowish, flat needles from AcOH, does not m.  $280^\circ$ , sol. in dil. KOH, seps. as the yellowish K salt from more concd. KOH. When 3 g. (c) is boiled 6 hrs. with 1.5 g. red P and 24 cc. HI (b.  $127^\circ$ ) it gives 1.2 g. *4-hydroxyquinoline-3-carboxylic* (kynurenic) acid, m.  $265^\circ$  (decompn.). From 8 g. (a) boiled 0.5 hr. with 32 cc. HI is obtained 12 g. crystals which, when gently warmed with 100 cc.  $H_2O$ , leaves undissolved 1.5 g.  $C_6H_4(CO_2H)_2$ , while the soln., treated with a slight excess of soda and concd., yields *2-amino-4-hydroxyquinoline* (d), long needles with 1 mol. solvent from  $H_2O$ , anhydrous rhombohedrons from alc., sinters about  $285^\circ$ , m.  $303-4^\circ$ , easily sol. in HCl and in caustic alkalies, forms a cryst. chloroplatinate and chloroaurate; *hydrobromide*, hair-like needles. The mother liquors yield some *2,4-dihydroxyquinoline* (e). The same decompn. of (a) is effected, although more slowly, with boiling HBr instead of HI; in this case (e) is formed in somewhat larger amt. (e) can be obtained in 90% yield much more easily and quickly from *o*- $O_2NC_6H_4COCH(CO_2Et)_2$  (f) with HI than with Sn and HCl (Bischoff, *Beilstein*, IV, 286); 45 g. (f) are added in small portions to 15 g. red P in 180 cc. HI (d. 1.70), then boiled 0.5 hr., cooled, dild. with  $H_2O$ , filtered, treated with hot soda and pptd. with HCl; 3 g. suspended in 20 cc. AcOH and heated on the  $H_2O$  bath with 5 cc.  $HNO_3$  (d. 1.30) yields 6.3 g. *2,4-dihydroxy-3-nitroquinoline* (g), long, flat, S-yellow prisms from AcOH, changes color about  $216-8^\circ$ , decomp. about  $225^\circ$ , sol. in  $NH_4OH$  and alkalies, takes up 1 mol.  $NH_3$ ; *silver salt*, lemon-yellow needles, deflagrates on heating. Heated 2 hrs. on the  $H_2O$  bath with  $POCl_3$  it gives *2,4-dichloro-4-nitroquinoline*, needles from alc., m.  $102^\circ$ , volatile with steam, violently attacks the mucous membranes, produces painful burns on the skin, reduced by 30% HCl and Sn sponge to *3-aminoquinoline*, m.  $84-5^\circ$ . (d) can be conveniently prepd. by slowly adding *o*- $O_2NC_6H_4COCl$  (from 12.5 g. of the acid and 16 g.  $PCl_5$ ) in 30 cc.  $Et_2O$  to the magma obtained from 3.5 g. Na in 50 cc. alc. and 8.5 cc.  $NCCH_3CO_2Et$  in 30 cc.  $Et_2O$ , shaking after 2 hrs. with  $H_2O$  and satg. the aq. layer with HCl; the resulting *ethyl [o-nitrobenzoyl]cyanoacetate* (12 g.), needles from alc., m.  $91^\circ$ , gives a yellow-red color with alc.  $FeCl_3$ ; 5 g. slowly added to 20 cc. hot HI and 2 g. red P, boiled 0.5 hr., cooled, filtered, dissolved in warm  $H_2O$ , decolorized with  $SO_2$ , filtered and treated with excess of  $NH_4OH$ , gives 1.8 g. (d). In dil. HCl with somewhat more than the calcd. amt. of nitrate it yields the *iminoquinisatoxime*,  $C_8H_4NHC(:NH).C(:NOH).CO$  or  $C_8H_4N:C(NH_2).C(:NOH).CO$ , liver-colored micro-

cryst. spheres, red-brown to gray-yellow when dry, sol. in KOH with blood-red color, depositing the cinnabar-red *potassium salt* from excess of KOH; the  $CO_2$  of the air repts. the free oxime from the alk. soln. Warm concd. HCl also dissolves the oxime with blood-red color and on cooling deposits the *hydrochloride* in orange-yellow needles;

hot  $\text{HNO}_3$  (d. 1.34) gives (g); Sn sponge and 20% HCl yield the *hydrochloride*, crystals with 1  $\text{H}_2\text{O}$ , of 2(or 3)-*amino-3,4*(or 2,4)-*dihydroxyquinoline*, silky needles with 1  $\text{H}_2\text{O}$ , does not m.  $300^\circ$ , sol. in alkalis; finally the oxime, rubbed with HI (b.  $127^\circ$ ) and decolorized with  $\text{PH}_4\text{I}$ , gives 2,3-*diamino-4-hydroxyquinoline*, pptd. by  $\text{NH}_4\text{OH}$  in long, flattened needles, sol. only in traces in  $\text{H}_2\text{O}$ , the soln. reducing  $\text{AgNO}_3$ , sol. in alkalis, is dibasic, fuming HCl pptg. from the soln. in dil. HCl a *dihydrochloride* in needles. Quiniasatoxime (Baeyer and Homolka, *Beilstein*, IV, 286) with Sn sponge and cold 20% HCl gives the *hydrochloride*, needles with 1  $\text{H}_2\text{O}$ , does not m.  $285^\circ$ , of 2,4-*dihydroxy-3-aminoquinoline*, pptd. by  $\text{KOAc}$  in micro-needles, does not m.  $280^\circ$ , darkens at  $100^\circ$  or on long standing in a desiccator, dissolves very slightly in  $\text{H}_2\text{O}$ , the soln. reducing  $\text{AgNO}_3$  on warming. It is easily sol. in  $\text{NH}_4\text{OH}$ , the soln. soon becoming blue and covered with a Cu-colored film. The same base is obtained as the *hydriodide*, needles with 1  $\text{H}_2\text{O}$ , when the oxime is stirred with HI and decolorized with  $\text{PH}_4\text{I}$ . The HCl and HI salts are partially hydrolyzed by  $\text{H}_2\text{O}$ . The base is also obtained from (g) by boiling with Sn and HCl. Its *acetyl derivative*, from the HCl salt heated on the  $\text{H}_2\text{O}$  bath with  $\text{KOAc}$  and  $\text{Ac}_2\text{O}$ , decomps. above  $200^\circ$ , does not m.  $285^\circ$ . CHAS. A. ROUILLER.

**Mono- and dichlorophenanthrenes.** HÅKAN SANDQVIST AND A. HAGELIN. Univ. Upsala. *Ber.* 51, 1515-26(1918).—When 100 g. phenanthrene in 130 cc.  $\text{CS}_2$  or  $\text{CCl}_4$  is treated at about  $0^\circ$  during the course of 2-3 hrs. with 35-60 g. Cl in  $\text{CS}_2$  or  $\text{CCl}_4$  and allowed to stand overnight, there seps. about 0.1 g. of a yellow, felted mass, apparently a trichloroanthracene, m.  $373^\circ$  (cor.) and then sublimes in light yellow needles. The filtrate on evapn. leaves an oily residue solidifying on cooling to a mixt. of 2 kinds of crystals, sepd. by means of alc. into difficultly sol., long, light yellow needles of 9,10-dichloroanthracene, m.  $208-9^\circ$  (usually about  $3^\circ$ ), and about 10 g. 9,10-phenanthrene *dichloride* (a). The residual oil on distn. evolves HCl between  $100-75^\circ$  and yields unchanged phenanthrene ( $330-40^\circ$ ), 10-chlorophenanthrene (b) ( $350-60^\circ$ ) and a little anthracene (above  $360^\circ$ ); total distillate, about 50 g. Much tar remains behind. (a) decomps. markedly, even at room temp., in a few days, also in alc. soln. The presence of (b) on the solid crystals of (a) catalyzes their decompn. considerably, so that it is difficult to det. the exact m. p. of (a), which is  $161^\circ$  (cor.) (evolution of HCl and formation of (b)). (b), obtained in 40-5 g. yield from 100 g. phenanthrene by heating the mixt. of (a) and (b) 1 hr. at  $150-75^\circ$ , m.  $53-3.5^\circ$ , b<sub>mm</sub>  $370^\circ$  (cor.),  $d_{44}^{25}$  1.2310,  $d_{46}^{25}$  1.2163, seps. from AcOH in long, fine needles, gives phenanthrenequinone in good yield on oxidation; *picrate*, fiery yellow, prismatic needles from alc., m.  $115^\circ$  (cor.). In attempting to convert the phenanthrene obtained in the distillate into (b) by treating it in  $\text{CS}_2$  with dry Cl there was obtained 9,10-dichlorophenanthrene, needles from alc., m.  $160-0.5^\circ$ , also prepd. in 75% yield by treating (b) in cold  $\text{CS}_2$  or  $\text{CCl}_4$  with Cl, partially oxidized in AcOH by a large excess of  $\text{CrO}_3$  to phenanthrenequinone, forms no *picrate* in alc., converted by  $\text{H}_2\text{SO}_4$  into a sulfonic acid showing the same remarkable phenomena of anisotropy and viscosity as other halogen-substituted sulfonic acids of phenanthrene. 1-10-Chlorophenanthrene-3(or 6)-sulfonic acid (c) (C. A. 12, 807) is obtained as the K salt in 80-90% yield by treating 30 g. (b), fused on the  $\text{H}_2\text{O}$  bath, with 25 g. of warm 96-7%  $\text{H}_2\text{SO}_4$ , heating 30-45 min. on the  $\text{H}_2\text{O}$  bath, then adding 10 g. of warm acid, continuing the heating until the mixt. becomes solid, dissolving in 1-2 l.  $\text{H}_2\text{O}$ , filtering from unchanged (b) and neutralizing hot with KOH. With  $\text{PCl}_5$  over a free flame the chloride of (c) gives 1-10,3(or 6)-*dichlorophenanthrene*, needles from alc., m.  $125-5.5^\circ$  (cor.), identical with the compd. obtained as by-product in the prepn. of 3-chlorophenanthrene (C. A. 4, 762), converted by  $\text{CrO}_3$  in boiling AcOH into 3-chlorophenanthrenequinone, orange-yellow needles from AcOH, m.  $261^\circ$  (cor.), insol. in  $\text{NaHSO}_4$ , and yielding with  $\text{NH}_4\text{OH.HCl}$  in boiling alc. a 9(or 10)-*oxime*, yellow needles from alc., m.  $204^\circ$  (cor.) (decompn.). Potassium 11-10-chlorophenanthrene-3(or 6)-sulfonate,

needles, is prepd. by treating 10 g. K phenanthrene-3-sulfonate (*d*) in 600 cc. H<sub>2</sub>O at 50° with 1000-1200 cc. satd. Cl water in the course of several hrs. and concg. (yield, 22 g. crude salt from 85 g. (*d*)). The free acid is prepd. from 0.5 g. of the chloride (see below) by heating with 2 cc. of H<sub>2</sub>O at 140-50° for 15 min.; on cooling the soln. becomes extremely viscous and turbid and under the polarizing microscope appears cryst., of the same type as the Br analog; the soln. becomes clear at 35°. The HCl escapes quite easily on the H<sub>2</sub>O bath. The acid, after standing in the air, m. 150° (vigorous gas evolution), loses 8.4% H<sub>2</sub>O over H<sub>2</sub>SO<sub>4</sub> and 4.7% more at 115° (13.1% corresponds to about 2.5 mols. H<sub>2</sub>O), and then m. 207°. A dil. soln. of the acid free from HCl is not strikingly viscous but becomes so when treated with a strong acid (HNO<sub>3</sub> or HCl), and even when free from HCl it forms a cryst. liquid in sufficiently concd. soln. The chloride, from the K salt and PCl<sub>5</sub>, seps. from C<sub>6</sub>H<sub>6</sub> as a gray powder of irregular leaflets, m. 171°, which, heated over a free flame with PCl<sub>5</sub>, gives *II-10,3* (or *6*)-dichlorophenanthrene, needles from alc., m. 113°, oxidized by CrO<sub>3</sub>-AcOH to 3-chlorophenanthrenequinone. In the prepn of the di-Cl compd. is also formed a more difficultly sol. substance, probably 3,9,10-trichlorophenanthrene, m. 109-9.5°.

CHAS. A. ROUITLER.

**Alteration of iodoform in direct sunlight alone and in solution.** E. COMANDUCCI AND G. MEDURI. *Gazz. chim. ital.* 48, I, 238-47(1918).—Many authors state that CHI<sub>3</sub>, both as a solid or in soln. in org. solvents, is changed in the light. Thus the CS<sub>2</sub> soln. is said to be very sensitive to light and is quickly changed to violet: EtOH, CHCl<sub>3</sub>, benzine and petr. ether solns. behave similarly. The various statements in the literature are fully reviewed. C. and M. have now investigated the decompn. of CHI<sub>3</sub> in 19 org. solvents. The results show that the relative velocity of decompn. for the solvents used decreases in the order: petr. ether, CS<sub>2</sub>, AcOEt, PhCH:CHCHO, Me<sub>2</sub>CO, guaiacol, CHBr<sub>3</sub>, Et<sub>2</sub>O, turpentine, oleic acid, MeOH, EtOH, C<sub>6</sub>H<sub>6</sub>, PhNO<sub>2</sub>, AmOH, CHCl<sub>3</sub>, allyl alc., glycerol and olive oil. With respect to the % of the CHI<sub>3</sub> changed for the same time and concn. the results were as follows: CHCl<sub>3</sub> 49.60, glycerol 39.16, Me<sub>2</sub>CO 31.8, allyl alc. 22.85, CS<sub>2</sub> 13, AmOH 8.05, guaiacol 6.56, CHBr<sub>3</sub> 6.55, EtOH 6.33, PhNO<sub>2</sub> 5, Et<sub>2</sub>O 3.84, AcOEt 3.55, C<sub>6</sub>H<sub>6</sub> 3, oleic acid 1.90, PhCH:CHCHO 1.82, MeOH 0.65, petr. ether 0.294, turpentine trace, olive oil trace. By a comparison of these 2 sets of results, it is clear that in the group of alcs., while the velocity of decompn. of CHI<sub>3</sub> diminishes with the increase of the number of C atoms, the quantity of CHI<sub>3</sub> decompd. increases and besides in the case of MeOH the I and HI produced cause a partial oxidation with the formation of aldehyde. In the group of unsatd. compds. there is an analogous behavior but the velocity of decompn. of CHI<sub>3</sub> decreases with the increase of the mol. wt. while the amt. of CHI<sub>3</sub> decompd. diminishes. Iodo compds. are formed by the addition of I to the unsatd. bond. With regard to the other solvents it was found that while the hydrocarbons of petr. ether which are very stable in the light permit the rapid decompn. of CHI<sub>3</sub> this decompn. stops very soon, while for C<sub>6</sub>H<sub>6</sub>, a very stable aromatic hydrocarbon, the decompn. is slow and the amt. of CHI<sub>3</sub> decompd. is also small. The behavior of turpentine resembles that of petr. ether. For CHCl<sub>3</sub>, CHBr<sub>3</sub> and CS<sub>2</sub>, of which the latter 2 are very easily transformed in the light, it was also found that they markedly increase the decompn. of CHI<sub>3</sub>. In CHCl<sub>3</sub> the velocity of decompn. is slow but the amt. transformed is large and this is related to its small stability in light, as was shown by blank expts. In CS<sub>2</sub> the transformation is complete in air but in a sealed container stops presently. Me<sub>2</sub>CO which is easily condensed in the presence of halogens and halogen acids aids the decompn. of CHI<sub>3</sub> much by producing I and HI and condensation products of Me<sub>2</sub>CO itself. Of all the solvents used olive oil was the best for in it the decompn. of CHI<sub>3</sub> is nearly zero and this fact has practical importance. Glycerol, how-

ever, is to be rejected as a solvent for while it strongly retards the velocity of decompn. of  $\text{CHI}_3$ , it does not prevent the decompn. of a large amt. even out of contact with the air and produces much I and HI. The advantage of glycerol is that the  $\text{CHI}_3$  soln. may be dild. with  $\text{H}_2\text{O}$  without pptg. it. Such glycerol and hydroglycerol solns. should be used at once, especially if used hypodermically, because on standing for a time they become too acid and irritating. The  $\text{CHBr}_3$  solns. of  $\text{CHI}_3$  ought to be valuable since they give rise to iodobromo org. compds. and the action of Br may be added to that of I. The clinical use of some of these solns. will be reported upon in another paper.

E. J. WITZEMANN.

**Oxidation of santonin by organic peracids.** G. CUSMANO. Florence. *Gazz. chim. ital.* 48, I, 248-53(1919).—Four monohydroxysantonins,  $\alpha$ ,  $\beta$ ,  $\gamma$  and  $\delta$ , have been described and none have been obtained by *in vitro* oxidation of santonin, (a). The first 2 are the so-called santogenins found in the urine of dogs and rabbits, resp., by Jaffe after feeding (a). The 3rd is artemisin, that accompanies (a) in the flowers of *Artemisia maritima*. The 4th is isoartemisin, obtained by Wedekind and Koch (*Ber.* 38, 1845(1905)) by the action of alkali on monochlorosantonin. W. and K. could not regulate the attack of the oxidizing agent. Angeli and Marino (*C. A.* 2, 2953) found that a dihydroxysantonin,  $\text{C}_{15}\text{H}_{11}\text{O}_6$ , could be obtained by the action of dil.  $\text{KMnO}_4$ . C. (*Rend. soc. chim. ital.* 1914, 1) found that oxidation could be further controlled by using perbenzoic and peracetic acids and obtained 2 mono-HO derivs., one of which is identical with the isoartemisin of W. and K.; the other was new and was assigned the letter  $\epsilon$ . (a) + 2 mols. perbenzoic acid in  $\text{CHCl}_3$  were kept in an open beaker at  $10^\circ$  for some days until all the  $\text{CHCl}_3$  was evapd. In the solid residue freed from  $\text{BzOH}$  most of the (a) was found unchanged. After exposing to the light nearly all of the material rapidly became yellow. Some colorless crystals remained which deposited from 95% EtOH isoartemisin or  $\delta$ -hydroxysantonin, (b), white prisms, m.  $212^\circ$ . The alk. soln. used to remove the  $\text{BzOH}$  was acidified and filtered and after 2 days sepd.  $\epsilon$ -hydroxysantonin, (c), rosets, m.  $154^\circ$ . A better result was obtained thus: 10 g. (a) + 10 cc. perhydrol + 35 cc. glacial AcOH were heated in a  $\text{H}_2\text{O}$  bath at  $80^\circ$ . After 20 hrs. 10 cc. perhydrol were again added and heating was continued 20 hrs. more. The soln. was then concd. to a syrup on the  $\text{H}_2\text{O}$  bath and treated with a soln. of  $\text{Na}_2\text{CO}_3$  which dissolved a part and left a resinous mass. This was washed with  $\text{H}_2\text{O}$  and dissolved in boiling EtOH; impure (b) sepd. which after exposure to light was extd. again with EtOH. The various fractions of crystals were treated in this way and the (c) was always recovered from the EtOH extn. mother liquors. 15 g. (a) gave 2 g. (b) and 1.2 g. (c) in this way; much unchanged (a) was recovered. (c) remains unchanged when heated for some time at  $154^\circ$ , it does not change color in the light and fails to react with  $\text{PhCNO}$  even in the sealed tube at  $130^\circ$ . In the cold it reacts with  $\text{PhNHNH}_2$  to give the *monophenylhydrazone* of (c), m.  $280^\circ$ . Although (a) dissolves easily in aq. alkalis, (c) does not dissolve, but in hot EtONa solns. it gives the blood-red salt of hydroxysantoninic acid. This soln. dild. with  $\text{H}_2\text{O}$  is decolorized after long heating. On cong. the soln. the salt seps. as a glassy mass. The free acid is obtained as a colorless oil, little sol. in cold  $\text{H}_2\text{O}$ , that crysts. slowly, m.  $100^\circ$  (about); in dil.  $\text{H}_2\text{SO}_4$  it gives (c) again. 0.3 g. (c) in 3 cc.  $\text{HCl}$  (d. 1.19) dissolves rapidly and a new *monochlorosantonin*, (d),  $\text{C}_{15}\text{H}_{11}\text{ClO}_5$ , m.  $196^\circ$ , is obtained. (d) is thus isomeric with that of Sestini (*Bull. soc. chim.* 5, 202(1866)) which m.  $235^\circ$  and is more stable with dil. boiling EtOH. (d) is transformed into (c) by boiling a few mins. with dil. EtOH. The same reaction takes place in alc. KOH. (d) treated in EtOH with powdered Zn and a few drops of AcOH gave (a).

E. J. WITZEMANN.

**The aromatic nitro derivatives.** VII. The formation of the nitrohydrazo compounds. M. GIUA. Sassari. *Gazz. chim. ital.* 48, II, 8-17(1918); cf. *C. A.* 8, 2731;

9, 1479, 2089; 10, 598, 1175, 1858; 11, 1163.—The prepn. of the  $\text{NO}_2$  derivs. of hydrazobenzene and its homologs is not possible by direct nitration. The one method known is that of Fischer (*Ann.* 190, 131(1878); 253, 2(1889)) which consists in treating *o*- or *p*-chloronitro derivs. of  $\text{C}_6\text{H}_4$  with  $\text{PhNHNH}_2$  or its derivs. (Willgerodt, etc., *J. prakt. Chem.* [2] 37, 345, 454(1888); 40, 264(1889); 43, 177(1891); 44, 67(1891)). Much work has been done on the behavior of  $\text{NO}_2$  compds. with  $\text{PhNHNH}_2$  but mostly with poly- $\text{NO}_2$  derivs. with the  $\text{NO}_2$  groups meta with respect to each other. Sommer (*J. prakt. Chem.* 67, 513(1903)) studying the action of  $\text{PhNHNH}_2$  on trinitrotolyl-methylnitroamine and trinitromethyl-*p*-toluidine obtained hydrazobenzene. Thus with labile  $\text{NO}_2$  groups  $\text{PhNHNH}_2$  has not a reducing but a substituting action. This reaction G. has found is general and constitutes a good method of prepn. of nitrohydrazo compds. G. has studied the action of  $\text{PhNHNH}_2$  on  $\beta$ - and  $\gamma$ - $\text{MeC}_6\text{H}_4(\text{NO}_2)_2$  and on 3,4,5-( $\text{O}_2\text{N}$ ) $_3\text{C}_6\text{H}_2\text{CO}_2\text{H}$  and its Me ester, compds. containing a mobile  $\text{NO}_2$  as G. has previously shown. It was found that the hydrazo compds. are easily formed in EtOH at room temp. and sep. as orange-yellow cryst. compds. The  $\text{HNO}_2$  formed by the reaction reacts with the excess of  $\text{PhNHNH}_2$  thus:  $\text{PhNHNH}_2 + 2\text{HONO} \rightarrow 4\text{H}_2\text{O} + 4\text{N}_2 + 3\text{C}_6\text{H}_6$ . The nitrohydrazo compds. thus obtained that have a  $\text{NO}_2$  group in the *o*-position to the hydrazino group easily lose a mol.  $\text{H}_2\text{O}$  to give nitrosoazo compds. or "azimidoxides." The action of  $\text{PhNHNH}_2$  on 3,4,6-( $\text{O}_2\text{N}$ ) $_3\text{C}_6\text{H}_2\text{CO}_2\text{H}$  is characteristic. In the presence of the  $\text{CO}_2\text{H}$  group the formation of the phenylhydrazide was to be expected. With *sym*-( $\text{O}_2\text{N}$ ) $_3\text{C}_6\text{H}_2\text{CO}_2\text{H}$  a white substance, m.  $145^\circ$  (decompn.) is formed but with the 1st acid the reaction is rapid and a yellow solid seps. at once. 2 g.  $\gamma$ - $\text{MeC}_6\text{H}_4(\text{NO}_2)_2$  in 10 cc. MeOH treated with 1.04 g.  $\text{PhNHNH}_2$  gave a dark red color at once and sepd. 2,4-dinitro-5-methylhydrazobenzene, (a), red-yellow plates, m.  $155^\circ$  (decompn.). (a) in alc. treated with dry HCl becomes carmine-red and seps. 2-nitroso-4-nitro-5-methylazobenzene, golden-yellow laminas, m.  $120-1^\circ$ .  $\beta$ - $\text{MeC}_6\text{H}_4(\text{NO}_2)_2$  reacting with  $\text{PhNHNH}_2$  in EtOH seps. in 10 mins. 2,6-dinitro-5-methylhydrazobenzene, red prisms, m.  $137^\circ$  (decompn.) which in abs. EtOH with HCl gas gives nitroso-nitro-methylazobenzene, shining needles, m.  $154^\circ$ . 5 g. 3,4,6-( $\text{O}_2\text{N}$ ) $_3\text{C}_6\text{H}_2\text{CO}_2\text{H}$  in 20 cc. EtOH + 6 g.  $\text{PhNHNH}_2$  gave a ppt. of 2,4-dinitro-5-carboxyhydrazobenzene, (b), red-yellow crystals, m.  $135^\circ$  (decompn.). A brownish  $\text{H}_2\text{O}$ -insol. compd. that m. below  $100^\circ$  was obtained, but not studied further. Aq. (b) with  $\text{AgNO}_3$  gave the silver salt of (b) which rapidly decomps. (b) reduces  $\text{NH}_3\text{-Ag}_2\text{O}$  solns. rapidly. (b) in MeOH with dry HCl gas gave 2-nitroso-4-nitro-5-carboxyazobenzene, golden yellow needles, m.  $244^\circ$  (decompn.). 1.75 g. 3,4,6-( $\text{O}_2\text{N}$ ) $_3\text{C}_6\text{H}_2\text{CO}_2\text{Me}$  in 5 cc. EtOH + 1.5 g.  $\text{PhNHNH}_2$  gave at once 2,4-dinitro-5-carbomethoxyhydrazobenzene, orange-yellow, m.  $177-8^\circ$ . From MeOH containing  $\text{C}_6\text{H}_6$  are obtained prismatic yellow needles, m.  $147^\circ$ , begin to evolve gas  $175-8^\circ$ , which are apparently an isomer (Willgerodt, Böhm, *J. prakt. Chem.* 43, 482(1891)). E. J. W.

**Pyrrole blacks.** A. ANGELI. *Gazz. chim. ital.* 48, II, 21-5(1918).—In previous papers (*C. A.* 11, 793) A. has described the coloring matters obtained by the action of  $\text{H}_2\text{O}_2$  in AcOH solns. on pyrrole. But pyrrole should give coloring matters under other conditions also. Expts. have shown that the majority of the oxidizing agents give intensely colored black or brown products with pyrrole, some of which are sol. and some insol. in alkalis. They were all obtained in acid solns. A soln. of  $\text{C}_4\text{H}_5\text{N}$  in AcOH treated with  $\text{K}_2\text{Cr}_2\text{O}_7$  soln. ppts. a black powder at once, and if a piece of cotton moistened with the soln. is treated with  $\text{K}_2\text{Cr}_2\text{O}_7$  a black dye fast to light and soap is produced upon the fibers. The black ppt. contains Cr even after contact with dil.  $\text{H}_2\text{SO}_4$  for some days although much of it is removed in this way. The black product easily dissolves when further treated with  $\text{K}_2\text{Cr}_2\text{O}_7$  + dil.  $\text{H}_2\text{SO}_4$ . By extg. with  $\text{Et}_2\text{O}$  maleinimide identical with that prepd. by Plancher is obtained. This

shows that the coloring matter contains the pyrrole residue and just as  $\text{PhNH}_2 \rightarrow$  aniline black  $\rightarrow$  quinone so pyrrole  $\rightarrow$  pyrrole black  $\rightarrow$  maleinimide, in which the latter is the quinone of pyrrole. The pyrrole black from  $\text{H}_2\text{O}_2$  gives succinimide on further oxidation. Similar coloring matters are obtained by oxidizing pyrrole in dil.  $\text{H}_2\text{SO}_4$  soln. in which pyrrole is polymerized. A. has shown that tripyrrole as well as the amorphous base formed at the same time both give black ppts. when treated with  $\text{K}_2\text{Cr}_2\text{O}_7$  in dil.  $\text{H}_2\text{SO}_4$ . But if the  $\text{H}_2\text{SO}_4$  solns. are first treated with excess  $\text{AcONa}$  only a little black ppt. is formed after some days. The limpid  $\text{H}_2\text{SO}_4$  soln. of  $\text{C}_4\text{H}_5\text{N}$  becomes green at once on adding  $\text{H}_2\text{O}_2$  and in 1 hr. a black powder is pptd. which is not sol. in alkali. A similar reaction is obtained with  $\text{FeCl}_3$ . These facts demonstrate that the formation of pyrrole black is probably preceded by a more or less rapid polymerization of pyrrole. The unproved formula (I) has been assigned to tripyrrole (Dennstedt, Voigtländer, *Ber.* 27, 478(1894)) which A. considers does not explain its behavior. He considers that at least part of the mols. may be united as in (II). Such products as (II) could explain the formation of the products obtained. A. attempted to treat a soln. of pyrrole with  $\text{PbO}_2$  (by which indacene (indace) is

oxidized to dehydroindacene) and obtained a brown substance, but as yet no definite products. Samuely has explained the formation of melanin by assuming that the albuminoid mol. gives up a cyclic compd., which on the basis of A.'s expts. may be pyrrole. Pyrrole derivs. are widely diffused in organisms. It is known that tyrosine with  $\text{O}_2$  and tyrosinase at first becomes red, then brown and finally seps. a black product, a melanin, while the liquid is perfectly colorless. This A. interprets as an oxidation in which the side chain is converted into pyrrole by the destruction of the aromatic ring, which latter process is favored by the  $p\text{-OH}$  group of tyrosine. A. has not had opportunity to study the action of oxidases on pyrrole and its derivs.

E. J. WITZEMANN.

**Electrolytic reduction of hydroxyazo compounds.** E. PUXEDDU. Univ. Cagliari. *Gazz. chim. ital.* 48, II, 25-30(1918).—P. has previously studied (*Gazz. chim. ital.* 35, II, 598(1905); 36, II, 1(1906)) the reduction of hydroxyazo compds. with  $\text{PhNHNH}_2$  and found that  $\text{HOR.N:NPh} + 2\text{PhNHNH}_2 \rightarrow \text{HOR.NH}_2 + \text{PhNH}_2 + 2\text{C}_6\text{H}_6 + 2\text{N}_2$  expresses the results. The expts. were extended to the azo derivs. of the aromatic HO acids and HO aldehydes and to the diazo compds. of the phenols (*C. A.* 10, 2882) with similar results so that this was a convenient way of obtaining aminophenols, diaminophenols, aminohydroxy acids and aminohydroxy aldehydes (*C. A.* 10, 2881). P. has now studied the electrolytic reduction of some of the azo derivs. The results on the reduction of  $p\text{-HOC}_6\text{H}_4\text{N}_2\text{Ph}$  are given here. The work of Noyes and Clement (*Ber.* 26, 990(1893)) and Gattermann (*Ber.* 26, 1844(1893)) on the electrolytic reduction of  $\text{PhNO}_2$  is fully reviewed. P. found that in the electrolytic reduction of hydroxyazo compds. the reaction takes place thus:  $\text{HOR.N:NR}' + 2\text{H}_2 \rightarrow \text{HORNH}_2 + \text{R}'\text{NH}_2$  in which the double N bond is broken and its affinities are satd. with  $\text{H}_2$  developed in the cathode liquid. Hydroxyazo compds. have not previously been reduced in this way. The expected result was obtained. The app. used was simple. A porous cup containing 5 g.  $p\text{-HOC}_6\text{H}_4\text{N}_2\text{Ph}$  in pure EtOH containing 25 g. HCl and a Pt plate were placed in a cylindrical glass beaker containing an HCl-EtOH soln. and a Pt anode. The reduction was carried on slowly with 1.5-2.0 amp. at 6

volts for 96 hrs. (current d. 0.088 amp. per sq. cm.) and gave a brown liquid which on evapn. and cooling sepd. reddish white prismatic crystals. After treating with  $\text{NaHCO}_3$  the  $p\text{-HOC}_6\text{H}_4\text{NH}_2$  sepd. as red leaves, m.  $184-5^\circ$  (decompn.), which gives Loessen's reaction with  $\text{HCl}$  and  $\text{Ca}(\text{OCl})_2$  soln. (a violet, then green color). The mother liquor from the  $p\text{-HOC}_6\text{H}_4\text{NH}_2$  alkalinized with  $\text{Na}_2\text{CO}_3$  and extd. with  $\text{Et}_2\text{O}$  gave finally some  $\text{PhNH}_2$  also. P. also attempted to reduce  $p\text{-HOC}_6\text{H}_4\text{N}_2\text{Ph}$  in a mixt. of 150 cc. concd.  $\text{H}_2\text{SO}_4$  + 30 cc. glacial  $\text{AcOH}$  in the same app. under the same conditions. No  $p\text{-HOC}_6\text{H}_4\text{NH}_2$  was obtained. E. J. WITZEMANN.

Some analogies in the behavior of the rings of diazoimide and diazomethane. E. OLIVERI-MANDALA. *Gazz. chim. ital.* 48, II, 35-9(1918).—Guided by the analogies of the ring of  $\text{N}_2\text{H}$  to that of  $\text{N}_2\text{CH}_2$  O.-M. has carried out a series of researches part of which have already been published (*C. A.* 5, 1091, 2636, 3571; 6, 625; 7, 2934, 3495, 3755; 8, 1272; 9, 70, 71; 10, 596, 1514) and which are briefly summarized here. It was found that whatever the mechanism of reaction, both compds. show a great tendency to assume other atoms and form more stable rings containing more atoms. While  $\text{CH}_2\text{N}_2$  combines directly with 2 atoms by opening the ring,  $\text{N}_2\text{H}$  does not do this but the H and triazo group are added first and then under suitable conditions the ring is reformed. This latter step is only possible with compds. containing acetylene or unsatd. hydrocarbon bonds thus: (1)  $>\text{C}:\text{N}:\text{R} + \text{N}_2\text{H} \longrightarrow \text{N}_2\text{CH}:\text{N}:\text{R}$  or (2)  $-\text{C}\equiv\text{C} + \text{N}_2\text{H} \longrightarrow -\text{HC}:\text{CN}_2$  and the 2 products thus formed may be isomerized into  $\text{N}:\text{N}:\text{NR}:\text{CH}:\text{N}$  and  $\text{NH}:\text{N}:\text{N}:\text{C}(\cdot):\text{C}(\cdot)$ , resp. With compds. with the ethylene

bond addition compds. are obtained showing that unlike  $\text{CH}_2\text{N}_2$ , the  $\text{HN}_2$  adds without opening the N ring and these react again if the new mol. contains an unsatd. valence. With  $\text{RN}:\text{CO}$  derivs.  $\text{N}_2\text{H}$  gives only  $\text{RNHCON}_2$  and not a deriv. of oxytetrazole.  $(\text{CN})_2$  reacts with  $2\text{HN}_2$  to give  $\text{HN}:\text{N}:\text{N}:\text{N}:\text{C}:\text{C}:\text{N}:\text{N}:\text{NH}$ , thus closing both

rings. The behavior of some azides of derivs. of thiocarbamic acids in the presence of alkalis bring out the similarities with  $\text{CH}_2\text{N}_2$  still more strongly. Thus  $\text{N}_2\text{HC}:\text{CO}:\text{NHR}$  gives  $\text{N}:\text{N}:\text{CH}:\text{COH}:\text{NR}$  while  $\text{N}_2\text{CSNHR}$  gives  $\text{N}:\text{N}:\text{N}:\text{C}(\text{SH})\text{NR}$ . The reactions

are classed in 2 groups of 5 types: (I) formation of azides (a) with compds. with adjacent double bonds like esters of isothiocyanic acid, isocyanides, ketenes and  $\text{CS}_2$ , thus:  $\text{R}:\text{N}:\text{C}:\text{S} + \text{N}_2\text{H} \longrightarrow \text{RNH}:\text{CSN}_2$ ; (b) with compds. having ethylene bonds, by which quinone gives  $\text{HOC}:\text{CH}:\text{CH}:\text{C}(\text{OH})\text{CH}:\text{CN}_2$ ; (II) formation of tetrazole and

oesotriazole rings (c) with compds. containing a bivalent C atom, by which  $:\text{C}:\text{N}:\text{R} \longrightarrow \text{RN}:\text{N}:\text{N}:\text{N}:\text{CH}$ ; (d) with compds. having triple bonds between C and N such as

$(\text{CN})_2$ ,  $\text{CNBr}$ , and  $\text{NCCO}_2\text{Et}$ ; (e) with compds. having the acetylene bond such as  $(\text{HO}_2\text{CC}\cdot)_2$ , propiolic acid and propargylic acid. E. J. WITZEMANN.

Hydrosulfonic derivatives of citral. GIOVANNI ROMEO. Univ. Messina. *Gazz. chim. ital.* 48, I, 45-52(1918).—Citral contained in the essential oils of lemon, of *Backhousia citrodora*, of lemongrass (*Andropogon citratus*), etc., forms various complexes with alk. sulfites. The normal combination of  $\text{NaHSO}_3$  was used to purify the aldehyde (Semmler, *Ber.* 23, 2966(1890); Dodge, *Am. Chem. J.* 12, 553(1890)). D. also found  $\text{C}_{12}\text{H}_{16}\text{O}_2\cdot 2\text{NaHSO}_3\cdot 4\text{Na}_2\text{SO}_3\cdot 50\text{H}_2\text{O}$ . Tiemann (*Ber.* 31, 3297) studied these derivs. and obtained a new monohydrosulfonic deriv. as well as 2 dihydrosulfonic derivs. The normal  $\text{NaHSO}_3$  compd. of citral, (a),  $\text{Me}_2\text{C}:\text{CH}:(\text{CH}_2)_2\text{CMe}:\text{CH}:\text{CH}(\text{OH})\text{SO}_3\text{Na}$ , is formed quant. when the aldehyde is treated with  $\text{NaHSO}_3$  containing enough free acid ( $\text{AcOH}$  for instance). The cryst. compd. gives citral again when treated with

NaOH. The stable dihydrodisulfonic deriv. of citral (*b*),  $C_9H_{17}(SO_3Na)_2.COH$ , is formed quant. when (*a*) is allowed to stand for some hrs. in contact with an excess of  $NaHSO_3$  soln. which is kept acid. (*b*) is a very deliquescent solid which is not decompd. even by hot alkalis and contains the COH group unchanged. Four formulas are possible depending on how the  $NaHSO_3$  mols. add to the 2 unsatd. bonds. The labile dihydrodisulfonic deriv. of citral (*c*),  $C_9H_{17}(SO_3Na)_2.CHO$ , is formed when aq.  $Na_2SO_3$  is agitated with citral and the NaOH formed neutralized with an acid. (*c*) is decompd. by alkalis into  $NaHSO_3$  and citral. The COH group in (*c*) is free and the compd. may be represented by 4 formulas. (*c*) is a cryst. compd. neutral in reaction and is converted into (*b*) by inorg. acids and more slowly by org. acids. (*c*) when agitated with aq. citral easily loses a mol. of  $NaHSO_3$ , giving sodium citralhydrosulfonate,  $C_9H_{16}(SO_3Na).COH$ , which is likewise a solid, the aq. solns. of which give citral on adding KOH. It contains the COH group unchanged. Besides the above there should be 4 isomeric trihydrotrisulfonic derivs. of citral, or (*b*) and (*c*) with the COH bound to  $NaHSO_3$ . In 1905 R. (*Atti VI Congresso intern. chim. appl., Roma, I, 295*) reported that 3 mols.  $NaHSO_3$  are combined with citral in aq. soln. and now he has isolated the cryst. compd. It was obtained as follows: 15 g. citral were added to a soln. of 80 g. dry  $Na_2SO_3$  + 32 g.  $NaHSO_3$  in 350 cc.  $H_2O$  and the mixt. agitated at ordinary temp. After about  $\frac{3}{4}$  hr. the mixt. was heated on the  $H_2O$  bath. The soln. was cooled and extd. twice with a little  $Et_2O$  and then concd. to 150 cc. on the  $H_2O$  bath; much  $Na_2SO_3$  crystd. out. The filtrate was concd. to 80 cc. and sepd. mixed sulfitcs and some org. salts. The yellowish filtrate was pptd. with about 6 vols. of 95%  $EtOH$  and allowed to stand 36 hrs. The ppt. was washed 4 times with  $EtOH$  and placed in a desiccator for a few days. The white product (31 g.) was pulverized and boiled under a condenser with 400 cc.  $MeOH$ . After filtering hot and standing a few days a trihydrotrisulfonic deriv. (*d*) sepd. as crystals. The soln. on evapg. gave a hygroscopic paste which was a mixt. of (*b*) or (*c*) with (*d*). It was further purified by extg. 3 times on a  $H_2O$  bath with 300 cc.  $EtOH$  in all. 3.5 g. of a white solid substance (*d*) was obtained, which is not deliquescent, reacts neutral in 10% soln. in  $H_2O$  and seps. citral when treated with KOH soln.  $HCl$  does not decomp. (*d*). The crystals of (*d*) that sepd. from the  $MeOH$  soln. on standing differ from the above in that they are not decompd. by KOH. Thus both the labile and stable forms of (*d*) were isolated in the cryst. form.

FRANK P. UNDERHILL.

The work of C. A. Pikelharing up to his seventieth birthday. H. ZWAARDEMAKER. *Arch. néerl. physiol.* 2, 451-64(1918); *Physiol. Abstracts* 3, 365.—The introductory paper to a jubilee number of *Arch. néerl. physiol.* in honor of Prof. Pikelharing. A brief account with bibliography is given of Pikelharing's valuable contributions to science. E. J. C.

The hydrolysis of proteins in the presence of extraneous materials and the origin and nature of the "humin" of a protein hydrolysate. ROSS AIKEN GORTNER. *Science* 48, 122-4(1919).—The conclusions of McHargue (*C. A.* 12, 375) are questioned. With reference to the applicability of the Van Slyke method for protein analysis to mixts. of casein and starch it is stated that "(1) proteins cannot be hydrolyzed with 20% HCl at atm. pressure in the presence of a considerable quantity of carbohydrates without appreciably altering certain of the N fractions of a Van Slyke analysis and (2) a Van Slyke analysis applied to feeding stuffs, contg. as they do non-protein nitrogenous compds., gives no valid index as to the presence or absence of any individual amino acid." McH. does not recognize that the insol. residue obtained in a casein-starch digestion is humin. E. J. C.

The hydrolysis of kafirin. D. BREESE JONES AND CARL O. JOHNS. U. S. Dept. Agr., Bur. Chem. *J. Biol. Chem.* 36, 323-34(1918).—Kafirin, the alc.-sol. protein of kafir, *Andropogon sorghum*, yields the following % of amino acids: glycine, 0.0; alanine, 8.08; valine, 4.26; leucine, 15.44; proline, 7.80; phenylalanine, 2.34; aspartic acid, 2.27; glutamic acid, 21.23; tyrosine, 5.49; cystine, 0.84; arginine, 1.59; histidine, 1.12; lysine, 0.95; tryptophan, present;  $\text{NH}_4$ , 3.46; total, 74.87. The details of the methods used in the hydrolysis and detns. are given in full. A. P. LOTHEP.

The effect of diffusion upon the conductivity of living tissue. W. J. V. OSTERHOUT. Harvard Univ. *J. Biol. Chem.* 36, 489-90(1918).—O. has shown "that electrolytes may be divided into two classes with respect to their effect on the elec. cond. of living tissues: those which produce a rise in resistance followed by a fall and those which produce only a decrease in resistance. Salts with bivalent and trivalent cations belong in the first class while those with monovalent cations belong in the second. Recently some apparent exceptions to this rule have been met with. The behavior of certain substances is anomalous in 3 respects: although they are monovalent salts they produce a rise in resistance, the rise is unusually brief in duration, and it occurs in dead as well as in living tissue." If tissue of *Laminaria* is transferred from artificial sea water to a similar soln. in which RbCl has been substituted for NaCl, there is a sharp rise in resistance which soon disappears. A drop in resistance occurs if the tissue is again transferred to ordinary artificial sea water. If the NaCl is substituted by LiCl, the resistance drops and there is a rise on replacing in the ordinary soln. Similar effects were observed with dead tissue but of smaller magnitude. "It is evident that these effects are due to diffusion. On transferring from artificial sea water made with NaCl to one in which RbCl takes the place of NaCl, the mols. of NaCl diffuse out of the tissues more rapidly than the larger mols. of RbCl can diffuse inward. Hence there is a temporary deficiency of salt in the tissue and the resistance accordingly rises. On the other hand, the smaller mols. of LiCl diffuse in faster than NaCl can diffuse out, causing a temporary excess of salt, which lowers the resistance. Any confusion which might be caused by disturbances of this sort may be easily avoided by control expts. made on dead tissue." A. P. LOTHEP.

The proteins of the peanut, *Arachis hypogaea*. III. The hydrolysis of arachin. CARL O. JOHNS AND D. BRERKE JONES. U. S. Dept. Agr., Bur. Chem. *J. Biol. Chem.* 36, 491-500(1918).—Arachin, the principal protein in the peanut, *Arachis hypogaea*, yields on hydrolysis the following % of the various amino acids: glycine, 0.00; alanine, 4.11; valine, 1.13; leucine, 3.88; proline, 1.37; phenylalanine, 2.6; aspartic acid, 5.25; glutamic acid, 16.69; tyrosine, 5.5; cystine, 0.85; arginine, 13.51; histidine, 1.88; lysine, 4.98; tryptophan, present;  $\text{NH}_4$ , 2.03; total, 63.78. The % of the basic amino acids was detd. by Van Slyke's method as well as by the direct method of Kossel and Kutscher and the values obtained by both methods agreed closely. More lysine was obtained by the former method than could be isolated by the direct method.

A. P. LOTHROP.

Action of enzymes on human placenta. VICTOR J. HARDING AND ELRID G. YOUNG. McGill Univ. *J. Biol. Chem.* 36, 575-80(1918).—Normal human placenta is readily digested by pepsin, trypsin and erepsin. When fed to a dog in the place of the beef in a diet of lean beef and carbohydrate, its digestibility is about the same as that of lean meat. The animals readily ate the ration containing the placenta powder and no ill effects on them were noticed. The placenta had almost the same N content (12.46%) as the meat and contained 8.82% of amino acid N (70.8% of the total N). Medical literature contains many references to placental feeding but there is no record of any study of the action of digestive juices upon the protein of the placenta or of its digestibility.

A. P. LOTHROP.

The globulins of the jack bean, *Canavalia ensiformis*. JAMES B. SUMNER. Cornell Univ. Med. College, Ithaca, N. Y. *J. Biol. Chem.* 37, 137-41(1919).—Jones and Johns (*C. A.* 11, 466) have isolated 2 globulins, concanavalin and canavalin from the jack bean but S. has found that it contains three globulins, two of which readily crystallize upon dialysis while the third appears to be incapable of crystg. The uncrystallizable globulin consists of spheroids which are readily sol. in 1% NaCl soln. This forms the greater part of the ppt. obtained by dialysis and should be called canavalin, the name applied by Jones and Johns to the ppt. obtained by complete satn. with  $(\text{NH}_4)_2\text{SO}_4$ . A minute amt. of material crysts. as needles which are slowly sol. in 10% NaCl soln. and are not sol. in alk. unless an excess is present. This material S. has named concanavalin B. The third globulin crysts. in bisphenoid form, is present in moderate amts. and is insol. in any but concd. NaCl solns. The crystals when not recently formed probably have an outer layer of protein and will dissolve only in hot NaCl soln. This globulin is called concanavalin A. When jack bean exts. are subjected to dialysis the bisphenoid crystals are pptd. first, the uncryst. spheroids sep. next and the needles are formed last. A partial sepn. can be made by filtering off the ppts. as they appear but it is better to make the sepn. by means of the NaCl solns. previously mentioned. After several repptns. the globulins give no Molisch test but may still contain P. A method is described in detail for the sepn. of the globulins and more data concerning them will be published later.

A. P. LOTHROP.

Globulin of the coconut, *Cocos nucifera*. I. Preparation of coconut globulin. Distribution of the basic nitrogen in coconut globulin. CARL O. JOHNS, A. J. FINKS AND C. E. F. GERSDORFF. U. S. Dept. Agr., Bur. Chem. *J. Biol. Chem.* 37, 149-53 (1919).—The principal protein of the endosperm of the coconut is a globulin containing the following % of the basic amino acids: cystine, 1.44; arginine, 15.92; histidine, 2.42; lysine, 5.80; tryptophan, present. The % of free amino N is equal to nearly  $\frac{1}{2}$  of the lysine N as detd. in the Van Slyke analysis. The globulin contains all the basic amino acids necessary for growth and maintenance and in nutrition expts. in which the coconut globulin was the only source of protein in the diet for a prolonged period normal growth was obtained. The results of the nutrition expts. will be published later and a com-

plete hydrolysis of the globulin is also in progress. A method which is not too laborious and time-consuming is described for the prepn. of large amts. of the globulin for use in nutrition and other expts.

A. P. LOTHROP.

**The physicochemical state of the proteins in cow milk.** LEROY S. PALMER AND ROBERT G. SCOTT. Univ. Mo. *J. Biol. Chem.* 37, 271-84(1919).—From a study of cow milk Van Slyke and Bosworth (*C. A.* 9, 1608) have drawn the conclusion "that the albumin of cow's milk is partly in true soln. and partly in suspension, the suspended portion being adsorbed by the casein when the milk is fresh but passing over into true soln. when the milk sours or when HCHO is added to prevent bacterial decompn." P. and S. have repeated and extended the expts. and have failed to confirm these conclusions. "Expts. are reported in which fresh skim milk, skim milk preserved with 5%  $\text{CHCl}_3$ , skim milk preserved with 0.05% HCHO, and the lactic acid whey from fresh skim milk were filtered through Pasteur-Chamberland filtering tubes under pressure. The total protein passing through the filters was detd. in each case by pptn. with Almen's tannic acid reagent, and the non-protein N was detd. in the filtrate from the ppt. thus formed. The amt. of non-casein protein recovered in the filtrate did not in any case exceed 10% of the non-casein protein in the original milk, and in most cases the amt. recovered was considerably less than this figure. There was also only a partial recovery of the non-protein N of the original milk in the expts. with chloroformed and HCHO-treated milk. These results are widely divergent from those reported by previous investigators. The variation in the size of the pores of different Pasteur-Chamberland filters which is indicated by a comparison of our data with those secured by others who have filtered milk through these filters shows conclusively the fallacy of drawing conclusions regarding the true state of soln. of non-casein proteins of milk based on filtration studies of this character." When milk preserved with  $\text{CHCl}_3$  is allowed to stand, the amt. of albumin recoverable by heat coagulation is markedly reduced when compared with the same milk analyzed perfectly fresh. The milk used by Van Slyke and Bosworth was preserved with 5%  $\text{CHCl}_3$  and its effect on reducing the amt. of albumin recoverable by heat coagulation was found in certain cases to be sufficiently great to account for their conclusions that a portion of the albumin is in true and a part in colloidal soln. "One expt. is reported indicating that this depression may be due partially to a pptn. of heat-coagulable protein by the  $\text{CHCl}_3$ . A plausible explanation is thereby offered for the results secured by other investigators who find that chloroformed milk apparently allows less heat-coagulable protein to pass through the Pasteur-Chamberland filter than milk preserved with HCHO or sour milk."

A. P. LOTHROP.

**The state of proteins in cow milk.** L. L. VAN SLYKE AND A. W. BOSWORTH. *J. Biol. Chem.* 37, 285-6(1919); cf. preceding abst.—Porous clay filters have the power of adsorbing some of the constituents of milk serum when it is passed through them and a certain vol. (50-75 cc. in the authors' expts.) must be passed through before const. compn. is attained. As Palmer and Scott used much finer filters, "had they discarded the first 100 cc. or so and then collected a total of 250 cc. or more from which to draw samples for analysis the results obtained by them would have more weight when used to criticize the results secured by us. With respect to their work on chloroformed milk we can only say that the action of  $\text{CHCl}_3$  upon the proteins of milk is a progressive one, due to two or more factors, one of which is the action of the HCl produced. After a few weeks the proteins may be completely pptd. from the milk. The changes noted by them at the end of 7 days are therefore not comparable to the changes which might have taken place in our filtrations lasting from 12 to 36 hrs."

A. P. LOTHROP.

**Amphoteric colloids. III. Chemical basis of the influence of acid upon the physical properties of gelatin.** JACQUES LOEB. *J. Gen. Physiology* 1, 363-85(1919); cf. *C. A.*

13, 326.—Gelatin was treated with an excess of HBr and the amt. of Br combined was detd. The curves showing the amt. of Br combined are approx. parallel with those for osmotic p., viscosity and swelling of the gelatin soln. Thus the curves for osmotic p. are a function of the number of gelatin-Br mols. formed. The influence of HBr on the physical properties of gelatin is due to the fact that gelatin is an amphoteric electrolyte, sparingly sol. in  $H_2O$  at the isoelectric point, but sol. when converted into a salt with a univalent anion like gelatin-Br. The curve for the bromine number (*i. e.*, the number of cc. of 0.01 *N* Br in combination with 0.25 g. gelatin) is parallel with that for osmotic p. Gelatin previously treated with HBr is free of Br at the isoelectric point ( $p_H = 4.7$ ) and on the more alkaline side from this point. On the acid side of the isoelectric point, gelatin is found in combination with Br, the bromine number increasing as the  $p_H$  rises. Titration with NaOH of gelatin previously treated with HBr results in the neutralization of the pure gelatin. This HBr is freed from the gelatin during the titration when the  $p_H = 4.7$ . A comparison of the  $p_H$  values and the bromine numbers shows that over 90% of the Br or HBr found is in combination with gelatin. It is emphasized that colloidal speculations not based on the laws of classical physical chemistry are not warranted.

CHAS. H. RICHARDSON.

## B. METHODS AND APPARATUS.

STANLEY R. BENEDICT.

Method for producing conductivity water suitable for water culture experiments.

R. B. HARVEY. *Bot. Gas.* 63, 323-4(1917).—The apparatus is entirely of glass, which therefore does away with the possibility of copper and other metals in the distillate, as is likely when any of the more recent types of water stills is used. B. HARROW.

New titration method for the determination of uric acid in urine. J. LUCIEN MORRIS. Washington Univ. and Univ. Ill. Med. Schools. *J. Biol. Chem.* 37, 231-8 (1919).—In the method described the uric acid is pptd. as the Zn salt, the amt. of which is detd. by titration with  $KMnO_4$  in a soln. alk. with  $NaHCO_3$ . The end point used is the blue starch iodide color and because of the mild nature of the oxidation and the excess iodide present there is no fading to confuse the end point. With normal urines the method gives results which are identical with the colorimetric method but with pathological urines there are some irregularities; the cause of which it has so far been impossible to det. Work is in progress on the adaptation of the method to the detn. of the uric acid in blood. Pipet 5 cc. of urine into a 50 or 100 cc. centrifuge tube and add 3 cc. of 10%  $ZnCl_2$  soln. and 25 cc. of  $H_2O$ . Mix with a stirring rod, put in a small piece of litmus paper and add enough 20%  $Na_2CO_3$  soln. with stirring to turn the litmus decidedly blue. Centrifuge for 2-3 min. to remove the heavy ppt. of  $ZnCO_3$ ,  $Zn_3(PO_4)_2$  and Zn urate. Carefully pour off the liquid from the ppt. which is sufficiently packed down to remain in the tube. Dissolve the ppt. with stirring in dil. HCl. To the acid soln. add 15 cc. of satd.  $Na_2HPO_4$  soln. and if necessary a few drops more of dil. HCl to dissolve a ppt. of  $Zn_3(PO_4)_2$ . Finally add 2 cc. of 3% U acetate soln. and while stirring again make alk. with  $Na_2CO_3$ . Centrifuge 2-3 min. and pour the liquid carefully into a 300 to 500 cc. Erlenmeyer flask for titration. None of the uric acid is pptd. in the large excess of phosphates and the Zn and U remove all substances which would interfere in the  $KMnO_4$  titration. Acidify the alk. soln. with HCl and add 25 cc. of 10%  $CaCl_2$  soln. and an excess of solid  $NaHCO_3$ .  $Ca_3(PO_4)_2$  will ppt. when the neutral point is reached but an excess of  $NaHCO_3$  beyond this point is desirable. Add 1 cc. of 10% KI soln., 3 cc. of 0.5% sol. starch soln. (starch will serve but sol. starch gives a better end-point) and enough distd.  $H_2O$  to make the vol. within a few cc. of 250 cc. Titrate with 0.002 *N*  $KMnO_4$  soln. until a blue shade spreads throughout the soln. The color of the drop of  $KMnO_4$  soln. as it hits the surface changes from pink to blue and assists in judging the approach of the end point. It is also an advan-

tage to compare the soln. from time to time with another awaiting titration or with a blank arranged for the purpose. A correction should be made for the amt. of free I necessary to show a perceptible blue color in 250 cc. This can easily be detd. by titrating a blank containing 1 cc. of 10% KI soln., 3 cc. of 0.5% sol. starch soln. and 250 cc. of distd.  $H_2O$ . It ordinarily amounts to 0.8 cc. and this figure should be subtracted from the observed reading. *Prepn. of standard  $KMnO_4$  soln.*: Make up a stock soln. containing 3.166 g. per l. (0.1 N) in the usual manner and keep it in a tightly stoppered amber-colored bottle. After the usual preliminary period, during which the value of the soln. decreases somewhat, the value remains as nearly const. as its use in the prepn. of 0.002 N solns. requires. Measure 10 cc. of the stock soln. into a 500 cc. flask and make up to the mark. Standardize against a standard uric acid-phosphate soln. (Benedict and Hitchcock, *C. A.* 9, 1626) by the titration method already described or standardize in one of the usual ways and calc. its equiv. value in uric acid calcd. on the basis of 1 cc. of 0.1 N  $KMnO_4$  soln. being equal to 7.5 or 7.22 mg. of uric acid. In M.'s experience, 1 cc. of  $KMnO_4$  soln. is equiv. to 7.32 mg. of uric acid when titrated in  $NaHCO_3$  soln.; 3 different 0.1 N stock solns. on diln. gave values of 0.14, 0.143 and 0.193 mg. per 1 cc. of 0.002 N soln. The dil.  $KMnO_4$  soln. will not keep its value longer than for a single day's work.

A. P. LOTHROP.

**Modifications of Benedict's and Folin's quantitative sugar methods.** HOWARD D. HASKINS. Univ. Oregon Med. School. *J. Biol. Chem.* 37, 303-4(1919).—It is possible to substitute  $NaSCN$  for  $KSCN$ , which is very difficult or impossible to obtain, in Benedict's and Folin's sugar reagents. In preparing Benedict's soln., dissolve the Na citrate first in 650 cc. of hot  $H_2O$ , then the monohydrated  $Na_2CO_3$ , and finally 105 g. of  $NaSCN$  (equiv. to 125 g. of  $KSCN$ ). Filter through cloth and add the  $CuSO_4$  soln. without waiting for it to cool. Titrations with urines are identical with the regular reagent and with the substitute. On substituting  $NaSCN$  in Folin's mixt. of salts (*C. A.* 12, 1059) the titration figures are distinctly too low. Correct titrations can be obtained by reducing the amt. of  $NaSCN$  and boiling half as long as directed by Folin (0.5, 1 and 1.5 min. instead of 1, 2 and 3). Both with slow titrations (6 to 8 portions of urine added) and with rapid titration (3 portions) the results were satisfactory. For each estn. use 4 g. of a salt mixt. containing 20 g. of  $NaSCN$ , 60 g. of dry  $Na_2CO_3$ , and 100 g. of  $Na_2HPO_4$ . A small flask is more convenient than a test tube for the analysis.

A. P. LOTHROP.

**The concentration of antitoxic sera.** ANNIE HOMER. *Proc. Physiol. Soc., J. Physiol.* 52, xxxi(1918).—Tricresol, a variable com. product, when used to adjust the reaction of sera preliminary to pptn. of proteins, has to be used in variable amts. C. F. phenol can be used successfully in concns. of 0.45 to 0.5%. H. prefers the preliminary adjustment of the reaction of the plasma to  $P_H$  8.3 to the use of either phenol or tricresol. Cf. *C. A.* 12, 1652, 2009.

J. F. LYMAN.

**Blood volume.** A method for its determination, with data for dogs, cats and rabbits. W. J. MEEK AND H. S. GASSER. *Am. J. Physiol.* 47, 302-17(1918).—A sample of blood is drawn to serve as a control. To 10 cc. of this freshly drawn blood 10 cc. of a 1.0% soln. of acacia are added and the acacia is detd. as furfuralphloroglucide by the method of Kröber (*J. Landw.* 48, 357). For each kg. of body wt. 4 cc. of a 20% acacia soln. (in 0.9% NaCl) are injected intravenously, and 15 mins. allowed for mixing in the body. A 10-cc. sample of blood is then drawn and the acacia in it is detd. as in the control. Blood vol. is calcd. by using the formula

$$\frac{20 \times \text{cc. of acacia}}{\text{blood vol. in cc.}} = \frac{\text{wt. of phloroglucide in blood sample}}{\text{wt. of phloroglucide in control}}$$

This vol. must be corrected for the difference between the amt. of blood drawn and

the acacia injected. While the amt. of phloroglucide obtained from a mixt. of acacia and blood is not as high as that from a  $H_2O$  soln. of acacia, still it is claimed that under all possible conditions the percentage recovery is approx. const. Acacia in the amts. recommended is harmless to animals and does not expand the blood vol. during the time necessary for a detn. By this method the blood vol. in the dog is 9.72%, in the cat 5.50%, and in the rabbit 5.44%, respectively, of the body wts. J. F. LYMAN.

Use of amyl alcohol in histological technic and especially in the Romanovskii method. A.-CH. HOLLANDE. *Compt. rend. soc. biol.* 81, 223-5(1918).—H. recommends the substitution of amyl alc. for abs. EtOH in histological technic. The stained sections are passed successively through pure amyl alc. (5-10 mins.), a mixt. of equal parts of amyl alc. and xylene, then through pure xylene (2 portions) in order to remove all traces of amyl alc., and are then mounted in xylene and Canada balsam. Amyl alc. has the advantage (over the  $Me_2CO$ -xylene mixts. of the Giemsa method) of not decolorizing preps. stained by the Romanovskii and derived (Giemsa, etc.) methods; even the most delicate tints are preserved. Amyl alc., even when kept in an open container, produces no turbidity with xylene and does not cause dimness of the preps., whereas the use of EtOH containing  $H_2O$  is subject to this objection.

H. S. PAINE.

Investigation, determination and excretion of arsenic in the urine. PAUL DURET. *Compt. rend. soc. biol.* 81, 736-7(1918).—Organic matter is first destroyed by action of  $NH_4$  persulfate in the presence of  $H_2SO_4$ . A qual. test for As is made by reducing the As compds. in this liquid with nascent H (Zn and  $H_2SO_4$ ) in a flask in the neck of which is inserted a filter paper impregnated with a 1:100 alc. soln. of  $HgCl_2$ ; the  $AsH_3$  evolved produces a yellow or brown color on contact with this paper. As is detd. quant. by placing the above liquid (after destruction of organic matter) in a Marsh app. and passing the  $AsH_3$  evolved into a  $HNO_3$  soln. of  $AgNO_3$ . The proportion of As in the original liquid is calcd. from the amt. of  $AgNO_3$  which is reduced, the amt. of  $AgNO_3$  reduced by a given wt. of As as  $AsH_3$  having been previously detd. In the case of syphilis patients who received successive injections of 0.30, 0.60, 0.75 and 0.90 g. of novarsenobenzol at 8-day intervals As appeared in the urine within 24 hrs. after the 1st injection. The capacity for renal elimination of As was not greater than 0.01 g. of As per 24 hrs. Each patient received injections of 2.55 g. of novarsenobenzol in all (slightly more than 0.50 g. of As) and during the 28 days of the expt. there was excreted in the urine approx. 0.10 g. of As or practically  $\frac{1}{8}$  of the amt. injected. No more As was eliminated in the urine 4 days after the last injection (0.90 g. of novarsenobenzol) than was excreted 4 days after the 1st injection (0.30 g. of novarsenobenzol).

H. S. PAINE.

Colorimetric determination of non-protein nitrogen of the blood by means of Nessler's reagent. A. GRIGAUT AND F. GUÉRIN. *Compt. rend. soc. biol.* 81, 1139-42 (1918).—G. and G. propose a method similar to the nesslerization method of Folin and Denis for detg. non-protein N in small amts. of blood, etc. Three to 5 cc. of serum, plasma, whole blood or erythrocytes are mixed with an equal vol. of 20:100  $CCl_4CO_2H$  and filtered after several mins. Two cc. of the filtrate, 1 cc. of  $H_2SO_4$ - $H_3PO_4$  mixt. (100 cc. 66° Bé.  $H_2SO_4$ , 300 cc. 60° Bé.  $H_3PO_4$ , 25 cc. 10:100  $CuSO_4$  soln.) and a piece of pumice stone are placed in a large test-tube and the non-protein N compds. are hydrolyzed by heating over a flame (certain precautions are prescribed); the total time required is about 5 mins. Allow the liquid to cool 2 mins., add distd.  $H_2O$ , transfer to a 100 cc. flask, dil. with distd.  $H_2O$  to 70-75 cc., add 13.5 cc. 10:100 NaOH soln. and 10 cc. Nessler reagent (containing 5-6:100 of  $HgI_2 \cdot 2KI$  and 3:100 of NaOH) and complete the vol. to 100 cc. with distd.  $H_2O$ . This soln. is compared colorimetrically with a standard soln. containing 0.8 cc.  $H_2SO_4$ - $H_3PO_4$  mixt., 13.5 cc. of 10:100 NaOH soln.

and (in normal cases) 25 cc.  $(\text{NH}_4)_2\text{SO}_4$  soln. in 100 cc. The  $(\text{NH}_4)_2\text{SO}_4$  soln. is prepd. by dissolving 4.716 g. pure  $(\text{NH}_4)_2\text{SO}_4$  in 1 l. of 0.2 N  $\text{H}_2\text{SO}_4$  soln. and dilg. 10 cc. of this soln. to 1 l.; it contains 0.01 mg. N per cc. Comparison of this method with the Kjeldahl procedure showed a variation of not more than 0.7 cg. per 1000 g. of material. This method may be adapted to the sp. detn. of protein, proteose, urea and  $\text{NH}_3$  N.

H. S. PAINE.

**Trypsin and a new method of purifying enzymes.** JOSEPH T. WOOD. *J. Soc. Chem. Ind.* 37, 313-57(1918).—W. repeated the expts. of Holzberg (cf. *C. A.* 7, 2233) by adding a 0.1% and also a satd. soln. of safranin to various infusions containing trypsin and subjecting the ppts. formed to the gelatin test. It is suggested that Holzberg removed some of the enzyme by washing the ppt. On repeating the expts. with a purer form of trypsin, containing but little albuminous matter, no ppt. was formed. Trypsin was purified by immersing disks of high-grade filter paper in the impure enzyme soln., then drying quickly in a current of hot air. When such paper is placed in water the enzyme dissolves in 15 to 20 min. to a clear soln. while the colloid matter adheres to the paper. It is not claimed that a pure enzyme is produced, but that about 35% of non-enzyme material has been removed from the original sample. The purified enzyme was inactive to polarized light.

L. W. RIGGS.

**Acidity of the urine.** E. AND E. PITTARELLI. *Revista critica di clinica medica* 19, 517 and 529(1918); *J. Am. Med. Assoc.* 72, 458.—The authors state that the acidity of the urine is not as simple as generally accepted. There are at least two acidities, one reacting to methyl orange and the other to phenolphthalein. The latter is const. but not the former. There is also a latent acidity which can be rendered evident by the addition of  $\text{HCHO}$ . The true acidity of the urine due to the free or semi-combined acids forms scarcely two-thirds of the acidity ordinarily estd. with litmus, etc. The other third is made up of salts of weak bases combined with weak acids. This proportion keeps quite const. and the true acidity of urine is always lower than the figures hitherto accepted as correct; it corresponds to an acid soln. N/30. To distinguish between real and apparent acidity equal vols. of urine are treated with  $\text{CaCl}_2$  to transform all of the phosphates to Ca salts. Phenolphthalein is added to one specimen and dimethylaminoazobenzene to the other and the specimens are made neutral with 0.1 N NaOH and 0.1 N HCl, resp. The alkali required for the first specimen corresponds to the sum of the free weak acids and the combined weak acids. The acid required for the second specimen corresponds to the weak bases combined with the weak acids and therefore also to these weak acids transformed into salts. The difference between the vols. of NaOH and HCl used corresponds to the free acids.

L. W. RIGGS.

**Preparations of mediums: new hydrogen-ion concentration method.** LYMAN J. STRONG. U. S. Army. *J. Am. Med. Assoc.* 72, 413(1919).—The methods of adjusting mediums to the alkalinity of the human tissues are discussed and objections stated to the various indicators employed. Phenolsulfonephthalein as an indicator has a fairly long end-point which is of the same alkalinity as the tissues, and has proved so reliable that other methods have been discarded. But two stock mediums are necessary, one fluid broth, the other solid agar. "Broth is prepd. from 1000 g. of minced lean beef and 1000 cc. of water which are infused in an ice box for 24 hrs., filtered through glass wool, heated to boiling 2 min. and again filtered through glass wool. Now are added peptone 10 g., NaCl 5 g., water up to 1000 cc. and the white of one egg. The mixt. is heated to a boil and filtered through glass wool until clear; a 1 cc. ampule of phenolsulfonephthalein is then added. About 5 cc. are poured into each of two test-tubes. To one test-tube a drop of any acid soln. is added; to the other a drop of NaOH soln. Then drop by drop are added HCl or NaOH until the color of about 5 cc. poured into a third

tube is between the color of the other two tubes. The H-ion concn. of the entire batch of medium will now be about  $p_H = 7.5$ . This is the same as that of av. human blood serum. Should a ppt. form it may be filtered again through glass wool." "The advantages of the methods are: No standard soln. is used; any soln. will do. Any tube that changes reaction can be told at a glance and discarded before inoculating. Growth always produces a change in color. Growth of all organisms is much faster and luxuriant. Much time is saved and there is a more desirable product." L. W. RIGGS.

**Action of ferric thiocyanate upon normal human serum.** ARTHUR VERNES AND ROGER DOURIS. *Compt. rend.* 167, 972-4 (1918); cf. *C. A.* 12, 915, 2009.—The reagent is prepd. by adding 0.25 g.  $NH_4CNS$  to 4 cc. of a soln. containing 20 cc. of  $FeCl_3$  soln., sp. gr. 1.26, and 150 cc. water, and the mixt. is made up to 250 cc. with water. In a series of 20 small tubes is distributed normal serum in amts. ranging from 0.4 down to 0.04 cc., each tube containing 0.1 less than the preceding and the vol. of the serum is made constant (0.4 cc.) by the addition of water. To each tube is added 0.8 cc. of the reagent. The reaction assumes a periodic character, and after agitation no ppt. is seen in the tubes containing the more concd. serum but appears in the following tubes, reaching a max. in about the tenth tube and decreasing to no ppt. in the tubes containing the most highly dild. serum. There is an accompanying decoloration which facilitates observation. The ppt. in the middle tubes is whitish, gelatinous and with certain serums remains in the tube on inversion of the latter. The results obtained in this study form a basis for comparison in the study of syphilitic and other abnormal serums.

L. W. RIGGS.

**Necessity for rapid estimation of the total acidity of gastric juice.** MAURIN. *Rept. pharm.* 29, 1-2 (1919).—Expts. showed that in gastric juice containing 1.65 per 1000 of total acidity at the time of evacuation, on standing the acidity increased as follows: 6 hrs., 1.94; 24 hrs., 2.18; 36 hrs., 2.34; 48 hrs., 2.56 parts per 1000. After 48 hrs. the acidity tends to diminish. The importance of an immediate detn. of the acidity for diagnostic purposes is evident, especially in cases of hypoacidity.

L. W. RIGGS.

## C. BACTERIOLOGY.

**Habituation of staphylococci to antiseptics in vitro and in vivo.** G. S. HARDE AND H. W. JACKSON. *Compt. rend. soc. biol.* 81, 635-7 (1918).—Strains of staphylococci freshly isolated from wounds (before treatment of the latter) were subjected to the action of 0.5:100 PhOH for 3 periods of  $1\frac{1}{4}$  hr. each and subsequently to the action of 1:100 PhOH for 3 periods of  $\frac{3}{4}$  hr. each, the bacteria being kept in culture between each treatment. The treated cultures resisted the action of 1:100 PhOH for  $1\frac{1}{2}$  hr., while the original, untreated cultures only resisted for  $\frac{3}{4}$  hr. On the other hand, staphylococci showed hypersensitiveness to Carrel-Dakin  $NaClO$  soln. after repeated contact with the latter. Staphylococci isolated from wounds which had been treated with Carrel-Dakin soln. for 24-55 days were subjected in culture to the action of different proportions of this antiseptic. Staphylococci isolated from wounds which had been treated 45, 52 and 55 days with Carrel-Dakin soln. were practically as sensitive to the antiseptic as those which were isolated from 2-day wounds (more sensitive in 1 instance). Unusual resistance (ascribed to individual peculiarities) was encountered in staphylococci in 2 instances (from 2- and 33-day wounds, resp.).

H. S. PAINE.

**Oxidation of lactic acid by bacteria with formation of pyruvic acid and ketone compounds.** P. MAZÉ. *Compt. rend. soc. biol.* 81, 1150-2 (1918).—M. reports the amts. of pyruvic acid produced at  $25^\circ$  in 4, 9, 16 and 32 days by 6 species of bacteria growing in a medium composed of a soln. of inorganic salts (cf. *C. A.* 11, 976, 2585) which was slightly alk. to phenolphthalein and to which 3 g. of Ca lactate per 100 cc. had been added. Pyruvic acid was detd. by a colorimetric method based on the Simon

reaction; preliminary distn. under reduced pressure was not required. This colorimetric method was applicable to detn. of pyruvic acid in concns. varying from 0.1:1000 to 1:1000. The rate of formation of pyruvic acid and the rate of its subsequent destruction varied greatly according to the species of bacteria concerned. The max. proportion of pyruvic acid observed was 5.020 g. per l. of culture. The amt. of lactic acid destroyed in 32 days varied from 0.24 g. to 7.26 g. per l., according to the species of bacteria; the amt. of AcOH produced in 32 days varied from traces to 2.280 g. per l. Formic acid was not encountered. In addition to pyruvic acid and AcOH 2 of the species of bacteria produced acetylmethylcarbinol and diacetyl while a 3rd species produced acetylmethylcarbinol but no diacetyl; the other 3 species produced only traces of these compds. Acetylmethylcarbinol is apparently produced by combined reaction and oxidation of lactic and pyruvic acids while diacetyl is doubtless formed by oxidation of pyruvic acid alone. It is also possible that diacetyl is formed directly from acetylmethylcarbinol by oxidation of the CHOH group, although this supposition is weakened by the absence of butyleneglycol (only traces of which were found in the cultures).

H. S. PAINE.

**Action of bile on dysentery bacilli.** S. MARBAIS. *Compt. rend. soc. biol.* 81, 1136-7(1918).—Disappearance of dysentery bacilli from the stools of patients was observed to coincide with the flow of bile to the intestinal canal. M. has, therefore, made expts. *in vitro* to det. whether bile exerts an injurious effect on dysentery bacilli. Ox bile heated at 120° was inoculated with a no. of strains of Shiga, Hiss and Flexner bacilli; after a certain period at 37° approx. 1 cc. of the bile was used to inoculate bouillon and gelose. Even 48 hrs. contact with bile failed to prevent growth of the Hiss and Flexner bacilli. Seven out of 14 strains of Shiga bacilli failed to yield a culture after contact with bile.

H. S. PAINE.

**New culture bouillon which is particularly suited to the development of pyogenic streptococcus.** LOUIS BOYER. *Compt. rend. soc. biol.* 81, 229-31(1918).—In view of the unusually abundant growth of pyogenic streptococcus in osseous tissue and bone marrow as shown by its persistence in infected fractures B. added org. and inorg. constituents of bone tissue to a no. of culture broths in an attempt to obtain a culture medium peculiarly suited to this bacillus; none of these were, however, distinctly superior to the usual media. Excellent results were finally obtained with a medium prepd. in the following manner: A mixt. of 500 g. crushed bones (preferably beef ribs), 100 cc. N HCl and 900 cc. H<sub>2</sub>O is allowed to stand 12-24 hrs., heated at 125-30° for 1½ hr., cooled, and filtered through cloth; peptone (15:1000) is added, the soln. is neutralized (without filtering) with dil. NaOH soln. to amphoteric reaction, heated at 125-30° for 1½ hr. and filtered while hot. The prepn. is kept in a cool place for 1 day to induce pptn. of Ca<sub>3</sub>HPO<sub>4</sub>; it is then filtered, distributed in tubes and sterilized at 120°. The hemolyzing power of the cultures was used as a criterion for detg. the suitability of the various media studied. The medium above-mentioned is also suitable for other bacteria constituting the aerobic flora of war wounds.

H. S. PAINE.

**Biochemical action of bacteria on sugars and alcohols.** A. BESSON, A. RANQUE AND CH. SENEZ. *Compt. rend. soc. biol.* 81, 930-3(1918).—The varying results which have been obtained with respect to the action of certain bacteria on sugars are due largely to the varying character of the media in which the sugars were incorporated. An attempt has been made to standardize the technic so that comparable results may be obtained. The authors have studied the action of the typhoid bacillus, *B. proteus*, *B. coli*, the cholera vibrio, paratyphoid A and B bacilli, pyocyanic bacillus and the Shiga, Flexner and Hiss bacilli on glucose, levulose, maltose, sucrose, lactose, dulcitol, mannitol and glycerol incorporated in (1) litmus and peptone gelose with meat bouillon and (2) 3:100 aq. peptone soln. The media contained 1.5 % of sugar or alc. Results were

noted after 24-48 hrs. incubation. *B. coli*, *B. proteus*, the paratyphoid A and B bacilli and the cholera vibrio attacked or failed to attack the 3 alcs. according to the medium in which the latter were incorporated. The data obtained warrant the following conclusions. The nature of the culture medium is of great importance and should be indicated whenever the action of bacteria on sugars and alcs. is reported. Glucose is the most readily attacked of the 8 compds. studied. No bacillus was found which attacked other sugars and alcs. and failed to attack glucose. Bacteria may attack sugars and polyatomic alcs. in 2 ways., *vis.*, (1) by decompn. into simpler compds. with formation of organic acids and without production of gas; (2) by production of both acids and gas ( $\text{CO}_2$ , H and small amts. of hydrocarbons). These 2 modes of attack are a sp. property of the bacillus and do not depend on the nature of the sugar or alc. A bacillus which attacks a sugar or alc. without formation of gas also acts in the same manner on all the sugars and alcs. which it attacks. A bacillus which attacks a sugar or alc. with evolution of gas likewise acts with formation of gas on all sugars and alcs. which it attacks. The fact that a bacillus attacks sugars with or without formation of gas is more important for fixing the character of the bacillus than mere detn. of the fact that the latter attacks certain sugars. Bacilli may be classified into 3 fundamental groups according to the following facts: (1) no action on sugars and alcs.; (2) attack without production of gas; (3) attack with production of gas. Commenting on the above, L. Martin points out that the use of an aq. meat ext. would not furnish a sufficiently definite medium for incorporation of sugars and alcs., since very fresh meat contains glycogen which may subsequently be transformed into glucose, thus introducing a complicating factor.

H. S. PAINE.

**Action of *Bacillus sporogenes* on certain carbohydrates and proteins of culture media.** E. VAUCHER AND F. GUÉRIN. *Compt. rend. soc. biol.* 81, 362-4(1918).—Various sugars and polyatomic alcs. were added to a medium prepd. by beating 2 egg whites in 330 cc.  $\text{H}_2\text{O}$ , adding 4 cc. of *N* NaOH soln., heating at  $95^\circ$  for  $1\frac{1}{2}$  hr., filtering and sterilizing. The sugars were added in the proportion of 1:100 and the cultures were examd. 24 hrs. after inoculation. All cultures were made in exhausted sealed tubes. Concordant results were obtained with all races studied. Glucose, levulose and maltose were attacked; this reaction was particularly distinct and rapid with glucose and maltose. Levulose was sometimes attacked more slowly by certain races of *B. sporogenes*; the resulting acidity was in general less when levulose was used. Lactose, sucrose and mannitol were never attacked; in the presence of these sugars the medium remained alk., even after several days. In all cases the pptn. or non-pptn. of albumin (due to production of acid) was a certain and sufficient index for detg. whether the sugar studied was or was not attacked. A 2nd medium was also employed; this was prepd. by finely mincing a beef heart (carefully freed from fat), adding an equal wt. of  $\text{H}_2\text{O}$ , heating at  $90^\circ$  for 1 hr., and rendering slightly alk. to litmus with NaOH. The proteolytic action of *B. sporogenes* on both the foregoing media was studied. These media contained before inoculation a certain proportion of syntonins and albumoses, but no trace of peptone. After inoculation there was a progressive decrease in syntonins and a parallel increase in peptones. This transformation was complete in 8-10 days and at the end of this period the protein substances of the medium consisted solely of peptones. Degradation of proteins followed the same course in both media.

H. S. PAINE.

**Study of vitamines utilizable in the culture of bacteria.** Application to the bacillus of influenza (*B. de Pfeiffer*). H. AGULHON AND R. LÉGROUX. *Compt. rend.* 167, 597-600(1918).—The idea of vitamines, hormones of growth, has been extended to microbiology by recent workers. The favoring action of blood, serum, ascitic fluid, etc., upon bacterial cultures is accounted for by the presence of vitamines of growth in

these liquids and not by the introduction of intact albumin into the cultures. To prep. exts. of the blood rich in vitamins the defibrinated blood was pptd. with four vols. abs. alc. which was allowed to remain in contact 30 min. and then removed by the centrifuge or filter. The ppt. was taken up with a vol. of physiol. saline soln. equal to that of the alc. used, allowed contact for one hr. with agitation, then filtered or centrifuged. These operations were made aseptically or the soln. was passed through the Chamberland F bougie. The soln. thus obtained is nearly colorless and is rich in vitamins. In a second method the defibrinated blood was treated with four vols. physiol. saline, heated 15 min. on the water bath at 80° with frequent agitation and filtered or centrifuged as in the first method. Solns. of vitamins obtained by either of these methods, when added to the usual culture media in amts. of 5 to 10%, promote the growth of *B. de Pfeiffer*. Even a 1% soln. showed positive results. Expts. seemed to prove that the vitamins are fixed in the cells and a destruction of these elements by alc., heat or otherwise sets them free in the aqueous liquid. They are probably insol. in alc. A cold alc. ext. of freshly washed cells was inactive, but when made at 80° was slightly active. Cold or warm acetone exts. were inactive. Heat to 80° in the presence of alc. or acetone followed by desiccation at a lower temp. did not destroy the vitamins, as they could be extd. with water from the powders thus obtained. Aqueous solns. of vitamins lose a part of their activity by heating 15 min. at 90°. This activity is more stable if the vitamins are in a gelose medium when a decrease is noted at 100° and total disappearance at 120°.

L. W. RIGGS.

Production of non-specific bactericidal substances by means of antistaphylococcic and antistreptococcic vaccines in vivo and in vitro. A. E. WRIGHT. *Compt. rend.* 167, 600-6(1918).—Nine vols. of human blood were dild. with one vol. physiol. salt soln. and one vol. staphylococcic vaccine. After 2.5 hrs. in the thermostat the serum of the blood was tested by inoculating with progressive dilns. of a staphylococcic or streptococcic mixt., and 12 to 14 hrs. later the results together with those of suitable controls were examd. microscopically. The expts. were repeated with varying periods of incubation and the results assembled in five tables. The expts. show that by a direct addition of vaccine of extravascular blood, a non-specific bactericidal substance may be produced. This depends primarily on the amt. of vaccine employed, also on the duration of incubation. The phenomena observed *in vitro* are largely paralleled and confirmed by expts. *in vivo*.

L. W. RIGGS.

Production of glycine by *Isaria densa*. MARIN MOLLIARD. *Compt. rend.* 167, 786-8(1918).—Old cultures of various bacteria or fungi on gelatin media frequently show groups of crystals. This is especially marked with cultures of *Isaria densa*. Upon sepn. and purification these crystals melted at 236° and gave several positive reactions for glycine including Sorensen's test in which the acidity was compared with that of an equal wt. of known glycine. Expts. proved that this action is not at all comparable to an acid or tryptic hydrolysis of protein material. If cultures of *I. densa* are grown on a medium containing sugar, the necessary minerals, and gelatin as the only nitrogenous constituent, there is a rapid development of the fungus, a progressive liquefaction of the gelatin, and at the end of 6 months, when the culture does not appear to undergo further modification, a large mass of crystals remains. These may be purified by fractional pptn. from alc. and yield 33% of the gelatin introduced. Hydrolysis of gelatin by acids yields only 16.5%. Fibrin, which gives 15% as leucine and 3% as glycine upon acid hydrolysis, yields 38% of glycine under the action of the mycelium of *I. densa*. Egg albumin, serum albumin and casein do not give glycine upon acid hydrolysis, but under the action of *I. densa* they yield 35, 30, and 32%, resp., of glycine. Parallel expts. with *Penicillium glaucum* gave no glycine with gelatin, egg albumin, or casein. With serum albumin no excess of crystals of glycine over acid

hydrolysis was produced, but crystals of leucine were formed. It is suggested that the culture of *I. densa* on gelatin be used as a method for the prepn. of glycine.

L. W. RIGGS.

Influence of certain conditions upon the comparative consumption of glucose and of levulose by *Sterigmatocystis nigra* on splitting of sucrose. MARIN MOLLIARD. *Compt. rend.* 167, 1043-6(1918).—The culture liquid employed consisted of sucrose 46.7 g.;  $(\text{NH}_4)_2\text{C}_4\text{H}_4\text{O}_6$ , 9.2;  $\text{MgSO}_4$ , 0.8;  $\text{KH}_2\text{PO}_4$ , 0.8;  $\text{FeSO}_4$ , 0.046;  $\text{ZnSO}_4$ , 0.046;  $\text{H}_2\text{O}$  up to 1000 cc. The quantity of N in the culture medium was such that the  $\text{NH}_4$  and sugar disappeared from the liquid in the same time and the ratio of N to C was 1 to 16. If the ratio of consumption of the two sugars in this liquid is measured during the course of growth, it is seen that glucose is used much faster at first, but its use rapidly decreases and the two sugars co-exist up to their complete utilization. The wt. of dry mycelium obtained from 150 cc. of the nutritive medium was about 4 g. If the  $(\text{NH}_4)_2\text{C}_4\text{H}_4\text{O}_6$  was replaced by  $\text{NH}_4\text{NO}_3$  or by  $\text{NH}_4\text{Cl}$ , still keeping the ratio of N to C 1 to 16, similar results were obtained. In case of  $\text{NH}_4\text{Cl}$  with the ratio of N to C 1 to 32 the yield was 2.9 g. of mycelium in 4 days instead of 4 g. in 3 days. Upon adding varying amts. of HCl (e. g., 290 or 310 mg.) to 150 cc. of the nutritive liquid the consumption of glucose was increased, ranging from 2.39 to 6.97 times that of levulose. All the glucose had disappeared on the 21st day, while more than half of the levulose remained. The results of this study appear to support the ideas of Lindet (cf. *C. A.* 5, 2664) that levulose contributes principally to the formation of tissue.

CARL L. ALSBERG.

Hardening process in plants and developments from frost injury. R. B. HARVEY. Bur. Plant Industry, U. S. Dept. Agr. *J. Agr. Research* 15, 83-113(1918).—Cabbage plants kept at  $+3^\circ$  for 5 days were resistant to freezing when kept at  $-3^\circ$  for 5 hrs. and were found to have an increased  $P_H$  and an increase in salt concn. although neither of these factors was sufficient to account for the lower f. p. There was also an increase in amino N which would indicate that the proteins have undergone a change rendering them more difficult to ppt. Upon freezing, the juices of "non-hardened" cabbage were found to have the protein more completely pptd. than was the case with the juice of "hardened" cabbage, and the  $P_H$  of the former was also higher. The tumors resulting from freezing also contained juice which exhibited a higher  $P_H$ . R. N. HARGER.

Contributions to our knowledge of plant sterols. I. The sterol content of wheat (*Triticum sativum*). M. T. ELLIS. *Physiol. Lab., Univ. London. Biochem. J.* 12, 160-172(1918); cf. *C. A.* 12, 2614.—The phytosterols in different organs of wheat plant were examd. The chief phytosterol present in the grain—sitosterol—was found to be the same as that in the embryo. Bran contains a phytosterol, but its m. p. differs from that of sitosterol. With vegetative organs an alc.,  $\text{C}_{26}\text{H}_{48}\text{O}$ , which did not give the phytosterol color reactions, and did not combine with digitonin, and an oil were isolated. The quantity of phytosterol in normal wheat plant is greater than that in the grain. In the embryo the percentage of phytosterol is greater than in the plant.

II. Occurrence of phytosterol in some of the lower plants. *Ibid* 12, 173-7(1918).—Ergosterol and fongisterol were isolated from the fungus *Polyporus nigricans*. The evidence tends to show that in lower plants the sterols may occur in non-cryst. form.

B. HARROW.

Blister canker of apple trees; a physiological and chemical study. DEAN H. ROSE. *Bot. Gaz.* 67, 105-46(1919).—This is a continuation by R. of an earlier investigation on the oxidase activity of healthy and diseased bark (*C. A.* 9, 2396). The oxidase ac-

tivity of diseased bark is greater than that of healthy bark. H-ion concn. of diseased bark ( $P_n = 5.61$ ) is less than that of healthy bark (5.15). In general, the more severely the bark is attacked by the fungus the greater is its catalase activity. The catalase activity is to some extent in indirect ratio to oxidase activity. B. H.

**The sulfur requirement of the red clover plant.** W. E. TOTTINGHAM. Univ. Wis. *J. Biol. Chem.* 36, 429-37(1918).—A study was made of the response of the common red clover plant to different forms and planes of S supply; the seedlings were grown in  $H_2O$  cultures using Knop's nutrient soln. and in sand cultures irrigated with a renewed nutrient soln. "For these exptl. conditions, between 0.1 and 0.01 of the usual amt. of  $MgSO_4$  of Knop's soln. was as efficient as the usual amt. for the growth of red clover, when the balance of the  $MgSO_4$  was replaced by  $Mg(NO_3)_2$ . The yield of dry tops of this plant was only  $1/4$  to  $2/3$  as great with  $MgSO_4$  wholly replaced by  $Mg(NO_3)_2$ , as with unmodified Knop's soln. Addition of  $Na_2SO_4$  and  $CaSO_4$  to the S-free modification of Knop's soln., in amts. equiv. to the S of the unmodified soln., produced yields of dry tops superior to those of the latter soln. In this respect  $CaSO_4$  was very efficient. In view of the fact that all of the nutrient media which supplied S were liberally supplied with Ca, it appears that  $CaSO_4$  had peculiar efficiency as a mol. complex, and that the S of this salt functioned in the mol. combination in which it was supplied. The more or less parallel fluctuations of the plane of S supply, wt. of N assimilated, and yield of dry tops, of these clover plants, indicate that a deficiency of S supply restricted growth by limiting the synthesis of protein." A. P. LOTHROP.

**Do seedlings reduce nitrates?** J. DAVIDSON. U. S. Dept. Agr., Bur. Chem. *J. Biol. Chem.* 37, 143-8(1919).—Growing seedlings do not, as a part of their metabolic processes, reduce the nitrates in the medium in which they are growing. Positive results reported by previous investigators were no doubt obtained because of insufficient precautions to guard against bacterial contamination. A. P. LOTHROP.

**The withering of pitch-firs (Epicea) in the valley of the Arve (Chedde and Chamonix).** MANGIN, VINCEY, HALLER AND HENNEGUY. *Compt. rend. acad. agr.* 5, 113-5(1919).—A discussion. At Chedde this phenomenon is due to HCl formed from Cl liberated in the manuf. of chlorates and perchlorates. The zone of the action of noxious gases and fumes from Paris includes the forest of Boulogne, which accounts for the withering of the pitch-firs here as these trees are extremely sensitive. This zone is clearly limited by the disappearance of mosses and lichens from the trunk of trees. Cf. following abstr. ALBERT R. MERZ.

**The withering of the pitch-firs (Epicea) in the valley of the Arve (Chedde and Chamonix).** L. MANGIN. *Compt. rend. acad. agr.* 5, 195-204(1919).—In the region of Chamonix this is a physiological disease of uncertain origin though probably due to lack of atm. humidity. Cf. preceding abstract. ALBERT R. MERZ.

**Linaria (L. minor Desf.) containing hydrocyanic acid.** MÉDÉRIC GARD. *Compt. rend. soc. biol.* 81, 621-2(1918).—G. has detected a cyanogenetic compd. in *Linaria minor* Desf. by the usual method of maceration, digestion and distn.; 100 g. of the fresh plant contained 0.0583 g. HCN (detn. by Liebig-Denigès method) as compared with 0.0147 g. in the same wt. of *L. striata* D. C. (found by Bourquelot). Plants in full bloom were used for the analysis. H. S. PAINÉ.

**The physiological basis of morphological polarity in regeneration.** I. JACQUES LOEB. *J. Gen. Physiology* 1, 337-62(1919); cf. *C. A.* 12, 1206, 2343.—The two apical leaves of the plant, *Bryophyllum calycinum*, suppress shoot formation in all the dormant buds situated basally from them. Each apical leaf suppresses shoot formation in that half of the stem to which its petiole is attached. When one-half of the petiole of such a leaf is removed, the growth of basal buds in one quadrant of the stem is suppressed.

This inhibitory action of a leaf is diminished or disappears when the mass of the leaf is reduced below a certain limit. When stems are suspended horizontally, the inhibitory influence of an apical leaf is greater when the leaf is on the upper than when it is on the lower side of the stem. It is suggested that the leaf secretes a substance having an inhibitory influence upon shoot formation and that this substance is carried by the sap from the leaf towards the base of the stem. An apical leaf accelerates root formation in the basal part of a stem, the effect increasing with the mass of the leaf. The influences of the leaf upon shoot and root formation are factors determining the polar character of regeneration.

CHAS. H. RICHARDSON.

A comparative study of permeability in plants. W. J. V. OSTERHOUT. *J. Gen. Physiology* 1, 299-304 (1919).—Quant. studies on the permeability of the algae, *Laminaria*, *Ulva*, *Rhodomenia*, and of a flowering plant *Zostera*, showed a marked agreement in all cases. Permeability was measured by detg. the elec. resistance of the plant tissues in solns. of NaCl, CaCl<sub>2</sub>, BaCl<sub>2</sub>, SrCl<sub>2</sub>, MnCl<sub>2</sub>, NiCl<sub>2</sub>, (K<sub>2</sub>SO<sub>4</sub>.Al<sub>2</sub>(SO<sub>4</sub>)<sub>2</sub>.24H<sub>2</sub>O), Ce(NO<sub>3</sub>)<sub>3</sub>, La(NO<sub>3</sub>)<sub>3</sub>, Et<sub>2</sub>O, CHCl<sub>3</sub>, EtOH or in combinations of them.

CHAS. H. RICHARDSON.

Relation of the plant to the reaction of the nutrient solution. D. R. HOAGLAND. Calif. Exp. Sta. *Science* 48, 422-5 (1918).—Previous expts. with barley seedlings (cf. *C. A.* 11, 2819) grown in various potassium phosphate solns. indicated a strong tendency on the part of the plant to change either acid or alk. culture media in the direction of neutrality. Extension of these expts. was made by growing barley to maturity in other solns., including complete nutrient solns., observations being made at all stages of growth. Also several varieties of beans were grown. Sand and water cultures were used, the technic being such as to insure normal well matured plants. Even with plants grown to maturity without change of soln., the neutral reaction remained constant throughout the entire period. H-ion concn. was usually detd. as described by Clark and Lubs (cf. *C. A.* 11, 1443, 3288). Chem. analysis of the solns. proved that the change in reaction had been the result of selective absorption from the various phosphoric anions accompanied by an equiv. removal of positive ions. Barley plants grown 7 weeks in favorable nutrient solns. were transferred (after thoroughly washing the roots with distd. water) to solns. of KCl, K<sub>2</sub>SO<sub>4</sub>, MgSO<sub>4</sub>, K<sub>3</sub>PO<sub>4</sub>, NH<sub>4</sub>Cl and NaNO<sub>3</sub>. The reactions of the solns. were tested after periods of contact varying from a few hrs. to 40 days. In no case was excessive H- or OH-ion concn. produced. The change in the K<sub>3</sub>PO<sub>4</sub> soln. was striking in that from an intense alkalinity the soln. became approx. neutral. NH<sub>4</sub>Cl soln. retained an acid reaction. Analysis showed a considerable absorption of both ions but about 5% more NH<sub>4</sub> than Cl was removed. The balance was restored by the excretion from the plant of equiv. quantities of other bases, chiefly Ca. After boiling, the NaNO<sub>3</sub> soln. gave an OH-ion concn. similar to that produced by the hydrolysis of Na<sub>2</sub>CO<sub>3</sub>. Apparently part of the NO<sub>3</sub> was removed simultaneously with an equiv. quantity of Na but more NO<sub>3</sub> than Na was absorbed, HCO<sub>3</sub> ion entering or being formed in the soln. to restore the balance. This ion in equil. with dissolved CO<sub>2</sub> brought about a neutral reaction in the soln. actually in contact with the plant. From KCl solns. K and Cl were absorbed in equiv. quantities. A study of Calif. peat soils showed them to be decidedly acid yet containing from 100 to 3000 p. p. m. NO<sub>3</sub> (basis of dry soil). The acidity did not interfere with the production of good crops of beans, potatoes and corn, nor with the production of nitrates.

L. W. RIGGS.

Mitochondrial origin of the plastids. A. GUILLIERMOND. *Compt. rend.* 167, 430-5 (1918).—This paper presents a discussion of the theory, supported by Rudolph, Scherrer, and Sapehin, and which has recently been advanced by Mottier, that the plastids are formed independently of the mitochondria. G. maintains that the plastids

proceeding from the differentiation of mitochondria are identical with those of the animal cell. This conclusion is sustained by the recent comparative studies of Cowdry upon the chondriome of the pea root and of the pancreas of mice. L. W. RIGGS.

**Distribution of mineral elements and of nitrogen in etiolized plants.** G. ANDRÉ. *Compt. rend.* 167, 1004-6(1918); cf. Maquenne and Demoussy, *C. A.* 11, 2817, 2922. —One hundred and eleven seeds of white haricot, weighing 130 g., were planted on July 5 in a darkened bed of Fontainebleau sand which had been previously treated with acids, water and heat. The bed was watered daily. On July 30 the etiolized plants were in good condition with no trace of moldiness and with a length of stems from 30 to 35 cm. The plants were removed, the roots washed, and the cotyledons sepd. from the roots and stems. The wts. of 100 fresh seeds, cotyledons, roots and stems were 117.1, 97.0, and 346.84 g., resp., and on drying each at 110° the percentages of water were 13.81, 67.50, and 88.89, resp. The distribution and translocation of various elements, as detd. by chem. analysis, are shown in the following table:

|                         | N.<br>g. | CaO.<br>g. | MgO.<br>g. | K <sub>2</sub> O.<br>g. | P <sub>2</sub> O <sub>5</sub> .<br>g. | SO <sub>3</sub> .<br>g. |

**Mineral metabolism in experimental acidosis.** KINGO GOTO. Rockefeller Inst. *J. Biol. Chem.* 36, 355-76(1918).—The effect of prolonged administration of acid on the mineral compn. of bones and muscles and on the excretion of phosphates in the urine has been studied. Rabbits were used rather than dogs because they form  $\text{NH}_3$  much less rapidly than dogs and would therefore be expected to neutralize unusual amts. of strong acid only by means of the reserves of alkali in the body fluids, tissues and skeleton. From 25 to 75 cc. of 0.25 *N* HCl were administered daily for 1 to 4 weeks; most of the rabbits showed a poor resistance to HCl and died usually within 1 to 2 weeks if more than 25 to 30 cc. were given. A reduction in the plasma bicarbonate occurred accompanied by an increased phosphate excretion which in some cases was followed by a fall. The phosphate excretion in the feces was not decreased. There was a marked loss of P and K by the muscles and a less marked decrease in Na. The chief effect on the skeleton was a great reduction in the fat content, from 17.1 to 8.6% of the dry wt. The skeletons of the acid-fed rabbits also averaged about 10% lighter than the control animals but there was no demonstrable loss of  $\text{Ca}_3(\text{PO}_4)_2$ . A definite loss of about 20% of the  $\text{CO}_2$  indicated that  $\text{CaCO}_3$  is more readily sacrificed in acid intoxication than  $\text{Ca}_3(\text{PO}_4)_2$ . "The individual variations in muscle and bone are such that in every constituent detd. the figures for some of the acid-fed rabbits overlap the normal range. Consequently the interpretation of results is not so sharp as could be desired. The results, nevertheless, indicate with a fair degree of decisiveness that next to the bicarbonate of the body fluids, the first major reserves of alkali drawn upon in acid intoxication of rabbits are the alk. phosphates, particularly K phosphate of the muscles, and

the  $\text{CaCO}_3$  of the bones. The results are only suggestive in their relationship to clinical acidosis. Whether the loss of alk. phosphates from the tissues and  $\text{CaCO}_3$  from the bones occurs in the latter remains to be ascertained by accurate detn. of mineral balances."

A. P. LOTHROP.

**Studies in the metabolic changes induced by the administration of guanidine bases.** V. The change of phosphate and calcium content in serum in guanidine tetany and the relation between the calcium content and sugar in the blood. C. K. WATANABE. Yale Med. School. *J. Biol. Chem.* 36, 531-46(1918); cf. *C. A.* 12, 2017. —The normal content of phosphate in normal rabbits is from 2 to 4 mg. per 100 cc. of serum, the amt. varying with the condition, the environment and the food of the animal. An amt. above 4 mg. indicates a condition of acidosis. After injection of guanidine hydrochloride an increase occurs in almost all cases, reaching as high as 5 times the normal amt. The normal Ca content of rabbit blood varies from 11 to 13 mg. per 100 cc.; it usually decreases in guanidine tetany; the decrease is not as marked as is the increase in phosphate. Under normal conditions the ratio of Ca to phosphate varies from 5.7 to 1.9, but decreases after guanidine injection to 2.8 to 0.5. The change of phosphate and Ca is not distinctly parallel, the phosphate change being the preliminary change and the Ca decrease or restoration a secondary phenomenon following acidosis. After injections of large doses of guanidine a hypoglycemia and an increased phosphate content are observed with or without a diminution of Ca in the same samples of blood. When small doses are injected at intervals there is no change in the sugar content even when the Ca is diminished to  $\frac{1}{2}$  the normal value. The low Ca is accompanied by a high phosphate content. These facts would indicate "that Ca is not concerned in the direct control of carbohydrate metabolism in guanidine poisoning but that some other intermediary metabolic change plays a part in this phenomenon. The hypoglycemia is accompanied by acidosis." The condition of severe acidosis with retention of phosphates, a decrease of Ca in the blood and a hypoglycemia are observed in parathyroid tetany as well as in guanidine tetany and the symptoms and all other physiological conditions are similar in both types. Large increases in guanidine bases have been found in parathyroid and idiopathic tetany and "it is possible that the fundamental cause of tetany is the increased formation of guanidine N brought about by the disturbance of the function of the parathyroid." The injection of sol. Ca salts temporarily relieves the tetany by replacing the Ca of the tissues and blood which has been inactivated or pptd. and excreted, and thereby reduces the excitability of the nerves. The mechanism for bringing about the diminution of the Ca in the blood and tissues may be attributed to the acidosis.

A. P. LOTHROP.

**Study of the metabolism in multiple exostoses.** VERNON K. KRIEBLE AND OLAF BRUGEM. Jefferson Med. College and McGill Univ. *J. Biol. Chem.* 37, 179-85 (1919).—A metabolic study was made of a case of multiple exostoses in which there were a number of bony growths on the lower ends of the radius and ulna and on the inner sides of the ankles, also a thickening of the digits with a tendency to dislocation due to atrophy of ligaments. There is apparently no relation between this disorder and rickets, nor is it due to any primary disturbance of general metabolism. There was a loss of N due in part, at least, to a hypermotility of the intestine as the patient was also suffering from a gastrointestinal disturbance. Retention of S was attributed to storage in the growing cartilage. The retentions of P, Ca and Mg were within normal limits as were also the % excretions of these elements in the urine.

A. P. LOTHROP.

**Creatinuria and acidosis.** W. DENIS AND A. S. MINOT. Mass. General Hosp. *J. Biol. Chem.* 37, 245-52(1919).—Although D. has obtained evidence in favor of the protein theory of creatine origin and has shown that the amt. of creatine present in

urine can be increased or decreased at will by changes in the protein content of the diet, it seemed desirable to carry out on human subjects a few expts. on the influence of acidosis along the same general lines used by Underhill (*C. A.* 10, 3096) in work on rabbits. It was found impossible to administer HCl to human subjects in amts. sufficiently large to make the expts. in any way comparable to those of Underhill so that a reverse procedure was adopted in which the subjects were fed a highly acid diet, and after creatine excretion was established  $\text{NaHCO}_3$  was administered in amts. sufficient to keep the urine alk. to litmus. The subjects were 2 normal boys, 2 normal women and 4 women suffering from hyperthyroidism. "On the whole the exptl. results presented appear to demonstrate no definite connection between changes in acid-base equil. and creatine excretion in human beings." In Underhill's work with rabbits creatine excretion was produced by a highly acid diet and decreased to the vanishing point in a diet of an alk. nature; administration of HCl promptly brought about creatine excretion, which continued as long as the acid administration was kept up. A. P. LOTHEROP.

ANDREW HUNTER.

The role of the thymus in pediatrics. MURRAY B. GORDON. *Endocrinology* 2, 405-19(1919).—An "unprejudiced review" with bibliography covering "the past few years." E. J. C.

Researches on the genesis of thiocyanic acid in animals. V. Influence of feeding on the elimination of urinary thiocyanic acid in the dog. SERAFINO DEZANI. Univ. Torino. *Arch. farm. sper.* 25, 278-88(1918); cf. *C. A.* 12, 2091.—The elimination of urinary HCNS depends upon the nature of the food. On changing from a food poor in N to one rich in N, the urinary HCNS is doubled in 24 hrs. Increasing the amt. of purines or their precursors in the food, however, had little or no effect. The formation of HCNS from HCN liberated from nitriles ingested is not a function of the kidney. A. W. DOX.

The newest "hormone." SWALE VINCENT. Winnipeg. *Endocrinology* 2, 420-9 (1918).—The depressor activity of exts. of lymphatic glands as found by P. Marfor (*Sur la fonction hormonique des ganglions lymphatiques. Arch. Ital. d. Biol. (Pisa)* 68, 113-27(1918)) is no evidence of the elaboration of a "hormone" and does not justify the use by M. of the term "lymphogangline" as applied to the active principle in the exts., which "it is to be hoped will not find any place in the literature." F. S. HAMMETT.

Galactischia: the hypodermic injection of mother's milk as a galactagogue. J. H. WILMS. *J. Am. Inst. Homeopathy* 11, 884(1919).—An abundant secretion of milk was produced by several successive injections hypodermically of small amts. (3 to 15 minims) of her own milk into a mother who was secreting practically no milk. JOSEPH S. HERBURN.

Contribution to the physiology of phosphorus and calcium metabolism as related to milk secretion. EDWARD B. MEIGS, N. R. BLATHERWICK AND C. A. CARY. U. S. Dept. Agr., Bur. Animal Ind. *J. Biol. Chem.* 37, 1-75(1919).—A study has been made of the concn. of certain substances in the blood, particularly P and Ca, but also other constituents, in an endeavor to discover the precursors in the blood of the various constituents of milk. The blood and plasma analyzed were obtained from the jugular or from the abdominal subcutaneous vein of intact normal or nearly normal cattle, the samples being obtained by means of a small trochar and cannula inserted through the skin into the vein. "Normal blood plasma contains no phosphorized proteins, and probably no P compds. at all except phosphatides and inorg. phosphates. The P of these two classes of compds. certainly comprizes more than 97% of all that exists in

normal plasma. The precursor in plasma of milk fat and milk P is phosphatide—either lecithin or some related body. The concn. of Ca in the plasma of cows is almost const. Small variations can be induced by varying the amt. supplied with the rations, but the chief controlling factor is probably the concn. of bicarbonate in the plasma. It is probable that the concn. of Ca tends to vary inversely with that of the bicarbonate. The concns. of phosphatide and of inorg. phosphates in the plasma are highly variable. Both can be made to vary by changing the amt. of P supplied with the rations, though the variations induced in this manner show themselves most markedly in the inorg. phosphate. Both undergo variations as the accompaniment of increasing age and of the later stages of pregnancy. The phosphatide of the plasma shows a marked tendency to rise during the 1st month of lactation and to remain high until lactation has ceased. This phenomenon is largely independent of the diet, and is thought to be connected with the fact that near the beginning of lactation there is a tendency for the body fat to be released from its stores and thrown out into the blood." From the results of their own expts. and the work of other investigators, the authors have formulated the following hypotheses regarding P and fat metabolism "though they cannot yet be regarded as definitely established." P from the digestive tract reaches the general circulation only in the form of inorg. phosphate and the phosphatides are synthesized from this inorg. phosphate and triglycerides. All org. P compds. are manufactured within the cells in which they are found and phosphorized proteins are not transported by the plasma from one fixed cell in the body to another. Many of the tissues and organs of the body of which the mammary gland and the muscles are conspicuous examples can receive their fat and P from the blood only in the form of phosphatide.

A. P. LOTHROP.

The physical properties and chemical composition of human amniotic fluid. DOKO UYENO. Kyoto Imp. Univ. *J. Biol. Chem.* 37, 77-103(1919).—Amniotic fluid from women in labor was obtained by a procedure which practically precluded contamination. It is a slimy, yellowish white or pale yellow fluid, cloudy like soap water and has a peculiar odor. It almost always contains much mucus and was filtered through four-fold gauze and later with suction before being used in the expts. Sp. gr. 1.0078 (av. 23 specimens); f. p. ( $\Delta$ ) 0.46 to 0.565°, av. 0.504°; osmotic pressure, 5.536 to 6.8, av. 6.072 amts.; sp. elec. cond., 119.06 to  $134 \times 10^{-4}$ , av.  $127.15 \times 10^{-4}$ ; H ion concn.,  $0.2266 \times 10^{-8}$  to  $0.2648 \times 10^{-7}$ , av.  $0.1282 \times 10^{-7}$ ; reaction, slightly alk.; it is nearly optically inactive after removal of the albumin by coagulation. The fluid always contains Cl, CO<sub>3</sub>, SO<sub>4</sub>, PO<sub>4</sub>, Na, K, Ca, Mg and Fe. The amts. of Cl, PO<sub>4</sub>, K, Na, Ca, and Fe are nearly const. The amt. of NaCl averages 75.2% of the total ash. A part of the H<sub>2</sub>SO<sub>4</sub> in the ash comes from the S of the albumins and a very small amt. is in the form of ethereal sulfates. The amt. of sulfates in the ash is therefore dependent on the amt. of albumin in the fluid. *D*-Lactic acid is a const. constituent and varied in 10 cases from 0.0336 to 0.1355%, av. 0.0726%. The fluid is sugar-free. It was impossible to demonstrate the presence of purine bases, choline, or monoamino-acids, even when 3000 cc. of amniotic fluid were examd. Histidine, lysine and allantoin are present in very small amts., but the presence of arginine is uncertain. Coagulable albumins are always present (av. 0.226% including mucin) and globulin occurs in traces. The amt. of mucin is too small to be quant. detd. Peptones and albumoses are absent. The av. amt. of NH<sub>3</sub> is 0.0029%, and of urea, 0.0323%, both making up about 70% of the so-called rest N. Uric acid and creatine are present in very small amts., but no creatinine or hippuric acid was found. Cholesterol is obtained on extrn. with Et<sub>2</sub>O.

A. P. LOTHROP.

Urea formation by the placenta. FREDERICK S. HAMMETT. Harvard Med. School. *J. Biol. Chem.* 37, 105-12(1919).—Urea increases in amt. from day to day

in a watery suspension of pulped placenta tissue kept in glass bottles in the presence of  $\text{CHCl}_3$  and  $\text{C}_7\text{H}_8$ . "The processes leading up to this product are in question. It may be simply a splitting of the urea residue from arginase, or it may be a heightening to determinability of the usual processes taking place in extrauterine life, whose course from deaminization, through  $\text{NH}_4$  carbamate, to urea, is fairly well established. Whatever the source of the urea formed by placenta tissue, these results give evidence that this organ as well as being excretory in function is also actively concerned in the prep. of the nitrogenous by-products of the fetus for excretion. It is our present idea that the fetus is able only faintly, if at all, to perform for, of, or by itself the functions of prep. its nourishment in assimilable form, or of breaking down its by-products into compds. ready for excretion; and that the placenta is interposed between mother and fetus to remove as far as possible these extra burdens from the maternal organism. These questions can obviously be settled only by continuation of the study of the biochemistry of placenta and fetal tissues."

A. P. LOTHROP.

**Comparative distribution of urea, creatinine, uric acid, and sugar in the blood and spinal fluid.** VICTOR C. MYERS AND MORRIS S. FINE. N. Y. Post-Graduate Medical School and Hosp. *J. Biol. Chem.* 37, 239-44(1919).—"Comparative analyses of blood and spinal fluid are reported on 15 cases, showing varying degrees of N retention. The concn. of urea in the spinal fluid averaged 88% of that of the blood, the concn. of creatinine 46%, that of uric acid 5%, and that of sugar 57%. These % differences represent the order of their soly. in  $\text{H}_2\text{O}$ , and apparently also the order of their diffusibility through the various tissues and membranes."

A. P. LOTHROP.

**Antitoxic action of the liver with respect to blood sera and uremic sera in particular.** HENRI BÉNARD AND RENÉ PANNIER. *Compt. rend. soc. biol.* 81, 628-30(1918).—Sera of patients with uremia, arteriosclerosis and aortitis (urea content of the blood = 0.27-4.17 g. per l.) were injected into (1) the marginal vein of the ear and (2) one of the mesenteric veins of rabbits at the rate of 1 cc. per min. until death ensued; the vol. of serum per kg. wt. of animal required in (2) was 1.6-4.6 times greater than that required in (1). The antitoxic action of the liver was also shown *in vitro* by injecting into the marginal vein of the ear of rabbits (1) the natural toxic serum, (2) the toxic serum after 1 hr. contact with  $\frac{1}{2}$  of its wt. of macerated rabbit kidney and (3) the toxic serum after 1 hr. contact with  $\frac{1}{2}$  of its wt. of macerated rabbit liver. The vol. of serum required to produce death was greater for (3) than for (2) and greater as a rule for (2) than for (1). The results show that the liver exercises a pronounced antitoxic action with respect to the toxic substances of blood serum and especially with respect to those of uremic serum.

H. S. PAINE.

**Parathyroids and calcium metabolism.** EDUARD UHLENHUTH. *J. Gen. Physiology* 1, 315-22(1919).—The thymus gland excretes a tetany-producing substance which is antagonized by the parathyroids. In parathyroidectomized mammals or in salamander larvae (which do not possess parathyroids) this substance may reduce the Ca content of the organism; it also has a highly injurious effect on the central nervous system resulting in permanent spasmodic muscular contraction and paralysis of almost the entire muscular system. The muscular contractions were prevented in these expts. by the introduction of Ca and Mg salts (as lactates) into the body, but nothing was found which would antagonize the tetany toxin and thus prevent the lesions of the central nervous system. The most important function of the parathyroids is to prevent tetany toxin from reaching the central nervous system by antagonizing it.

CHAS. H. RICHARDSON.

**Study of the pigments of blood serum.** G. PATEIN. *J. pharm. chim.* 18, 225-38 (1918).—P. reviews the methods of Gmelin-Hayem for the detection of biliary pigments in blood serum, and the procedure adopted by Gilbert, Herscher and Posternak

(1903), then Grimbirt's, finally Fouchet's methods (*C. A.* 12, 916). He extends the latter by sepg. the blue ppt. after 30 min. exposure to air, by centrifuging and washing with 10 cc. of 0.6% NaCl soln. in which it is insol. The blue ppt. yields part of its color to a 95% EtOH-CHCl<sub>3</sub> mixt., the less so, the more prolonged the contact with the reagent. It is sol. in Na<sub>2</sub>CO<sub>3</sub>; after filtering off Fe(OH)<sub>3</sub>, HCl causes a gray-blue ppt. In oxidizing bilirubin in CHCl<sub>3</sub> soln. by dil HNO<sub>3</sub> (1:4) P. holds the characteristic blue color by sepg. the blue CHCl<sub>3</sub> soln. from HNO<sub>3</sub>, stirring with dil. Na<sub>2</sub>CO<sub>3</sub> soln. and acidifying with CCl<sub>3</sub>CO<sub>2</sub>H. With amyl alc. in place of CHCl<sub>3</sub>, oxidation stops at biliverdin regardless of duration of contact, even at higher concn. of the acid. Under conditions under which the tests for bile pigments are carried out, indoxyl and indole if present do not interfere. P. also finds in blood serum very small amts. of a new *blue pigment, acetoglobulin*. To obtain it, dil. 100 cc. of human blood to 1 l., then add AcOH drop by drop until distinctly acid to litmus. After several hrs. sep. by centrifuging. A sediment is formed of blue tint, insol. in H<sub>2</sub>O, EtOH, Et<sub>2</sub>O, CHCl<sub>3</sub>. Centrifuged with 0.6% NaCl soln. The blue color dissolves and the residue is white. The blue liquid forms a white coagulum and a colorless liquid at 60 to 80°. Two vols. of 90% EtOH ppt. the blue liquid with blue insol. color; the liquid is colorless.

### G. PATHOLOGY.

H. GIDEON WELLS AND ANDREW HUNTER.

**Diet as a preventive of cancer.** H. L. NORTHERP. *Hahnemannian Monthly* 54, 34-41(1919).—A discussion of the relation of the mineral content of the diet to the causation and prevention of cancer.

JOSEPH S. HEPBURN.

**Anaphylaxis and its relations to some diatheses common to infancy and childhood.** FREDERICK W. SCHLUTZ AND W. P. LARSON. *Univ. Minn. Arch. Pediatrics* 35, 705-13(1918).—Blood (3 to 5 cc.) was drawn from the patient, permitted to clot, and centrifuged; the vol. of serum obtained was approx. one-half that of the blood taken. The serum was injected intravenously or intraperitoneally into guinea-pigs of 250 to 300 grams body wt.; no ill effects were thereby produced, as a rule. Twenty-four hours later from 0.1 to 1.0 cc. of milk was injected into each animal, usually intraperitoneally, at times intravenously. The milk produced marked anaphylactic phenomena in the animals which had received blood serum from patients (aged from 8 months to 3 years) who were suffering from inflammatory exudative diathesis. The results indicated that definite anaphylaxis to foreign protein exists in this disease, and that the majority of the phenomena occurring during the disease are truly anaphylactic. When this technic was applied to cases of periodic vomiting of children (age of patients, over 4 years), similar phenomena occurred in several, but not all, the cases; expts. with this disease, and with both marasmus and milk overfeeding (children between 3 and 12 months of age) indicated that the anaphylactic reaction is not as clear cut with these diseases as with inflammatory exudative diathesis.

JOSEPH S. HEPBURN.

**Mantoux reaction in children.** OSCAR REISS. *Arch. Pediatrics* 35, 714-7(1918).—The Mantoux intracutaneous test was applied to 120 children—age from 3 days to 14 years—0.005 mg. of old tuberculin in normal saline being administered, and normal saline being used as a control. For comparison, the von Pirquet test was also applied; the latter test was never positive in the absence of a positive Mantoux reaction, but was negative in 3 cases which gave a positive Mantoux reaction. The intracutaneous test apparently was somewhat more reliable than the von Pirquet test. A positive Mantoux reaction must present a central papule at least 0.2 by 0.4 cm. in dimension with a surrounding areola; the normal saline control reveals the sensitivity of the skin. Repeated tests of 4 cases of tuberculous meningitis uniformly gave negative results; apparently these cases do not respond to cutaneous tuberculin tests.

J. S. H.

**Method of Vernes for sero-diagnosis of syphilis.** ROGER DOURIS AND ROBERT BRICQ. Lab. Syphilography, Ministry of the Interior, Paris. *Bull. soc. chim.* 23, 472-8(1918).—The reagents used are sheep erythrocytes, pig serum, and a colloidal suspension of perethynol. The sheep corpuscles are obtained from defibrinated blood, and are washed with the aid of centrifugation until the supernatant liquid is colorless; the wash soln. is slightly hypertonic, containing 9.5 g. NaCl, 0.15 g. NaHCO<sub>3</sub>, 0.42 g. KCl, 0.125 g. CaCl<sub>2</sub> in 1 l. of soln.; if the corpuscles tend to hemolyze, this phenomenon is prevented by doubling the concn. of the CaCl<sub>2</sub> in the soln. The sediment of erythrocytes is mixed with an equal vol. of the wash soln. Six portions (0.025, 0.050, 0.075, 0.100, 0.125, and 0.150 cc.) of the resulting suspension are dild. with distd. H<sub>2</sub>O, so that the final vol. of each is 2.6 cc. The colors obtained are compared with the color scale of Vernes. By successive approximations is detd. the vol. of suspension required to yield 8 on the color scale. This vol. is dild. to 0.8 cc. before use, and contains the standard amt. of red cells. The pig serum is standardized by use of 12 successive portions, ranging from 0.025 to 0.300 cc., the increment being 0.025 cc.; each portion is dild. to a vol. of 1.6 cc. with 0.9% NaCl soln., mixed with the standard amt. and vol. of erythrocytes, and incubated for 25 min. at 37°. A control expt. without serum is also made (no hemolysis). This titration is repeated with the serum dild. 1:4 with 0.9% NaCl soln., using successive portions of dild. serum from 0.200 to 0.675 cc.; the increment is 0.025 cc.; the details are as before. After incubation, the solns. are centrifuged; and the vol. of serum required for total hemolysis is detd.; it generally is from 0.130 to 0.150 cc. This standard amt. of serum is dild. to a vol. of 0.2 cc. before use by addition of pig serum which has been rendered non-hemolytic by heating for 30 min. at 55°. The perethynol is prepd. from ground, fresh horse heart by dehydration with 95% alc., drying at 37° for 15 to 20 hrs., grinding to a fine powder, extn. with ethylene perchloride, boiling at 115-121°, drying at 37°, and finally extn. with abs. alc. This final abs. alc. soln. is adjusted so that it contains 15 g. of solids per l., and then forms perethynol. This soln. is run in a fine stream into 40-fold its vol. of 0.9% NaCl soln., while agitating the latter. The resulting colloidal suspension is the reagent. Blood is drawn from the patient's vein; the serum is centrifuged, then heated for 20 min. at 55°. In the detn. proper, 0.2 cc. of human serum, 0.8 cc. of perethynol reagent, and the standard amt. and vol. (0.8 cc.) of pig serum are mixed; in the chief control, the perethynol is replaced with 0.9% NaCl soln.; after incubation for 75 min. at 37°, the standard amt. and vol. (0.8 cc.) of erythrocyte suspension is added to each, and incubation is continued for 20 to 30 min. The solns. are then centrifuged, and the degree of hemolysis is detd. by comparison with the color scale. Control expts. are also made on the reagents: (1) perethynol, serum, and erythrocytes, (2) serum and erythrocytes, (3) erythrocytes alone. In all 4 controls, the reading should be 8 on the color scale. In the detn. proper, a normal serum reads 8 on the color scale, while syphilitic sera give either partial or no hemolysis, and have syphilometric indices (color scale readings) from 0 to less than 8. Cerebrospinal fluid may be drawn by lumbar puncture, and tested without preliminary heating, using 1.6 cc. of the fluid; the pig serum is not dild. to its standard vol.; the technic otherwise is as for blood serum. The index should be detd. frequently on the same patient, and plotted on a curve; a single detn. has merely a transient value, showing the intensity of the infection at the time of the detn.; the curve throws light on the nature and course of the infection and its resistance to treatment. Cf. C. A. 13, 459.

JOSEPH S. HEPBURN.

**The influence of menstruation on acidosis in diabetes mellitus.** GEORGE A. HARROP, JR. AND HERMAN O. MOSENTHAL. Johns Hopkins Hosp. *Bull. Johns Hopkins Hosp.* 29, 161-3(1918).—In the case reported menstruation was accompanied by an increase in acidosis. The glucosuria and N elimination were both much in-

creased and permanent damage was done to the carbohydrate metabolism as the symptoms became more marked with each successive period until fatal coma occurred. "This is not a common sequence of events, but may possibly be regarded as an indication that diabetic patients should be closely observed during the menstrual period." A. P. L.

**Presence of complement in the blood stream.** RENÉ BÉNARD. *Compt. rend. soc. biol.* 81, 240-1(1918).—In view of the resemblance between complement and enzymes B. has attempted to ascertain whether complement exists in the blood as such or as a zymogen. Freshly drawn blood was mixed with  $\frac{1}{2}$  its vol. of isotonic oxalate soln. (0.28 g.  $K_2C_2O_4$ , 0.45 g. NaCl, 100 g. distd.  $H_2O$ ) and centrifuged. Complement fixation was studied as in the usual Wassermann reaction, the isotonic oxalate soln. being used instead of physiol. NaCl soln. and the proportion of oxalated plasma being doubled so as to correspond to the amt. of serum ordinarily employed. The results indicate that: (1) the oxalate soln. does not prevent hemolysis with guinea pig complement; (2) no hemolysis occurs with oxalate soln. in the presence of erythrocytes and hemolytic serum and in the absence of oxalated plasma; (3) oxalated plasma contains complement. B. concludes that complement exists preformed in the blood stream and not as a zymogen. H. S. PAINE.

**Persistence of reducing power of the cerebrospinal fluid in cerebromeningeal infections of traumatic origin.** MESTREZAT, WEISSENBACH AND BOUTTIER. *Compt. rend. soc. biol.* 81, 655-7(1918).—In a no. of cases of cerebromeningeal infection with fatal issue following cranial traumatism the reducing power of the cerebrospinal fluid not only persisted but was, in the majority of cases, greater than normal. It is possible that bacterial consumption of sugar was masked by an afflux of reducing substances liberated by decompn. of elements of the blood and nerve tissue. The value of the reducing power of the cerebrospinal fluid cannot in general be regarded as a criterion of the presence or absence of infection. H. S. PAINE.

**Absence in syphilitic serum of immunizing substances with action against icterohemorrhagic virus.** S. COSTA AND J. TROISIER. *Compt. rend. soc. biol.* 81, 165-7(1918).—The serum of syphilis patients (untreated, recent, secondary syphilis—treated syphilis of long standing—treated syphilis of very long standing—doubtful syphilis with positive Bordet-Wassermann reaction) was injected into guinea pigs together with active icterohemorrhagic virus. Icterus followed by death ensued in practically all cases. C. and T. had previously obtained a positive complement fixation reaction in icterohemorrhagic spirochetosis with both syphilitic and spirochetic antigen, while Martin and Pettit had obtained positive results with syphilitic serum in the presence of spirochetic antigen. H. S. PAINE.

**Bacteria present in complications of grippe; attempts at curative antistreptococcic hetero-vaccination.** J. GATE AND M. DECHOSAL. *Compt. rend. soc. biol.* 81, 1245-7(1918).—Treatment with an antistreptococcic vaccine gave distinctly positive results in cases where streptococcic infection was manifest. The Pfeiffer bacillus was only encountered once in sputa and not at all in blood cultures and pleural liquids. Pneumococci were found in a considerable no. of instances. In some cases no characteristic pathogenic agent was found in the sputa. H. S. PAINE.

**Hyperalbuminosis of the cerebrospinal fluid in traumatism of the cranium.** LECÈRE, MESTREZAT AND BOUTTIER. *Compt. rend. soc. biol.* 81, 597-600(1918).—Study of a considerable no. of various types of serious traumatisms of the cranium (in wounded soldiers) showed that hyperalbuminosis of the cerebrospinal fluid was the most characteristic reactional criterion of the gravity of the lesions produced; more or less pronounced hyperalbuminosis was usually observed without decrease in chloride or sugar content and without any marked accompanying cytological reaction.

Favorable evolution of the traumatism was associated with albumin contents little, if any, greater than 0.50 g. per l. Values of 1.0 g. or more per l. were almost always observed in cases with fatal issue; this was true regardless of whether the occurrence of hyperalbuminosis was sudden or gradual. In certain cases with fatal issue in which aseptis had not been maintained albumin contents of 4.50-4.60 g. per l. were attained. Hyperalbuminosis in the case of serious traumatism of the cranium (contusion, fracture or even wounds of the brain) appears to be due less to localized lesions (produced directly by the projectile, etc.) than to an extended reactional process associated with production of lesions due to shock.

H. S. PAINE.

**Cases of acute alveolar pyorrhea treated with neosalvarsan.** B. KRICHEVSKII. *Compt. rend. soc. biol.* 81, 620-1(1918).—*Sp. buccalis* predominated in the flora of the secretions. Intravenous injections of 10-30 cg. neosalvarsan in the severe cases and local instillations of a 1:100 glycerol soln. of neosalvarsan in the mild cases caused practically complete disappearance of the spirochetes and amelioration of the symptoms in the patients (soldiers).

H. S. PAINE.

**Serodiagnosis of syphilis; precipitation methods and nature of the Wassermann reaction.** M. RUBINSTEIN AND A. RADOSAVLJEVICH. *Compt. rend. soc. biol.* 81, 1145-7(1918).—Pptn. phenomena were studied by mixing human serum in the usual amt. (0.2 cc.) with syphilitic antigen (0.3 cc.) in a total vol. of 2 cc. (addition of distd. H<sub>2</sub>O), keeping the mixt. 1 hr. at 37° (Wassermann) or 0° (Jacobsthal) and centrifuging. Fresh, unheated, normal or syphilitic sera (without addition of antigen) were pptd. by distd. H<sub>2</sub>O under these conditions; a ppt. was rarely obtained with heated sera. An abundant ppt. was always produced in the presence of antigen in the case of both normal and syphilitic sera, these sera having been previously inactivated (30 mins. at 56°) or used without being heated. It was impossible to differentiate syphilitic from non-syphilitic sera either by the amt. of ppt. produced or by treatment of the ppt. with physiol. NaCl soln. The ppt. obtained by action of serum and antigen was dissolved by physiol. NaCl soln. with production of slight turbidity. This dissolved ppt. fixed complement in a sp. manner in the case of heated sera and in a const., non-sp. manner in the case of unheated sera. The globulin ppt. from unheated sera (0.2 cc. serum + 1.8 cc. distd. H<sub>2</sub>O), when dissolved in physiol. NaCl soln., often (but not constantly) fixed complement; addition of antigen always rendered the reaction positive, even with the globulins of non-syphilitic sera. It is therefore possible in the above manner to isolate a complex (heated serum + antigen) which fixes complement specifically. The supernatant liquid from the ppt. obtained by centrifuging was clear and limpid, while the antigen alone, when dild. and centrifuged, retained its original degree of turbidity; the complex which inactivates complement appears to be composed of a heavier "mol." produced by union of serum and antigen. The liquid, when freed from this sp. complex and rendered isotonic, showed no regularity in its ability to fix complement. Most of the reactions were studied in parallel at 37° and 0° owing to the fact that globulins are more readily pptd. at lower than at higher temps. When 0.2 cc. of serum was mixed with increasing (3-10) vols. of distd. H<sub>2</sub>O pptn. was considerably more pronounced at 0° than at 37°; the physical appearance of the ppt. was also different at the 2 temps. This increased pptn. of globulins at 0° probably explains why a positive Jacobsthal reaction may be obtained in cases (especially syphilis of long standing) in which the Wassermann reaction is negative. It is also probable that the globulins of the sera of syphilis of long standing are both qual. and quant. different from those of sera of recent syphilis, thus in some instances causing a ppt. at a lower and not at a higher temp. (a difference is also observed between heated and unheated sera).

## H. PHARMACOLOGY.

ALFRED N. RICHARDS.

**Milk secretion and carbohydrates injected subcutaneously.** UBALDO SAMMARTINO. Univ. Rome. *Arch. farm. sper.* 25, 146-60, 213-24, 257-77, 353-73(1918).—Injection of sucrose in large doses inhibits, while in smaller doses it stimulates milk secretion. The sucrose treatment was found useful in cases of both hyper- and hypogalactia.

A. W. DOX.

**Gastritis from asphyxiating gases.** UBALDO SAMMARTINO. Univ. Rome. *Arch. farm. sper.* 25, 300-20(1918).—Guinea pigs killed by exposure to phosgene and bromine developed lesions of the esophagus and stomach as follows: phosgene—hyperemia, hypersecretion, edema, severe swelling, cellular necrosis; bromine—ischemia, hypersecretion, dehydration, cellular necrosis, complete destruction.

A. W. DOX.

**Myrtol poisoning; with comments upon the toxicity of eucalyptus oil and myrtol in human beings and in animals.** LEWELLYS F. BARKER AND LEONARD G. ROWNTREE. Johns Hopkins Hosp. and Univ. *Bull. Johns Hopkins Hosp.* 29, 215-21(1918).—"Derivatives of plants belonging to the natural order *Myrtaceae*, and especially oil of eucalyptus and myrtol, may in large doses cause profound intoxication. In certain persons there is an idiosyncrasy, the symptoms of intoxication occurring after minute or therapeutic doses. The intoxication may affect chiefly the nervous system or chiefly the skin; in some persons, nervous and cutaneous manifestations are simultaneously observable. Recovery occurs in most instances, though several fatalities following eucalyptus poisoning have been reported. The symptoms of intoxication of the nervous system observed in man can be reproduced in animals by subcutaneous and by intraperitoneal administration of myrtol."

A. P. LOTHROP.

**Dakin's solution and Dakin's oil in the normal peritoneal cavity of the dog.** ERNEST G. GREY. Johns Hopkins Hosp. *Bull. Johns Hopkins Hosp.* 29, 221-3(1918).—"Both the neutral soln. of chlorinated soda (Dakin's soln.) and dichloramine-T in chlorinated paraffin (Dakin's oil), when injected into the normal peritoneal cavity of a dog, lead to an inflammatory reaction, the degree of which is directly proportional to the amt. of Cl antiseptic used. With a sufficient quantity (less of the oil suffices) death ensues. When either of the Cl antiseptics is injected into the gall-bladder of a dog no abnormal symptoms appear. Following the injection of the oil, however, the gall-bladder becomes thickened and shrunken, though the remainder of the biliary tract shows no discernible changes. A small amt. of Dakin's oil, when injected into the normal pleural cavity of an unanesthetized dog, may lead to a rapid (reflex?) death. Since Dakin's oil particularly has been used without recognizable ill effects in certain infections of the abdominal cavity, the results from the expts. outlined suggest that the wall of an abscess cavity or sinus must play an important part in protecting the peritoneum in general from the effects of the free Cl. They also suggest that the maintenance of an adequate drainage tract is an indispensable part of the technic for using

antiseptics of this nature within the abdomen. Until more evidence is at hand, then, both of the Cl antiseptics should be used in intra-abdominal infections with caution and certainly only in carefully selected cases."

A. P. LOTHROP.

**Behavior of Sudan III in the animal organism.** B. E. READ. Yale Univ. *J. Biol. Chem.* 37, 121-35(1919).—"The original purpose of the present expts. was to reinvestigate the seemingly contradictory statements with regard to the path of elimination of the fat-sol. dye Sudan III, and particularly the contention of Salant and Bengis (*C. A.* 10, 2935) regarding the excretion of Sudan III by the kidneys. The products of various manufacturers were used and gave varying results, which led to interesting observations on the doubtful purity of preps. of Sudan III obtainable on the market at present. Expts. made with the purified product, on the other hand, gave definite results, thus showing the need of careful examn. of all preps. of Sudan III used in scientific work to guarantee its purity before drawing conclusions supposedly based upon its properties as a pure, neutral, fat-sol. dye." The dye may be purified by dissolving it in alc. or glacial AcOH and pptg. it in H<sub>2</sub>O to remove all H<sub>2</sub>O-sol. substances. This process should be repeated and gives a fine brick-red powder of low m. p. (120-130°) similar to that of the com. article. It should then be recrystd. 3 or more times out of hot glacial AcOH and the purity of the fine, sheeny, flocculent, green-brown crystals, judged by the m. p., 195°. Very impure products must be dissolved in a lipid solvent and shaken out with dil. aq. alk. and acid alternately until the aq. solvent ceases to take up any further color. When dissolved in oil and administered intraperitoneally, subcutaneously or by mouth, Sudan III is absorbed and may be traced in the lymph, blood and bile. It is transported to the fatty tissue and is deposited especially in the omentum. When the pure dye is fed even in large amts., none is excreted in the urine of normal animals. It is found in the feces, soft deep red stools being obtained in from 2 to 4 hrs. Com. preps. contain more or less impurity of a toxic nature and may cause great debility, stunt the growth, produce a neuritic-like condition and be fatal in large doses. The foreign substances may be excreted by the kidney and appear in the urine as deep colored pigments.

A. P. LOTHROP.

**Action of adrenaline on the heart as studied by radioscopy.** M. LORPER, H. DUBOIS AND C. WAGNER. *Compt. rend. soc. biol.* 81, 85-6(1918).—A large no. of normal and pathol. subjects was examd. by this method before and after injection of 1 mg. epinephrine. Cardiac dilatation occurred in most of the pathol. cases; little or no change (occasionally a slight reduction in vol.) was noted with normal subjects. Cardiac dilatation produced by epinephrine appears to be a passive phenomenon caused by the counter pressure resulting from the sudden peripheral vasoconstriction. Practical constancy of heart vol. after injection of epinephrine indicates normal cardiac resistance to vascular counter pressure, while dilatation is indicative of cardiac insufficiency of some kind.

H. S. PAINE.

**Toxicity of colloidal arsenic and arsenic compounds.** L. LAUNOY. *Compt. rend. soc. biol.* 81, 164-5(1918).—The comparative toxicity of the As compds. commonly employed in therapy is as follows (order of decreasing toxicity): alk. arsenites, alk. arseniates, colloidal As, arrhenal, acetyl-atoxyl, atoxyl, Na cacodylate. Intraperitoneal injection of 0.01-0.016 g. colloidal As per kg. in guinea pigs was sufficient to cause death in 3-6 days; intraperitoneal injection of 0.0083 g. As caused death in about 10 days. The coeff. of toxicity of colloidal As was 0.0083-0.016 g. per kg. The colloidal As employed was prepd. by the Auger method; 2 samples contained 0.001245 g. and 0.0028 g., resp., of As per cc. No stabilizer was used; the solns. were transparent and of brownish color and the As was rapidly oxidized on contact with air. As in the case of other As derivs., death ensued slowly after injection of limiting toxic doses and the usual symptoms of hepatic and renal degeneration characteristic of As

intoxication were observed during this period of "incubation;" a max. loss of wt. equal to  $\frac{1}{4}$  of the original wt. was observed during this period. It was impossible to make 3 successive injections in guinea pigs (even at 8-day intervals) of 0.005 g. As per kg. each without causing death. These results are distinctly different from those reported by Sorev (*C. A.* 13, 241).

H. S. PAINE.

**Slight toxicity of colloidal arsenic obtained by mechanical means; reply to Launoy.** E. SOREV. *Compt. rend. soc. biol.* 81, 563-4(1918).—S. replies to the criticism of Launoy (cf. preceding abst.). The colloidal As employed by S. was obtained by mechanical means (24 hrs. trituration of As) instead of being produced chemically as in the case of that used by L. The particles were fully as small as those of chemically or electrically produced colloidal As and showed Brownian movements similar to those of other types of colloidal As; the particles were maintained in suspension in a gummy excipient. The above difference in method of prepn. may possibly explain in part the variation in results obtained. The difference in results is also due in part to the fact that L. employed guinea pigs while S. used rabbits as exptl. animals. The lethal dose for guinea pigs of the colloidal As used by S. was 0.03 g. per kg., while the lethal dose of L.'s colloidal As was only 0.016 g. per kg. Guinea pigs are in addition more sensitive than rabbits to colloidal As; intravenous injection in rabbits of 0.05 g. of mechanically produced colloidal As per kg. was often innocuous.

H. S. PAINE.

**Action of sodium citrate on the blood.** FOLLEY. *Compt. rend.* 167, 653-4(1918).—This study was made to det. the utility of citrated blood for use in transfusion, especially in war wounds. The expts. were made with human or rabbit blood in which 10 cc. of a 10% soln. of  $\text{Na}_3\text{C}_6\text{H}_5\text{O}_7$  were added to 200 cc. of blood. Citrated blood allowed to stand several hrs. at 18 to 23° was not coagulated by the addition of a small amt. of recent clot, or of the juices of various unwashed tissues, but was coagulated by the addition of  $\text{CaCl}_2$ . Blood of man or animal which had received an injection of gelatin, horse serum, antitetanic serum, or even its own serum, coagulated much more rapidly when removed from the vessels. This blood mixed with  $\text{Na}_3\text{C}_6\text{H}_5\text{O}_7$ , after having been properly drawn by puncture of a vein, did not coagulate more rapidly than normal blood.

L. W. RIGGS.

**Dinitrobenzene poisoning.** O. STEINER. *Correspondenz-Blatt für Schweizer Aerzte* 48, 1139(1918); *J. Am. Med. Assoc.* 71, 1445.—Seven cases are described. The mucus membranes and sometimes the entire skin are colored gray. The blood appears gray and thick, but the differential count is normal except that there is an excessive destruction of red cells. Treatment consists in O inhalations, free withdrawal of blood followed by infusion of  $\text{NaHCO}_3$  with stimulants and copious drinking of milk. Clothing should be removed from the room and the patient receive a thorough bath, especially of the hands and hair, with hot water and soap.

L. W. RIGGS.

**Atropine and induced antianaphylaxis as a protection against acute arsphenamine reactions.** J. H. STOKES. Rochester, Minn. *J. Am. Med. Assoc.* 72, 241-3(1919).—A case is reported and the following conclusions are stated: The acute "nitritoid" crisis or reaction to arsphenamine is a form of anaphylactic shock, explainable on physicochem. grounds as a result of a pptn. either of the drug from its colloidal soln., or of the colloids of the blood plasma, by the drug, or by an impurity. The reaction following the injection of an acid or only partially alkalinized soln. of arsphenamine either too rapidly or in too high concn. is presumably of the same type. The nitritoid crisis can apparently be inhibited by a previous injection of atropine ( $\frac{1}{50}$  grain), which further suggests that the reaction is a form of anaphylactic shock. The induction of antianaphylaxis as described above further supports the belief that the nitritoid crisis is a form of anaphylactic shock. The induction of antianaphylaxis in

patients exhibiting persistent idiosyncrasy to arsphenamine or neo-arsphenamine has proved clinically useful, and, as a means of increasing their tolerance of the drug, deserves further trial and study.

L. W. RIGGS.

**Research on frog heart.** C. BASTERT. *Nederlandsch Tijdschrift voor Geneeskunde* 2, 1540(1918); *J. Am. Med. Assoc.* 72, 318.—B. reports that when the heart action had been arrested by toxic action from digalen or veratrine, the heart could be started to beating again by the action of HCN. The reverse also occurs, digalen or veratrine temporarily resuscitating the heart arrested by HCN. It was also observed that the heart poisoned with digalen to complete arrest, started to beat again when the pressure was raised, while with HCN arrest it started to beat again only when the pressure was lowered. HCN arrests the heart in diastole, and overcomes the arrest when it occurs in systole. It thus acts like K in Ringer's fluid.

L. W. RIGGS.

**Influence of quinine on stomach functioning.** P. BAUFLE. *Presse Medical* 8, 418(1918); *J. Am. Med. Assoc.* 72, 380.—Test meals were given the same subjects with and without 1 g. of quinine sulfate or hydrochloride in a cachet. The stomach contents were examd. in 30 min. and again 60 min. later, the stomach being rinsed out each time with 200 cc. of water. When there is a tendency to hypersecretion the sulfate should be given the preference. With hyposecretion the hydrochloride should be selected as it stimulates sluggish glands to better secretion. It should be administered from 30 to 40 min. before the meal in 100 to 150 cc. of water. In this way the quinine will have passed out of the stomach before the meal begins, leaving the secretory glands stimulated to a high degree. The sulfate modifies conditions but little, no more than the physiol. range.

L. W. RIGGS.

**Methemoglobinemia due to poisoning by a shoe dye.** RICHARD E. STIFEL. U. S. Army. *J. Am. Med. Assoc.* 72, 395-6(1919).—Eight cases of cyanosis with headache, nausea and general malaise were connected with the wearing of newly dyed shoes, and this cause was confirmed by direct expts. with the dye in question. Chem. examn. showed that the dye contained nitrobenzene, which accounted for the symptoms. If shoes are not worn until several days after dyeing the ill effects may be avoided.

L. W. RIGGS.

## I. ZOÖLOGY.

R. A. GORTNER.

**Studies on the nutrition of fish. Experiments on brook trout.** SERGIUS MOR-  
GULIS. Creighton Univ. College of Med. *J. Biol. Chem.* 37, 391-413(1919).—Trout will remain in good condition and gain in wt. when kept in museum jars containing as little as 4-5 l. of H<sub>2</sub>O provided the H<sub>2</sub>O is properly aerated and changed every 48 hrs. Whenever possible the trout were taught to take their food directly from forceps so that the washing out of sol. constituents of the food by the H<sub>2</sub>O was entirely prevented in most cases. They were fed *ad libitum* so that there were at no time any food particles to contaminate the H<sub>2</sub>O in the aquaria and affect the significance of the results. The solid excreta were removed by filtering the contents of the jars through glass wool in modified Gooch crucibles consisting of large Al tumblers, the bottoms of which were perforated with fine holes. The glass wool was chosen because it was necessary to increase the bulk of the feces without interfering with the analysis and because it was especially serviceable in helping to reduce the dried feces to an extremely fine state of subdivision and uniform distribution when ground with them. N and fat detns. were made on the feces. The N in the dissolved excreta (urine) was detd. after concn. of the H<sub>2</sub>O from the jars by a suitable and rapid procedure. On a diet of raw beef heart the % utilization of the food under normal conditions was high, 96.1% of the protein and 94.5% of the fat being utilized. Fasting has a deleterious effect on the digestive functions of the trout and especially affects the absorption of fat, the utiliza-

tion dropping to 91.7%. "Fasting trout eliminate 80-90 mg. of N per day per kg. But if the fast has been preceded by a liberal diet, the N elimination for the first few days may greatly exceed this. About  $\frac{1}{4}$  of the loss in body wt. is at the expense of protein. A comparison of diets consisting of raw and cooked beef heart showed that both are equally well utilized in the organism of the trout, but a greater gain in body wt. is secured from the former. Increase in wt. does not bear a direct relation to the absolute quantity of food consumed. This study failed to justify the use of beef liver as a dietary article for trout."

A. P. LOTHROP.

**Fumigation with chloropicrin.** WILLIAM MOORE. *J. Econ. Entomology* 11, 357-62(1918).—Chloropicrin is mol. for mol. about 283 times as toxic to insects as  $\text{CS}_2$ . Unlike  $\text{CS}_2$ , it is not explosive unless heated; its vapors are about twice as heavy as those of  $\text{CS}_2$ ; hence they will readily disseminate downward through a mass of grain or clothing. Expts. proved that  $\frac{1}{2}$  lb. chloropicrin per 1000 cu. ft. would kill the bean weevil (*Bruchus obtectus*), the Anguimoid grain moth (*Sitotroga cerealella*), the Indian meal moth (*Plodia interpunctella*), and the Mediterranean flour moth (*Ephesia kuehniella*), but would not kill the confused flour beetle (*Tribolium confusum*) when more than 1 inch below the surface of the flour. One-2 lbs. per 1000 cu. ft. are necessary for the latter insect. If the quantity of flour fills the entire space of the container, larger doses are necessary.  $\text{CS}_2$  gives satisfactory results only above  $18.3^\circ$ , while chloropicrin is effective below  $15.6^\circ$ . The germination of grain is not injured by doses of  $\frac{1}{2}$  lb. per 1000 cu. ft.; larger doses are injurious if germination is attempted before the grain has had a thorough airing. It is also necessary that the grain be dry. Chloropicrin free from  $\text{Cl}_2$  will not bleach flour, but it has a slight effect on the baking quality of the bread through its inhibitory action on the yeast. Bread made from this flour was not toxic to lab. animals. Chemically pure chloropicrin used at the rate of 2 lbs. per 1000 cu. ft. did not affect the colors or the fabric of clothing. While not at present obtainable on the market, chloropicrin can be manufactured more cheaply than  $\text{CS}_2$ . It can not be used on a large scale unless means are provided for the rapid removal of the vapors which are extremely irritating to the eyes and nasal membranes. It is suggested as a fumigant for small quantities of seeds, for the destruction of ants nests, gophers, and in light doses for the eradication of mosquitoes in yellow fever regions.

CHAS. H. RICHARDSON.

**Observations on the mode of action of contact insecticides.** WILLIAM MOORE. *J. Econ. Entomology* 11, 443-6(1918).—When methylene blue is injected into the body of an insect in the absence of O, it is reduced to the leuco compd. and the insect's body assumes a white or yellowish white color. When an injected insect is dipped in light lubricating oil, olive oil, toluene,  $\text{CCl}_4$ , xylene, nitrobenzene, nicotine,  $\text{Et}_2\text{O}$ , soap soln. or water, the tracheae are penetrated and blocked so that the white color persists till they are removed when the blue color returns. These expts. show that a contact insecticide containing oil or soap soln. may penetrate the tracheae of an insect, preventing normal oxidation and thus killing the insect. Small insects, like the plant lice (Aphididae) are easily killed, but larger species such as the tarnished plant bug (*Lygus pratensis*) are not so easily covered, and it is necessary to add a compound to the spray which will kill through its chem. action. Some insects like the clothes louse (*Pediculus corporis*) have the ability to close the tracheae so quickly that soap solns., lubricating oils, xylene and ether can enter only with difficulty. The hog louse (*Haematopinus suis*) and the dog louse (*H. piliferus*) also possess this power, but in a lesser degree than the clothes louse. A number of other species of insects examd. did not possess this power of resisting the entrance of solns. into the respiratory system. This subject has an important bearing on the type of dips most effective against certain insects.

CHAS. H. RICHARDSON.

**Light reactions and metabolism in may-fly nymphs.** W. C. ALLER AND E. R. STEIN, JR. *J. Expt. Zoology* 26, 423-58(1918).—The nymph of *Epeorus* responds positively to light under normal conditions. A reversal in the reaction to light was induced by treatment with EtOH, CaCl<sub>2</sub>, lowered temp., and other reagents. Nymphs which showed a reversal had a lower rate of metabolism, as measured by resistance to KCN solns., than normal, untreated nymphs. Nymphs of *Leptophlebia* normally show a negative reaction to light. Their reaction was reversed by treatment with EtOH, HCl, H<sub>2</sub>SO<sub>4</sub>, KOH, NaOH, KCN, KCl, NaCl, and CaCl<sub>2</sub> with accompanying stimulation or depression as indicated by the resistance to KCN solns. A negatively responding nymph belonging to the Heptageninae was treated with HCl, KCN, EtOH, and strychnine. With HCl and KCN reversal was the rule, but with EtOH and strychnine no reversal occurred. Individuals which were reversed showed an increased CO<sub>2</sub> production as measured by Tashiro's biometer. "These expts. conclusively demonstrate that the phototactic reaction of these nymphs is correlated with the metabolic condition and indicate, but do not prove, that certain changes in metabolism cause reversal in reaction to light. All nymphs that reversed their light reactions were either stimulated or depressed, but stimulation or depression did not necessarily involve phototactic reversal."

CHAS. H. RICHARDSON.

**Studies on the physiological significance of certain precipitates from the egg of *Arbacia* and *Asterias*.** ALVALYN E. WOODWARD. *J. Expt. Zoology* 26, 459-500 (1918).—The eggs of these animals secrete a substance into the sea water which activates, aggregates, reversibly agglutinates and paralyzes the sperm of the same species. Its presence is necessary for the fertilization of the egg. Its value as a parthenogenetic agent is destroyed by boiling, which, however, does not destroy its agglutinating properties. It is apparently colloidal, contains C and N, but gives no positive tests for protein. A faint yellow color was obtained with the xanthoproteic test. With (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, a sperm agglutinin is pptd. BaCl<sub>2</sub> and acetone pptd. a parthenogenetic agent. An enzyme called provisionally lipolypsin was found in the secretion. Serum from *Asterias* and *Arbacia* inhibited autoparthenogenesis and sperm fertilization. Similar results were obtained with "Purple X" and "Salmon X," substances extracted from the testicular or ovarian tissues of *Arbacia* and *Asterias* by boiling. An anti-fertilizin obtained from eggs which have been freed from the activating secretion, and an unsaturated fatty acid which can be extracted from the eggs with ether also inhibited autoparthenogenesis and sperm fertilization. Parthenogenetic agents are placed by the author in three groups: (1) The fat solvents, including lipolypsin, Et<sub>2</sub>O, CHCl<sub>3</sub>, BuOH, etc.; (2) the halogen compds., iodine and various salts; (3) physical methods which may change the physical or quantitative relations of substances within the egg. These agents produce development in uninseminated eggs, as well as eggs which have been made resistant to fertilization. It is probable that enzymes in the resting egg tend to produce development. Their action may be inhibited by unsaturated fatty acids. The egg remains in the resting stage so long as the activity of these enzymes is inhibited by the fatty acid, but when mature and in a suitable medium, the egg produces a lipolypsin which binds the acid and development proceeds.

CHAS. H. RICHARDSON.

**Reversion in the sense of orientation to light in the colonial forms, *Volvox globator* and *Pandorina morum*.** S. O. MAST. *J. Expt. Zoology* 27, 367-90(1917).—These organisms give practically the same reactions to light; they may be either positive or negative. Colonies which have become adapted to the dark usually react positively in weak and negatively in strong illumination. Colonies adapted to light are sometimes positive in strong and negative in weak illumination. Continuous illumination causes dark-adapted colonies to become at first neutral, then positive, passing through

a maximum, then neutral again, then negative, passing through a maximum, neutral a third time and finally positive. Reversion is dependent upon the time of exposure as well as the intensity of illumination. More energy in meter-candles hrs. is required to induce reversion in high than in low illumination. Reversion is not primarily dependent upon photosynthesis because red and yellow light, in which photosynthesis is relatively strong, have little effect on reversion. Green and blue light, while relatively weak in photosynthetic power, have the greatest stimulating efficiency and are most potent in producing reversion. Increase in temp. causes negative specimens to become positive; decrease in temp. causes the reverse, but the response to temp. is subject to considerable variation. Alkalies, EtOH and Et<sub>2</sub>O have practically no effect on reversion. Acids and CHCl<sub>3</sub> cause negative colonies to become strongly positive, but reversion is not specifically dependent on the concn. of the chemicals. The effect of acids is probably due to the accompanying reduction in alkalinity of the culture soln. The sense of orientation to light is dependent upon the physiological state of the colonies and the constitution of the culture medium. Young colonies are more likely to be negative than old. Reversion is probably associated with changes in permeability, positive orientation being associated with an increase and negative orientation with a decrease in permeability.

CHAS. H. RICHARDSON.

Effects of chemicals on reversion in orientation to light in the colonial form, *Spondylomorom quaternarium*. S. O. MAST. *J. Expt. Zoölogy* 26, 303-30(1918).—This colonial animal responds positively or negatively to light, depending upon the conditions. CHCl<sub>3</sub>, Et<sub>2</sub>O, chloral hydrate, H<sub>2</sub>CO<sub>3</sub>, HCl, HNO<sub>3</sub>, H<sub>2</sub>SO<sub>4</sub>, MeOH, H<sub>2</sub>BO<sub>3</sub>, H<sub>2</sub>CrO<sub>4</sub>, tannic acid, tartaric acid and oxalic acid made negative specimens become strongly positive, but were without effect on positive specimens except perhaps to make them more strongly positive. EtOH, NH<sub>4</sub>Cl and pure H<sub>2</sub>O are without appreciable effect on positive colonies, but probably cause negative colonies to become slightly positive. HCHO, sucrose, O<sub>2</sub>, H<sub>2</sub>O<sub>2</sub>, MgSO<sub>4</sub>, CaCl<sub>2</sub>, KNO<sub>3</sub>, NaOH, KOH and NH<sub>4</sub>OH are without effect on the sense of orientation. Increase in concn. of the culture solution causes positive colonies to become strongly negative; decrease in concn. causes negative colonies to become strongly positive. Increase in temp. and decrease in illumination cause negative colonies to become positive; decrease in temp. and increase in illumination cause positive colonies to become neg. But the sense of orientation is not specifically related to the concn. of chemicals in the environment. This species may probably be either positive or negative in any soln. in which it will orient at all. Acids probably affect the sense of orientation by reducing the concn. of OH<sup>-</sup> in the culture solns. It is thus apparent that the same change in orientation may be effected by a number of different factors. Change in orientation is probably due to some specific change in the physiol. process in the organism. Change in orientation depends upon the time rate in the change of concn. or intensity of the effective factors, but it has not been shown that this depends upon the time rate of change in the physiol. processes involved in the reaction.

CHAS. H. RICHARDSON.

Relative effectiveness of food, oxygen and other substances in causing or preventing male-production in *Hydatina*. A. FRANKLIN SHULL. *J. Expt. Zoölogy* 26, 521-44(1918).—Expts. made with *Hydatina* in H<sub>2</sub>O satd. with air mixtures containing 40% and 60% O<sub>2</sub> showed that O<sub>2</sub> is a male-producing agent. The lower concn. was probably a little more effective than the higher. Cultures in which *Euglena* was used as food contained about 62% more O<sub>2</sub> than cultures containing manure scum. The *Euglena*-containing cultures showed an increase in male-production over controls, partly due to the O<sub>2</sub> liberated by *Euglena* and partly, presumably, to the food value of *Euglena* itself. *Euglena* with crude creatine soln. was more effective in male-production than manure scum and oxygenated creatine soln., manure scum and untreated

creatine soln. or manure scum and untreated spring H<sub>2</sub>O. Manure soln. had a repressing effect upon male production which was a little more than offset by the presence of *Euglena* in the cultures. (Cf. C. A. 12, 2099.) CHAS. H. RICHARDSON.

**Demonstration of epithelial movement by the use of vital staining, with observations on phagocytosis in the corneal epithelium.** SHINICHI MATSUMOTO. *J. Expt. Zoology* 27, 37-46(1918).—The epithelium of the cornea of the frog when vitally stained with neutral red and Nile blue exhibited characteristic granules in the cytoplasm. With proper staining, these granules existed throughout the entire period of cell activity, without affecting the cell. The corneal epithelium showed phagocytic activities, taking up both melanin and carmin granules, the position of these granules within the cell being demonstrated by vital staining. The melanin and carmin granules resembled in distribution and arrangement those of neutral red and Nile blue.

CHAS. H. RICHARDSON.

**Anabiosis of the earthworm.** PETER SCHMIDT. *J. Expt. Zoology* 27, 57-72(1918).—Desiccated earthworms lose their mobility completely, diminish in length and vol. to  $\frac{1}{4}$ , or  $\frac{1}{5}$  of the original and appear dead. They can be revived from this state after 39 hrs. at normal summer temp. and after 48 hrs. and perhaps longer at low temp. "Earthworms can revive and regain the normal state of life after a loss of 61.6% of the wt. of the body, or nearly 73% of the wt. of the water contained in the body." The similar results of desiccation in Tardigrada, Rotatoria and Nematodes are considered.

CHAS. H. RICHARDSON.

**The reaction of selachii to injections of various non-toxic solutions and suspensions (including vital dyes), and to excretory poisons.** E. R. HOSKINS AND M. M. HOSKINS. *J. Expt. Zool.* 27, 101-55(1918).—The dog fish, *Musculus canis*, was used in these expts. The digitiform gland excreted 1 cc. per day of a clear, alkaline fluid containing urea. Injected solns., but not suspensions, were recovered from this fluid. Injected excretory poisons, K<sub>2</sub>CrO<sub>4</sub>, tartaric acid and uranium nitrate injured the digitiform gland. Injected solns. were excreted from the kidney of the dogfish as rapidly as from the mammalian kidney. Injected particulate matter was not excreted and insol. vital dyes did not stain the kidney tubules. The excretory toxins were withstood for long periods, eventually producing nephritis. The liver excreted both injected solns. and suspensions, the quantity excreted in a given time being several times greater than that excreted by the kidneys. The liver was stained by insol. dye particles. It was the only organ found which excreted suspended particles. The excretory toxins caused very little injury to the liver which probably excreted them. Injected insol. dyes stained the spleen deeply, the injected particles producing leucocytosis. The excretory toxins caused congestion of the spleen and injured its endothelium. The spiral valve, previously supposed to have an excretory function, would not excrete all the sol. substances injected and insol. dyes were not taken up by its epithelium. The excretory poisons passed through the epithelium of the spiral valve and destroyed it. The stomach did not appear to possess an excretory function. The gill endothelium stored injected trypan blue and coarsely powdered carmine in greater quantity than any cells of the body. The excretory toxins produced proliferation and abnormal amitosis of the endothelial cells of the gills. No evidence that the gills have an excretory function was deduced. The muscles, skin and peritoneum were negative in reaction to non-toxic solns., vital dyes and the toxins used. Sucrose was inverted by the blood of the dogfish, but other non-toxic solns. were reacted to negatively by the blood vascular system. Trypan blue and carmine were occasionally found in the leucocytes and endothelial cells of many organs and tissues. They were of much more frequent occurrence in the endothelium of the bronchial and splenic sinuses and the hepatic sinusoids. The lymphatics were not noticeably stained with vital dyes. The excretory

poisons slightly injured the fixed endothelial phagocytes, especially of the spleen and gills, and caused congestion in all the organs with varying severity. Intramuscular injection of the excretory toxins caused a slow degeneration of the erythrocytes, intravenous injection a sudden destruction of them.

CHAS. H. RICHARDSON.

The effect of adrenine on the pigment migration in the melanophores of the skin and in the pigment cells of the retina of the frog. ANDREW JOHNSON. BIGNEY. *J. Expt. Zoölogy* 27, 391-6(1919).—The frogs *Rana pipiens* and *R. clamitans* were used in these expts. The reactions towards adrenine were the same in both species. Normally, the pigment in the melanophores expands in the light and contracts in the dark. A soln. of adrenine of the proper concn., when injected into the dorsal lymph sac of the frog, causes a contraction of this pigment if it has been previously expanded by light, but if the pigment is already contracted, the adrenine does not alter its position. Concns. of 1:50,000 caused a slight contraction of pigment in expanded melanophores while concns. of 1:500,000 were not effective. Melanophores contracted with adrenine remained in this condition for about 2 hrs.; in 4-5 hrs. they became fully expanded again. The migration of retinal pigment is outward from the cell under the influence of light and into the cell in darkness. Adrenine caused the pigment to expand in the retracted retinal cells, a movement just the reverse from that noted in the melanophores. The effect could be observed with concns. of adrenine of 1:5,000,000. The duration of the expansion of retinal pigment caused by adrenine was about 4 hrs. The optic nerves are not concerned in this action. It is probable that the effect is produced by the adrenine carried by the blood.

CHAS. H. RICHARDSON.

Studies on the relation of iodine to the thyroid. I. The effect of feeding iodine to normal and thyroidectomized tadpoles. W. W. SWINGLE. *J. Expt. Zoölogy* 27, 397-415(1919).—Iodine,  $\text{CHI}_3$  and  $\text{KI}$ , when fed with wheat flour, rapidly stimulated metamorphosis in larvae of *Rana pipiens* and *Bufo lentiginosus*. Iodine also brought about metamorphosis in thyroidless larvae of *Bufo lentiginosus* in an abnormally short time. Normal and thyroidless larvae were quickly killed by very weak solns. of  $\text{I}_2$ ; the addition of flour appeared to restrain this toxic action. The expts. indicate that iodine functions within the organism as a hormone without the intermediation of the thyroid gland, and that the function of this gland is chiefly one of iodine storage. It is suggested that the function of the thyroid under pathological conditions may be entirely different. II. Comparison of the thyroid glands of iodine-fed and normal frog larvae. *Ibid* 417-25.—Thyroid glands of iodine-fed frog larvae are larger than those of controls held at the same body length by underfeeding and the gland follicles of the iodine-fed larvae contain a much greater colloidal mass. Solns. of  $\text{I}_2$  will bring about metamorphosis in frog larvae in a short time. The same effect can also be obtained with  $\text{CHI}_3$  and  $\text{KI}$ , but neither is as active as  $\text{I}_2$ .  $\text{KIO}_3$  apparently has no effect, although eaten readily. It is suggested that amphibian metamorphosis results from the interaction of environmental agencies, such as iodine and its compds., but that the growth processes are controlled by hereditary factors.

CHAS. H. RICHARDSON.

Acclimatization as a factor affecting the upper thermal death points of organisms. M. H. JACOBS. *J. Expt. Zoölogy* 27, 427-42(1919).—The temp. coeff. for starfish larvae, 48 hrs. old, at temps. from 32 to 40° is approx. 2, as derived by the author's formula. For *Paramécium caudatum*, however, this value is more variable, often ranging from 3 above 40° to less than 2 below 40°. A method is given for the calcn. of the theoretical death point when the temp. is raised uniformly at a given rate. A comparison of this theoretical value with the observed death point will indicate whether acclimatization has occurred. Starfish larvae showed practically no acclimatization while *Paramécium* showed considerable. This amount of "surplus resistance" was detd. quant. for *Paramécium*. Generally, the slower rates of temp. increase were more favorable for

*Paramecium*, but more unfavorable for starfish larvae than the more rapid ones. It is suggested that further data on the upper thermal death points include exact statements as to the methods by which the temps. have been obtained as well as the times of exposure to the temps.

CHAS. H. RICHARDSON.

Temperature coefficient of the action of  $\beta$ -rays upon the eggs of *Nereis*. ALFRED C. REDFIELD AND ELIZABETH M. BRIGHT. *J. Gen. Physiology* 1, 255-9(1919).—The temp. coeff. of the action of  $\beta$ -rays from Ra upon the eggs of *Nereis* lies between 1.1 and 1.2 for a change of  $10^\circ$ ;  $\alpha$ -radiation was eliminated and the effect of  $\gamma$ -radiation was found to be negligible as compared with the action of the  $\beta$ -rays. This coeff. is of a magnitude characteristic of photochemical reactions.

C. H. R.

The experimental production of edema in larval and adult *Anura*. CHARLES F. W. MCCLURE. *J. Gen. Physiology* 1, 261-7(1919).—Edema is a common abnormality in frog larvae which can be produced experimentally by placing the 2- or 4-celled stage ova in solns. of KCN, acetone, butyric acid, EtOH, or by exposing them to the influence of radium. These edematous larvae are without exception characterized by the hypertrophy of certain tubules in the pronephros. A similar edematous condition was produced in toads (*Bufo lentiginosus*) which after the ureters had been ligated were kept in water. The progress of the edema appeared to be related to the extent and character of the abrasion produced in the tissues at the point of ligation and the state of congestion of the tissues resulting from ligation. It is believed the edematous condition in frog larvae is due to the failure of the tubules of the pronephros to function normally with the consequent accumulation of fluid in the body cavity and tissues. These observations do not bear out Fischer's view (Aedema and Nephritis, New York, 2nd Ed. 1915) that the cause of edema in the *Anura*, is due to an overproduction or accumulation of acids within the body which causes the tissues to take up water.

CHAS. H. RICHARDSON.

Studies on bioluminescence. IX. Chemical nature of Cypridina luciferin and Cypridina luciferase. E. NEWTON HARVEY. *J. Gen. Physiology* 1, 269-93(1919); cf. C. A. 13, 241.—Luciferase is a protein or at least it is so closely associated with proteins that it cannot be removed without destruction; it is probably an albumin. It has sufficient properties in common with enzymes to be classed as an enzyme. Whole dried Cypridinae contain Fe, Cu and Mn, but it is not certain that these are concerned in the action of luciferase. Luciferin is probably a new, natural proteose, sol. in alc. and not digested by trypsin.

CHAS. H. RICHARDSON.

Nature of the retarding influence of the thymus upon amphibian metamorphosis. EDUARD UHLENHUTH. *J. Gen. Physiology* 1, 305-13(1919).—Thymus feeding sometimes retards and in rare cases inhibits metamorphosis completely in salamander larvae. The addition of normal food (earthworms) to the thymus diet prevented the inhibitory action of the thymus. A small quantity of iodothyryn added to the thymus diet led rapidly to precocious metamorphosis. The inhibitory effect of the thymus is not caused by a specific inhibiting substance in the thymus, but the absence from this gland of a substance required to develop the thyroid to the secretory state. The expts. were performed on the salamanders, *Ambystoma maculatum*, *A. opacum* and *A. tigrinum*.

CHAS. H. RICHARDSON.

Rate of recovery from the action of fluorite rays. W. T. BOVIE AND D. M. HUGHES. *J. Gen. Physiology* 1, 323-9(1919).—*Paramecium caudatum* was exposed to the influence of fluorite radiation, the intensity of the radiation being such that an exposure of 8 secs. produced cytolysis in 57% of the exposed organisms. The organisms were given two exposures of 4 secs. each, sepd. by an interval of varying duration. An increase in the length of the interval between the two exposures resulted in a decrease

in the percent. of cytolysed paramacia. The curve resulting from plotting the percentages of cytolysis as ordinates and the time intervals as abscissas corresponded with the curve derived from the monomolecular reaction formula  $X = X_0 e^{-kt}$ . The percentage of cytolysis increased with the length of exposure; the curve was practically a straight line. Cytolysis occurs when a certain amt. of a toxic photo-product is formed; recovery depends upon the removal of this toxic substance. A chemical process and diffusion are suggested as possible methods for its removal. C. H. R.

**Sensitization to heat due to exposure to light of short wave lengths.** W. T. BOVIE AND ALICE KLEIN. *J. Gen. Physiology* 1, 331-6(1919).—When *Paramecium caudatum* was exposed to fluorite rays for 4 seconds at 17-18° death did not result, but subsequent heating for 60 seconds at 16-17° resulted in a 10% mortality. Heat alone at the same temp. and duration was not fatal. Heating at 24-26° for 60 seconds, then exposing to the radiation for 4 secs. gave an 8% mortality, while subjection to the radiation followed by a temp. of 24-26° for 60 min. caused a 66% mortality. The % of recovery increased with the increase in the interval between radiation and subjection to temp.; with a period of 1/2 hr., the percent. of death was 20, while with a five hr. period it was 0. The death of *Paramecium* following fluorite radiation is a destruction by heat, the organism having been sensitized to heat in such a way that it can no longer endure normal optimum temps. No theory of the action of rays can be complete which does not take heat sensitization into account. CHAS. H. RICHARDSON.

## 12. FOODS.

W. D. BIGELOW AND F. F. FITZGERALD.

**Estimation of lactose in admixture with sucrose and invert sugar.** J. GROSSFELD. *Z. Nahr.-Genussm.* 35, 249-56 (1918); *Physiol. Abstracts* 4, 404.—Formulas are given for the calcn. of lactose from the optical activity of the mixt. E. J. C.

**Utilization of grape-seed in California.** PAUL SERRE. *Compt. rend. acad. agr. France* 5, 150-1(1919).—In California 550 tons of sirup, 340-350 tons of oil, 330-440 tons of tanning ext. and 1600-2000 tons of cattle feed are annually recovered from grape seed. This industry is dependent on wine-making. The grape sirup is obtained by simple maceration and subsequent concn. The oil, used by painters and soap mfrs. as well as to adulterate olive oil, is extd. by means of hydraulic presses with the application of heat. A small proportion is extd. by means of benzine or CS<sub>2</sub>. The oil cake is treated with H<sub>2</sub>O in special kettles in order to make a tanning ext. which is concd. to a pasty state and then dried in the air. The residue forms a cattle feed. ALBERT R. MERZ.

**Wartime vegetable oils (KLIMONT) 27.** Publications on military sanitation (STRUNK, MATTHES, et al.) 7.

SPRIGGS, E. I.: Food and How to Save it. London: Government. 2nd Ed. 52 pp. For review see *Expt. Sta. Record* 39, 367(1918).

WILEY, HARVEY W.: *Beverages and their Adulteration. The Origin, Composition, Manufacture, Natural, Artificial, Fermented, Distilled, Alkaloidal and Fruit Juices.* Philadelphia: P. Blakiston's Son & Co. 421 pp. \$3.50.

**Assimilable organic phosphorus compound from vegetable foodstuffs.** M. GIRARD. U. S. 1,290,971, Jan. 14. The pat. relates to the obtainment in a purified condition of the org. compd. contained in most vegetable foodstuffs such as seeds or oil-cake (obtained by Posternak) and usually considered to be a salt or mixt. of salts of an "anhydro-oxyethylene-diphosphoric acid" having the assumed formula  $C_2H_2P_2O_6$ . 450 kg. of a 30% paste of the tetrabasic insol. Ca salt of the org. P compd. are dissolved in 60 kg. of 30% HCl to effect conversion into the sol. dibasic Ca salt. The brown and somewhat malodorous product is mixed with 0.5 kg. animal charcoal, well stirred for about a half hr., filtered and the Ca, which is not combined with the P compd., is pptd. by addition of oxalic acid. Ca oxalate formed is filtered out and the dibasic salt of the organic P compd. is pptd. from the filtrate by the addition of alc., washed and dried. It is obtained as a dazzling white, odorless and tasteless powder. The animal charcoal may be replaced by 2.5 kg. of siliceous marl. The purified product contains 22.4% P.

**Food for animals.** A. E. BROMLEY. Brit. 121,568, May 27, 1918. A food for animals having tonic properties comprizes cattle meal, preferably consisting of maize, meal, salt, Epsom salts, saltpeter, ginger, black antimony, flowers of S, fenugreek,  $NaHCO_3$ , liquorice, aniseed, linseed meal, charcoal powder, Peruvian bark, and gentian root. The mixt. may be used alone or mixed with other food or drink. The specification gives the proportions in which the ingredients are to be mixed.

**Food for animals.** G. W. LENSVELT. Brit. 121,586, Sept. 13, 1918. Cake for cattle is manufd. from yellow mustard seed by crushing it, steaming it to remove allyl mustard oil, drying it, and finally pressing it in the ordinary way to expel fatty oil and form cakes.

**Preserving grain, seeds, nuts, etc.** J. W. C. HAMILTON and E. W. QUIRK. Brit. 121,650, Jan. 10, 1918. Grain, seeds, nuts, etc., are sterilized by treatment with the vapor of HCHO or paraformaldehyde. The seeds, etc., to be treated are passed through a mixer by screw conveyors in the opposite direction to the course of the vapor, which enters by a pipe at a pressure of about 2 lb. per sq. in. and escapes by a relief valve. The seeds, etc., enter the app. by a hopper provided with a grid which sifts out stones, etc., and escape through an air-lock. The seeds in the hopper prevent the escape of vapor.

**Sterilizing milk or other liquids easily dissociated by heat.** O. LOBECK. Holl. 2,657, Oct. 15, 1918. Liquids such as serum, blood, hematogen, and the like, are heated quickly, through a series of intermediate temps., to not more than  $100^\circ$ , which is the sterilizing temp., and maintained at that temp. for several seconds.

**Flavoring fats.** J. DE BRUYN. Brit. 121,711, Aug. 12, 1918. A substance for imparting a special, especially a butter-like flavor, to edible fats or oils is made from oil-bearing seeds or fruits after removal of the oil. The defatted seeds are ground to a fine powder which is made into a smooth mixt. with  $H_2O$  contg. a small proportion of alkali. The mixt. is then treated with a proteoclastic enzyme, such as pepsin, and a culture of lactic bacteria, such as are used in butter-starters. The mixt. may, before treatment with enzyme and bacteria, be dried to a powder, which is mixed with  $H_2O$  and treated like the original mixt. when required for use. The skin and germ may be removed from the seeds before the sepn. of the oil. Cf. C. A. 13, 149.

## 14. WATER, SEWAGE AND SANITATION.

EDWARD BARTOW AND W. F. MONFORT.

**United States water laboratories in France.** EDWARD BARTOW. *Eng. News-Record* 82, 331(1919).—The duties of the lab. staffs include sanitary surveys of occupied areas; bacterial and chem. control of filter plants operated by the U. S. A.; industrial analyses of waters used in locomotives, laundries and airplane motors; and a comprehensive study of water supplied to troops in transit. FRANK BACHMANN.

**Color of water.** WILDER D. BANCROFT. Cornell Univ. *J. Franklin Inst.* 187, 249-71(1919).—A review of the literature. "The literature on the color of water is widely scattered; it appears not to have been read by anybody; and it is somewhat contradictory. It has, therefore, seemed desirable to collect the material in an accessible form as it constitutes an interesting chapter in the general subject of the colors of colloids." JOSEPH S. HEFURN.

**Tablets for the disinfection of drinking water.** B. FANTUS. *J. Am. Pharm. Assoc.* 7, 1034-8(1918).—Tablet triturates of chlorinated lime were prepared and assayed. The tablets weighed from 0.12 to 0.14 g. and contained 0.03 to 0.4 g. of available Cl. The tablets were sealed in tubes each containing 19 and the tubes kept for varying periods. At intervals a tube was broken and the tablets assayed for available Cl. In 4 mo. the loss in strength was about 40% and in 11.5 mo. 82.5%. Compressed tablets weighing about 0.105 g. were prepared from 30%  $\text{CaCl}_2\text{O}$ , using NaCl and weaker  $\text{CaCl}_2\text{O}$  as excipient. After assay, these were stored in the dark in a well stoppered bottle and from time to time some were removed for assay. The loss in available Cl was about 10% of the initial strength per mo., but the rate decreased with age. F. notes that the deterioration is in effectiveness rather than in quality since in 6 mo. the tablets would still be as useful as ever to disinfect perhaps half the quantity of infected  $\text{H}_2\text{O}$ . Tablets of  $\text{CaCl}_2\text{O}$  require about 30 minutes to disinfect water. If a little citric acid be added to the water the time is reduced to 10 min. The water also tastes better if citric acid be used. "Halazone" (*p*-sulfonedichloroaminobenzoic acid) slowly yields available Cl when in soln. The product is harmless to the higher animals. "Halazone" tablets were found to be stable after 3 mo. storage. L. E. WARREN.

**Find cause of obnoxious tastes in Milwaukee water.** H. P. BOHMANN. *Eng. News-Record* 82, 181-2(1919).—Investigation proved that coal-tar derivs. from coke and phenol plants produced taste when dild. 1 part in 500 million. Tastes were noticeable in the supply only when south and southwest winds were blowing. The source of the waste containing coal-tar derivs. was traced to manufacturing plants discharging waste into the lake. Combination of Cl, used as disinfectant for the water supply, with these derivs. imparted obnoxious tastes to the supply. FRANK BACHMANN.

**Water supply.** P. A. A. F. EIJKEN AND B. C. P. JANSSEN. Batavia. *Geneesk. Tijdschr. v. Ned.-Indië* 58, 149-56; *Chem. Weekblad* 15, 1362(1918).—Discussion and comparison of analyses of water from 18 possible sources of supply for Batavia. These are chiefly artesian wells at Batavia and springs at Buitenzorg. The supply is more than sufficient for the calcd. requirements as far ahead as 1935. JULIAN F. SMITH.

**Philippine water-supplies get strict sanitary supervision.** GEORGE W. HEISE. *Eng. News-Record* 82, 238-40(1919).—The govt. encourages wells by paying  $\frac{2}{3}$  of cost. Surface water supplies are dangerously contaminated. The death rate has been reduced 50% by use of good water. FRANK BACHMANN.

**Remarks concerning "the occurrence of hydrogen selenide in rain and snow."** P. KARRER. *Helvetica Chim. Acta* 1, 499(1918); cf. Gassmann, *C. A.* 12, 2033.—K. has repeated the expts. of G. and concludes that Se is not present in snow or rain. E. J. C.

**Design and operation of Fort Meyer, Virginia, sewage-treatment plant.** LEONARD S. DORN. *Eng. News-Record* 82, 244-6(1919).—The plant consists of a one-story septic tank, dosing chamber and sprinkling filter. It was designed for a population of 2,000 and cost \$8,000. Av. flow was approx. 47 gal. per capita. Tests show the raw sewage to contain: grease 115, total solids 1169, suspended matter 571 parts per mil. An av. detention period of 4½ hrs. removed 72% of suspended org. matter. The filter operated at rate of 30,000 population per acre. Stability was always obtained. Sludge is disposed of in trenches where it is allowed to dry.

FRANK BACHMANN.

**War's influence on the garbage pail.** F. C. BAMMAN. *Eng. News-Record* 82, 373-8(1919).—The amt. of garbage collected during 1918 averaged about 10% less than that collected in 1917. The grease content of 1918 averaged 18% less than in 1917 and 25% less than in 1916. Grease recovered was 28% less than in 1917. Changes to feeding during the year totaled 40, some being cities over 10,000 population; changes to reduction totaled 3. The amt. of garbage still wasted is sufficient to produce more than 30 million lbs. of grease, 60,000 tons of fertilizer tankage and 40 mil. lbs. pork.

FRANK BACHMANN.

**Shipping board protects health of shipyard men.** PHILIP S. DOANE. *Eng. News-Record* 82, 422(1919).—The creation of a department of health and sanitation by the U. S. Shipping Board gave protection to men in yards through control of food and, water supply, sewage and garbage disposal and abatement of flies and mosquitoes.

FRANK BACHMANN.

**American engineer at Burma camp fights epidemics.** HARRY N. JENKS. *Eng. News-Record* 82, 339-40(1919).—Guards were placed around the camp to keep out stragglers. Uncooked foods in infected areas were destroyed. A detention camp on the railroad line proved effective. Influenza, plague and cholera were the diseases combated during a 6 mo. period.

FRANK BACHMANN.

**Sanitary engineers get direct results in East Indian mining camp.** HARRY N. JENKS. *Eng. News-Record* 82, 172-5(1919).—Results obtained at Burma Mines, Namtu, Burma. Intensive clearing and drainage in mosquito control was done utilizing cheap labor instead of oiling. Water supply was derived from springs in swamps. Human excreta are disposed of by latrine system. In Namtu proper the wet pail system is used with final deposit in latrines. Bath house water and kitchen sink waste are discharged onto the ground and flows down the hillside through ditches. F. B.

**Vehicular tunnels under the Hudson River.** MARTIN SCHREIBER. *J. Franklin Inst.* 187, 273-88(1919).—The ventilation of the proposed vehicular tunnel under the Hudson River between Jersey City and Manhattan Island is described. A résumé is given of ventilation tests (including air analyses for unsatd. hydrocarbons, CO, CO, O, and N) conducted in an air-tight exptl. chamber, which had exactly the same cross section as the proposed tunnel, was provided with a similar ventilating system, and contained automobiles with engines in operation.

Preventing and removing boiler incrustation. J. URRUTY. *Brit.* 121,590, Nov. 8, 1918. A compn. for removing incrustation from condensers and boilers consists of  $\text{HCl}$ ,  $\text{CuSO}_4$ ,  $\text{NaHCO}_3$ ,  $\text{KCN}$ , and  $\text{H}_2\text{O}$ . The following mixt. is used to prevent incrustation: oak bark,  $\text{NaHCO}_3$ ,  $\text{Na}_2\text{AlO}_2$ , and  $\text{H}_2\text{O}$ .

## 15. SOILS, FERTILIZERS AND AGRICULTURAL POISONS.

J. J. SKINNER.

Soil acidity as affected by moisture conditions of the soil. S. D. CONNER. *Ind. Agr. Expt. Sta. J. Agr. Research* 15, 321-31(1918); cf. *C. A.* 11, 3363.—Four different types of acid soils were kept at moisture condition, one-fourth satd., one-half satd., and fully satd., for a period of 1 yr. The change in acidity was detd. by three methods: the Jones  $\text{Ca}(\text{OAc})$ , method, the Hopkins  $\text{KNO}_3$ , method, and the ethyl acetate method. The results from the 3 methods agreed well and showed that all the types of soils, when kept one-half satd., increased in acidity and the same was generally true for the one-fourth satd. samples, although the acidity was lower. Of the fully satd. soils those high in org. matter developed considerable acidity while those low in org. matter showed no gain and often a loss in acidity. When the samples were air-dried before the detn., those which had been kept fully satd. showed a loss in acidity. The  $\text{KNO}_3$ , exts. of the fully satd. soils contained much more Fe and Al than those having a lower moisture content, the Fe being in the ferrous state. R. N. HARGER.

Limestone action on acid soils. ROBERT STEWART AND F. A. WYATT. *Urbana. Ill. Agr. Expt. Sta., Bull.* 212, 267-96(1919).—The annual loss of limestone from soils depends upon a number of factors among which are the kind, the form and the amt. added. It is shown that the loss of limestone is not as large as is generally assumed. As an av. of all detns., the annual loss from the surface 20 inches was 760 lbs. per acre from one field and 542 lbs. per acre from another. It would thus appear that for the common prairie land of southern Illinois an application of 1 ton per acre of limestone once in 3 or 4 years is sufficient to keep the soil alk., or sweet, after the initial acidity has been destroyed by heavier applications. Dolomitic limestone can be used successfully on acid soils. It is slightly more effective than high-Ca limestone in neutralizing the soil acidity, is more durable, and has no injurious effects on the soil crops. No evidence was secured as a result of 4 years' work that finely ground limestone is more effective in correcting soil acidity than is the total product from a  $1/4$ -inch screen

which contains both the finer material for immediate use and the coarser material for greater durability. Limestone applied to the surface slowly penetrates into the subsurface, but does not seem to have any effect upon the acidity of the subsoil. The amt. of native limestone found in the subsoil is a variable quantity. In some cases there is none present even at a depth of 40 inches, whereas in other cases it extends upward even slightly into the subsurface. The results obtained give evidence that chem. analysis may be depended upon to measure the acidity of the soil, the reduction of acidity due to the action of limestone applied, and also to find the limestone still remaining in the soil, whether from the applications made or from a supply native to the soil.

W. H. ROSS.

**The effect of heat on the lime requirements of soils.** H. A. NOYES. *Purdue Univ. Agr. Expt. Sta. J. Am. Soc. Agron.* 11, 70-1(1919).—In the detn. of the acidity of the soil by the Veitch method the sample is first treated with dil. lime water, and the mixt. then evapd. to dryness on the steam bath. It is now shown from an examn. of samples of soil collected at different depths and in different places that reactions take place in the soil at the temp. of the steam bath that do not take place when the soil and water mixt. is not heated. The Veitch detn. gives the reaction between soil, water and  $\text{Ca}(\text{OH})_2$  at steam bath temp., but it is held that this does not represent the lime requirement of the soil at ordinary temps.

W. H. ROSS.

**A chlorine index as a comparative measure of the richness of earths in humus.** L. LAPICQUE AND E. BARBÉ. *Compt. rend.* 168, 118-21(1919).—The oxidation of humus by  $\text{NaOCl}$  was used to det. the relative amts. of humus in soils. Ten cc. of earth are shaken in a flask with 50 cc. of a  $\text{NaClO}$  soln. (Eau de Javel) at intervals during  $\frac{1}{2}$  hr. Two cc. of the supernatant liquid are dild. with 50 cc.  $\text{H}_2\text{O}$  and titrated with thiosulfate after addition of 5 cc. of a 20%  $\text{KI}$  soln. and 2 cc.  $\text{HCl}$  (using starch as indicator). The difference between the result obtained and that obtained with 2 cc. of fresh hypochlorite soln. multiplied by 2.5 gives the vol. of active  $\text{Cl}$  withdrawn by 1 cc. of earth ( $\text{Cl}$  index). A table is given showing the indices obtained with soils from various sources.

ALBERT R. MERZ.

**Nitrogen relations of certain crop plants when grown alone and in association.** R. C. WRIGHT. *Bur. Plant Ind. J. Am. Soc. Agron.* 11, 49-66(1919).—A study was made of the behavior of representative field crops when grown alone and in combination with other crops. In the first season's expts. the non-legumes barley, rye, oats, and kafir were each grown in the same soil with one of the legumes, vetch, field peas and red clover; corn was also grown with oats and millet. The soil used in the expts. was contained in large galvanized iron buckets holding 45 kg. of moist soil. When 2 species of plants were grown in association, half the number of plants of each were used as when grown alone. Crops were grown to maturity and harvested close to the ground. When account was taken of the  $\text{N}$  occurring in the soil and in the plant after harvesting, it was found that there was a distinct loss of  $\text{N}$  when barley was grown with peas, rye with peas or clover, and corn with millet. There was a gain in  $\text{N}$  when barley was grown with vetch or clover, oats with peas or clover, and kafir with vetch. In general, when barley and vetch or clover, oats and vetch or peas, and kafir and vetch were grown together, although more dry matter and  $\text{N}$  were produced, not so much  $\text{N}$  was removed from the soil as when these crops were grown alone. Oats and kafir gained in percentage of  $\text{N}$  when grown with vetch, peas or clover, and corn lost with both oats and millet. All other crops gained in percentage when grown with some crops, and lost with others. Similar expts. were repeated the following season, using 3 types of soil from the states of California, Kansas and Virginia. Oats, barley and kafir were used as the non-legumes, and soy beans and purple vetch as the legumes. For each of the combinations there was found to be a gain of  $\text{N}$  during the growth of the crop in one

or more of the soils, and a loss in the others. Oats and kafir when grown with vetch, and soy beans when grown with oats or barley, gained in percentage of N in all soils; while barley with soy beans, and vetch with barley or kafir lost in all soils. Other combinations gained in some soils and lost in the others. W. H. ROSS.

**Influence of higher plants upon bacterial activities in soils.** T. L. LYONS. *J. Am. Soc. Agron.* 10, 313-22(1918).—An address delivered before the 11th ann. meeting of the Am. Soc. of Agron., Jan. 6, 1919. J. J. SKINNER.

**Farm practice in growing sugar beets in Michigan and Ohio.** R. S. WASHBURN, L. A. MOORHOUSE, T. H. SUMMERS AND C. O. TOWNSEND. U. S. Dept. Agr., *Bull.* 748, 45(1919).—The general subject of sugar beet growing, soil requirement, cultivation, and development of the industry is considered. J. J. SKINNER.

**Fertilizer experiments on sugar cane.** W. E. CROSS. *Rev. ind. agr. Tucuman* 9, 72-85(1919).—A new series of fertilizer expts. on Java canes, in which  $K_2SO_4$ , Thomas slag or phosphate and  $(NH_4)_2SO_4$  were used, each one by itself, on limed and unlimed land, showed that neither K nor P increased the yield of cane or sugar. The phosphate on unlimed land delayed maturity of the cane.  $(NH_4)_2SO_4$  gave a definite increase in all cases, which was, however, unprofitable in three cases out of four. F. W. ZERBAN.

**The value of manure on Indiana soils.** A. T. WIANCKO AND S. C. JONES. *Purdue Agr. Exp. Sta., Bull.* 222, 20(1918).—A rept. is made of field expts. with manure on several soil types in different parts of the state. In a rotation of corn, wheat and clover, manure added in amts. of 10 tons per acre in the rotation produced, on the limed Volusia silt loam, an increase of 20.2 bushels of corn per acre, 9.6 bushels of wheat and 755 lbs. of hay. On a limed gray-white silt loam soil the manure produced an increase of 25.7 bu. of corn, 8.2 bu. of wheat and 400 lbs. of hay per acre. On the limed Knox silt loam there was an increase of 7.5 bu. of corn, 4.5 bu. of wheat and 1147 lbs. of hay per acre. Data are given showing the effect of manure in different crop rotations. Relatively larger returns were secured with 8.5 tons per acre than with 1.4 tons. The use of phosphate with manure is recommended for the soils under consideration. J. J. SKINNER.

**Calcium arsenite and arsenate as insecticides.** E. B. HOLLANDER AND J. P. BUCKLEY. *J. Econ. Entomology* 11, 354-7(1918).—The scarcity of Pb arsenate will bring into the market cheaper and less reliable arsenicals, such as  $Ca(AsO_3)_2$  and  $CaH_2AsO_4$ . Ca arsenite is fairly sol. in  $H_2O$ , but practically insol. in excess of  $Ca(OH)_2$ . It contains 77.92%  $As_2O_3$ . In spraying tests, however, some foliage injury occurred even when the  $Ca(AsO_3)_2$  soln. was mixed with 3% milk of lime. Calcium hydrogen arsenate was prepared from molar solns. of pure  $CaCl_2$  and pure  $Na_2HASO_4$ , using 10% excess of the latter. The mixed solns. were heated slowly to 95° with agitation, cooled, filtered on a Büchner funnel, washed free of  $Cl^-$ , dried at a low temp. and weighed. The yield was 86%. One mixed sample, prepared in the laboratory, gave the following on analysis:  $CaO$ , 28.344%;  $As_2O_3$ , 58.025%; water of combination, 13.646%. The water-sol. As expressed as  $As_2O_3$  was 44.82%; in lime water soln. the solubility of As as  $As_2O_3$  was 0.17%. CHAS. H. RICHARDSON.

**Blossom spraying and bee poisoning.** JAMES TROOP. *J. Econ. Entomology* 11, 433(1918).—In the lab. 0.000005 g.  $As_2O_3$  was the minimum fatal dose for bees. The field work so far completed indicates that bees may be killed by a poisonous spray at blossom time. The investigations are being continued. CHAS. H. RICHARDSON.

**Plants used as insecticides.** R. C. ROARK. *Am. J. Pharm.* 91, 25-37, 91-107(1919).—A compilation of data. W. G. GAESSLER.

**Attacks of insects on cinchona, tea, etc.** M. KERBOSCH AND CH. BERNARD. *Batavia. Mededeelingen van het Kinaproefstation* IV(1918); *Pharm. Weekblad* 56, 73

(1919).—A description, illustrated with colored plates, of the effects of the red cinchona mite (*Tetranychus bimaculatus*) and the red, orange and yellow tea mites (*Tetranychus bimaculatus*, *Brevipalpus obovatus* and *Tarsonymus translucens*) on cinchona and tea plants. As insecticides,  $(\text{NH}_4)_2\text{SO}_4$  is harmful to the plant, and tobacco ext. is very ineffective. An aq. ext. of the fruit of *Sapindus rarak*, containing a saponin, would be effective but for its extremely slow action. Best results were obtained with S powder. No expts. with HCN are recorded.

JULIAN F. SMITH.

The mode of action of contact insecticides (MOORE) 11L. Fumigation with chloropicrin (MOORE) 11L. Rational utilization of dead animals (FRABOT) 27.

**Insecticide and fungicide.** P. R. JONES. U. S. 1,291,013, Jan. 14. An insecticide and fungicide is formed of 1.5–3 gals. of an emulsified mineral oil containing a small proportion of cresol soap, 5–15 gals. "lime-sulfur soln.," 8–24 oz. of ground glue and 100–200 gals. of  $\text{H}_2\text{O}$ . Bordeaux mixt. may be used instead of "lime-sulfur soln."

**Insecticides.** R. RASMUSSEN. Brit. 121,690, Apr. 23, 1918. An insecticide or disinfectant for the prevention and cure of stem-rot or American canker upon tomatoes and other plants grown under glass and for the extermination of red spider and wire-worm, consists of a mixt. of two parts of bitter aloes with one part of alum and a quarter part of rock salt by wt. Proportions are stated for the diln. of the mixt. according to use.

## 16. FERMENTED AND DISTILLED LIQUORS.

ROBERT WAHL.

**New modes of employment of the Mucedineae in agricultural industries.** P. BAUD. *Chimie et industrie* 1, 699–707 (1918).—Although the distilleries of the North and of Pas-de-Calais were in the hands of the Germans, the production of alc. in 1916 reached 665,232 hl., against 880,821 in 1912. A part of this excellent showing was due to the employment of "mucors" in place of the old style methods (cf. Boulard, *C. A.* 13, 246). The yields from the old process of malting compared with the yields in which mucors are used show an advantage of 14 to 19% in favor of the latter. The transformation of starch into fermentable sugars by treatment with mineral acids gives products yielding a smaller percentage of alc. than by the malting method, and in addition renders the by-products of the industry unfit for cattle food. The origin, structure, and morphology of the Mucedineae, especially "type mucor Boulard No. 5," are described and illustrated with 12 photomicrographs. The technical application of mucors to the manufacture of alc. is given in detail, including a lay-out of the app. on a factory scale. The mucor process is practicable in the first stage of the vinegar industry.

L. W. RIGGS.

Utilization of grape-seed in California (SERRE) 12.

**Distilling alcohol, etc.** SOC. E. BARBET ET FILS ET CIE. Brit. 121,797, June 10, 1914. Addition to 14,041, 1914. The app. specified in the principal patent, for the continuous distn. and rectification of wines and musts, is modified so that it may be transformed at will into a continuous app. for rectifying phlegms.

**Dry wort.** J. G. Ø. MAARDT. Dan. 23,446, Sept. 2, 1918. Sugar and hops are mixed and heated until the mass is caramelized. The hops impart an aroma to the product.

**Beverage.** P. C. SOYEZ. U. S. 1,291,219, Jan. 14. A non-intoxicating beverage is formed by fermenting an infusion of ash-tree leaves containing sugar and tartaric acid, with yeast, and incorporating it with water and chicory to give the desired dilution and a bitterness and color resembling that of beer.

## 17. PHARMACEUTICAL CHEMISTRY.

W. O. EMERY.

**Addition of hypochlorous acid to terpineol.** SLAWINSKI. *Chemik. Polski* 15, 97-105(1917); *Perfumery & Essential Oil Record* 10, 19.—When terpineol is dissolved in AcOH and treated with NaClO soln. (1%) 2 products are formed which can be sepd. by fractional crystn. Both consist of the chlorohydrin of 1,2,8-menthanetriol. The first m. 114-115° and b<sub>18</sub> 162-5°; the second m. 60-80° and b. 125-55°. The crude substance, when treated with KOH (20%), yields a product which seps. into a liquid and a solid portion, m. 118-118.5°. The former, on distn., yields small quantities of pinol and pinol hydrate, which could only be derived from the *cis*-chlorohydrin of 1,2,8-menthanetriol. From the fraction b<sub>18</sub> 175-80° it is possible to isolate *cis*-1,2,8-menthanetriol, m. 118-118.5°. The chlorohydrin of menthanetriol, m. 114-115°, yields almost exclusively pinol hydrate when treated with KOH (20%), so that the Cl atom must be attached to the C atom in position 6. From the mixt. of chlorohydrins, m. 60-80°, only small amts. of the menthanetriol, m. 116-117.5°, could be isolated. The glycerol compd. is, therefore, formed from the chlorohydrin of lower m. p.

E. J. C.

**Effect of morphine concentration on the boiling point method of morphine estimation.** H. E. ANNETT AND H. SINGH. *Analyst* 44, 41-3(1919).—In preliminary tests with quantities of 1 g. and upwards of cryst. morphine, the B. P. method gives accurate results. When only 0.25 g. of cryst. morphine was taken, the method gave low results. Since 8 g. of opium are taken in the B. P. 1914 method, 0.25 g. morphine would correspond to an opium of less than 3% amorphous morphine content. Samples of moist opium well mixed with varying amts. of starch gave results for morphine considerably below the truth. The error of the B. P. 1914 method is stated to be 0.5% morphine either way, in view of which it is concluded from expts. involving reduced quantities of opium and proportionately reduced quantities of reagents that useful results can be obtained by analyzing opium samples when only 4 g., or even 2 g., of the sample are available.

W. O. E.

**Liquor sodae chlorinatae, B. P.** R. C. COWLEY. *Chemist Druggist* 91, 49(1919).—The amt. of Na<sub>2</sub>CO<sub>3</sub> directed by the British Pharmacopeia to be used in the prepn. of soln. of chlorinated soda is insufficient to ppt. the whole of the CaO in soln. and the use of a sufficient quantity for this purpose produces an excessive alkalinity. The following method will allow for variations in the compn. of com. bleaching powders and will produce an approx. neutral soln.: Triturate 50 g. bleaching powder with 500 cc. H<sub>2</sub>O, set aside in a bottle 12 hrs., shaking well occasionally; filter and make up to 500 cc. (A). Dissolve 200 g. cryst. Na<sub>2</sub>CO<sub>3</sub> in H<sub>2</sub>O and make up to 1 l. (B). To 20 cc. of A add 20 cc. dil. HCl, boil to expel Cl, neutralize to Me orange with B, boil to expel CO<sub>2</sub>, and neutralize to phenolphthalein. From the amt. of B required for the 2nd titration the amt. necessary to add to the remaining 480 cc. of A can be calcd. Add the requisite amt. of B, put aside to settle, then filter. The amt. of NaClO in the filtrate should be detd. by the alk. As<sub>2</sub>O<sub>3</sub> method and the strength adjusted to 0.5% wt./vol.

C. O. EWING.

**Assay of theobromine-sodium salicylate.** BAYER. *Pharm. Post* 51, 558(1918); *Schweiz. Apoth.-Ztg.* 57, 36(1919).—Dissolve a 1-g. sample in 10 cc. H<sub>2</sub>O and sat. with

CO<sub>2</sub>. The pptd. HOC<sub>4</sub>H<sub>7</sub>COOH is collected on a tared filter, dried at 100° and weighed. The wt. should not be less than 0.4 g. C. O. EWING.

**Assay of hypophosphites.** BAYER. *Pharm. Post* 51, 335(1918); *Schweis. Apoth.-Ztg.* 57, 35(1919).—Dissolve 20 g. Ca<sub>3</sub>P<sub>2</sub>O<sub>8</sub> in H<sub>2</sub>O and make up to 100 cc. Heat 10 cc. of this soln. on a H<sub>2</sub>O bath with 20 cc. 0.1 N alk. KMnO<sub>4</sub>, cool, acidify strongly with H<sub>2</sub>SO<sub>4</sub>, add a crystal of KI and titrate the liberated I with 0.1 N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>. Not more than 11 cc. should be required, corresponding to a 90% content of Ca<sub>3</sub>P<sub>2</sub>O<sub>8</sub>.

C. O. EWING.

**Detection of formic acid in acetic acid.** BAYER. *Pharm. Post* 51, 393(1918); *Schweis. Apoth.-Ztg.* 57, 35(1919).—The test depends upon the reaction HCOOH + Br<sub>2</sub> → CO<sub>2</sub> + 2HBr. To a soln. of 2–3 g. AcONa in 10 cc. H<sub>2</sub>O. Br water is added until a yellow color is produced, followed by 1–2 cc. of the AcOH to be tested. If HCOOH is present the yellow color disappears; if absent, the color is intensified. The test will detect 0.1% of HCOOH.

C. O. EWING.

**Assay of formaldehyde, hexamethylenetetramine and formalin pastilles.** SRÖWA. *Pharm. Zentralhalle* 59, 27(1918).—See C. A. 9, 952.

E. O. EWING.

**Hyoscyamus niger.** GZO. P. KOCH. *Am. J. Pharm.* 91, 68–82(1919).—Expts. are described on germination of *H. niger* seeds and results are also given of fertilizer and insecticidal tests. Plants of *H. niger* may easily produce 23 grams of seed. The alkaloid content of green hyoscyamus leaves plus seed pods, collected when most of the seed pods had formed, varied in % of mydriatic alkaloids from 0.073 to 0.102. The roots plus the stems contain 0.81% of mydriatic alkaloids. Dry leaves of *H. niger*, collected after harvesting the mature seed, had an alkaloid content varying from 0.057 to 0.065%. Hence, the alkaloid content of the leaves when taken from the plants, when mature and dry, is considerably less than that of those taken from the plants when green. The mydriatic alkaloid content of the stems of the dry plants collected after harvesting the mature seed was from 0.052 to 0.057%. The stems, collected when the plants are green, can probably always be utilized in conjunction with the leaves without failing to meet the total alkaloid requirement of the U. S. P. of 0.0065%.

W. G. GAESSLER.

**The so-called cold process for official soaps.** F. M. JORDAN. *Am. J. Pharm.* 91, 83–5(1919).—J. recommends the following cold processes which yield products in every way meeting the official requirements: *Linimentum saponis mollis* (tincture of green soap): Dissolve 55.90 g. of KOH in 180 cc. of water, and, while still hot, add 279.50 g. of cottonseed oil. Add 180 cc. of alc. and stir or agitate the mixt. until a clear liquid soap results, which should be in about 10 min. Allow to stand for 1 hr., add sufficient alc. thoroughly to liquefy, about 200 cc., and 112.50 cc. of water. Now add 20 cc. of oil of lavender and sufficient alc. to make the finished product measure 1000 cc. Allow to stand 1 week and filter. *Linimentum saponis* (soap liniment): To 53 g. of olive oil, contained in a suitable vessel, preferably of glass, add a soln. of 7 g. of NaOH in 25 cc. of water. To this mixt. add 25 cc. of alc. and agitate the contents of the vessel until sapon. is complete and the mass becomes clear, gelatinous and semi-solid. Let stand 1 hr. or longer. Dissolve 45 g. of camphor and 10 cc. of oil of rosemary in 675 cc. of alc., add to the soap just prepared, and, if necessary, add sufficient water to make the finished product measure 1000 cc. Finally mix thoroughly. *Liquor cresolis compositus* (compound solution of cresol): To 40 g. of NaOH, which must be of full strength, contained in a suitable tared vessel, add 150 cc. of water and stir until soln. has been effected. While still hot, in a thin stream and under const. stirring, add 300 g. of linseed oil. Continue the stirring until the mass acquires the appearance and consistency of an emulsion and set aside, without further stirring, for 12 hrs. or over.

night. To the soap thus formed add 500 g. cresol and sufficient water to make the finished product weigh 1000 g. and stir the mixt. until complete soln. has been effected, which may be hastened, if desired, by the application of gentle heat. NaOH of less than full strength may be used provided its actual strength be taken into account.

W. G. GAESSLER.

Review of the work on essential oils and their constituents in 1914 and 1915.

ANON. *Rev. gén. chim.* 20, 54-65, 70-83(1917); 21, 3-8(1918).

E. H.

A study of cinchona seeds. ANON. *Mededeelingen van het Kinaproefstation V* (Part B); *Pharm. Weekblad* 56, 73-4(1919).—This study includes the influence of temp. and of methods of sampling on the analysis of cinchona seeds. Studies on germination showed that moisture is very harmful. Failure of government seeds, however, is more often due to mites than to moisture. The secrecy practiced by many analytical labs. is severely criticized. (Part A of number V contains the report of the Cinchona Expt. Sta. for 1916-17.)

JULIAN F. SMITH.

Preparation and preservation of powdered myrrh which gives Bonastre's reaction. CHRISTENSEN. *Arch. Pharm. Chemie* 1918, 230-4, 245-53; LOFF, *Ibid* 1918, 265-7; *Schweiz. Apoth.-Ztg.* 56, 665-6(1918).—A Danish prize problem to det. whether powdered myrrh can be readily prepd. or kept so as to retain the property of giving Bonastre's Br test, eventually modified. C. crushed 300 g. of myrrh finely and left it over CaO for 2 weeks. After sieving it was dried again for 2 weeks, then powdered and passed through a fine sieve. It gave the test with Br and with HNO<sub>3</sub>. When kept in filled and corked vessels in the dark, the test was positive after 10 months, while in partly filled, glass-stoppered vessels kept in daylight, the test was faint after 6 and negative after 10 months. The same powder in contact with O in a well sealed bottle failed to give the test after 6 weeks, due to oxidation of the essential oil. C. obtained 8.76% of oil by distn. with steam, and 7.41% by extn. with petroleum ether. The consts. of the 2 oils were, resp.,  $d_{4}^{20}$  1.0132, 0.9664;  $n_D^{20}$  1.4979, 1.5140;  $[\alpha]_D^{20}$  -44.66;  $[\alpha]_D^{17}$  -50.03 (in Et<sub>2</sub>O), -49.79 (in CHCl<sub>3</sub>); b p. about 260°. It contained 80.82% C and 9.51% H. C. prefers Greenish's test of Germ. Pharm.V. L. finds Bonastre's test positive after prolonged contact of the powder with N in place of air, also that the oxidized oil is sol. in C<sub>6</sub>H<sub>6</sub> and CHCl<sub>3</sub>, not in Et<sub>2</sub>O, EtOH or CS<sub>2</sub>. He recommends that the Pharm. Danica replace Et<sub>2</sub>O by CHCl<sub>3</sub> in the test.

S. WALDBOTT.

Research and the United States Pharmacopeia. A. H. CLARK. *J. Am. Pharm. Assoc.* 8, 13-6(1919).

L. E. WARREN.

Some variations in cinchona bark and its preparations. H. H. SCHAEFER. *J. Am. Pharm. Assoc.* 8, 11-3(1919).—The U. S. P. IX requires a standard of 5% of total alkaloids in cinchona. The U. S. P. VIII required 5% of total alkaloids but also specified 4% of ether-sol. alkaloids. Owing to restricted shipping facilities due to the war, much low-grade cinchona has been on the market during the last year or two. Some of this bark conformed to the U. S. P. IX standard but would not meet the requirements of the U. S. P. VIII in ether-sol. alkaloids. Five specimens assayed 5.32, 5.83, 6.01, 5.52 and 5.08% of total alkaloids while the ether-sol. results were, resp., 3.42, 2.92, 3.01, 2.98 and 2.67%. A number of market tinctures of cinchona were examd. to det. whether they had probably been made from such questionable bark. Most of the tinctures passed the requirements of both pharmacopeias. Three samples assayed 0.912, 0.954, and 0.983 g. of total alkaloids and, resp., 0.64, 0.59 and 0.49% of ether-

sol. alkaloids per 100 cc. Likewise a number of fluid exts. of cinchona were assayed by both standards. Three gave 4.61, 4.23 and 4.01 g. of total alkaloids and, resp., 3.20, 3.01 and 2.92 g. per 100 cc. of ether-sol. alkaloids. It is concluded that the standards of the U. S. P. IX are actually lower than those of the U. S. P. VIII. S. believes that both standards should be required. L. E. WARREN.

**The functions of the engineer: His education and training.** W. A. J. O'MEARA. *Electrician* 82, 198, 229(1919).—Among the points discussed is the need for the statutory control of the engineering profession, a control such as exists in the case of the medical and legal professions. C. G. F.

**Chemical industry in Turkey.** G. FÉSTER. *Rev. prod. chim.* 22, 39-42(1919). E. H.

**Some observations on sulfuric acid plants (new and old).** VIII. "P." *Gas World* 70, No. 1802 (Coking and By-products Sec.), 17-8(1919).—A review of some earlier methods for regenerating spent oxide and recovering S. J. L. W.

**Notes on the Bucher cyanide process for the fixation of nitrogen.** EUGEN POSNJAK AND H. E. MERWIN. *J. Wash. Acad. Sci.* 9, 28-30(1919).—Crude technical products of this process show some bearing constituent other than ordinary NaCN. Checking B.'s work, the authors obtained concordant results, confirming the reaction as given by him. Investigation of the chem. nature of the N-bearing material in the crude product is being continued. T. E. KRITT.

**The alunite problem.** W. F. DOWNS. *Eng. Mining J.* 107, 388(1919).—A general discussion in which the author points out that the recovery of  $K_2O$  and  $Al_2O_3$  from alunite is rendered complex and difficult by the accompanying impurities. None of the new methods proposed for recovering both  $K_2O$  and  $Al_2O_3$ , has a record of production; however, enough has been done under one of them to indicate that it is of com. value. In this process some base is mixed with the crude alunite and the mixt. heated. When the resultant salts are thus formed, the  $Al_2O_3$  and silicates and  $SiO_2$  in the mass can be sepd. from all sol. sulfates by lixiviation, and the  $K_2O$  recovered from the soln. The  $Al_2O_3$  can then be sepd. by any one of several methods. The special features are: recovery of nearly all of the  $K_2O$ , recovery of 90% or more of the  $Al_2O_3$ , and the high grade of the  $Al_2O_3$  produced (99.5%  $Al(OH)_3$ ). F. W. SMITHER.

**Production and uses of salt peter.** H. S. GALE. *Eng. Mining J.* 107, 385-8(1919).—An account of the history, uses, and sources of  $KNO_3$ , with notes as to its availability for more extensive application as a fertilizer. Reference is made to the important method recently adopted in Chile for isolating a comparatively high grade  $KNO_3$  from the mother liquor which circulates in the Chilean nitrate plants. F. W. SMITHER.

**Extracting helium from natural gas.** G. A. BURRELL. *Oil & Gas J.* 38, 50, 55(1919).—An historical review of the discovery of helium. The properties are shown as particularly adapted to balloon use. He was first noted in Kansas natural gas in 1907, from a trace to 1.84%. It was found in considerable amt. in gas from the Petrolia Field, Texas, in 1917. Three plants were erected there by the Government; all use some form of liquefaction. All constituents except He are liquefied and removed

from the gas. Natural gas should contain at least 0.5% of He; better results can be obtained if the amt. is larger.

R. R. MATTHEWS.

**Method of handling phosphorus.** BERTRAM BLOUNT. *Analyst* 43, 291-2 (1918). —In handling P in cases in which water cannot suitably be utilized, "N in liberal quantities and free from O can be used with safety." CO<sub>2</sub> is not satisfactory for this purpose.

E. J. C.

---

**Sulfuric acid.** H. M. WEBER. U. S. 1,291,306, Jan. 14. In making H<sub>2</sub>SO<sub>4</sub> of 98% strength, SO<sub>2</sub> is passed into H<sub>2</sub>SO<sub>4</sub> of 100% strength until at least 5% of additional SO<sub>2</sub> has been taken up, and this acid is then dild. to the desired strength.

**Nitric acid.** C. TONIOLO. Brit. 121,635, Dec. 27, 1917. In the manuf. of HNO<sub>3</sub> by absorbing N oxides in H<sub>2</sub>O in a series of towers in counter-current, strong cooling of the acid passing from tower to tower is effected by artificial refrigeration so that the acid entering each tower may be in the neighborhood of its f. p.; e. g., the acid entering the last tower may be at 4-5°, that entering a preceding tower receiving 13% acid, -8°, and in an earlier tower receiving 65% acid -25°.

**Ammonia, cleansing compositions.** G. WOLFF. Brit. 121,576, Mar. 21, 1918. Org. waste products such as seed cakes, horse flesh and residues thereof, fruit pips, glue residues, and nitrated vegetable products are treated with alk. solns. to recover NH<sub>3</sub> and to obtain a product having detergent properties.

**Ammonium perchlorate; sodium bicarbonate.** D. AANENSEN. Brit. 121,727, Oct. 30, 1918. NH<sub>4</sub>ClO<sub>4</sub> is produced by reacting upon NH<sub>4</sub>NO<sub>3</sub> with NaClO<sub>4</sub> in the presence of H<sub>2</sub>O; the pptd. NH<sub>4</sub>ClO<sub>4</sub> is sepd., and the soln. of NaNO<sub>3</sub> is treated with NH<sub>4</sub>HCO<sub>3</sub> or NH<sub>3</sub> and CO<sub>2</sub> to cause the pptn. of NaHCO<sub>3</sub>; the soln. of NH<sub>4</sub>NO<sub>3</sub> after the removal of the bicarbonate is then used for reaction with a further quantity of NaClO<sub>4</sub>.

**Chromium and iron salts; dyeing; tanning.** T. J. I. CRAIG and P. SPENCE & SONS. Brit. 121,617, Oct. 26, 1917. Mixed solns. of chromic and ferric salts, for use in dyeing, tanning, etc., are prepd. by treating solns. of chromic acid compds. with Fe or reducing compds. of Fe; the acidity of the soln. may be adjusted to give acid, neutral,

or basic products. According to the reducing power of the Fe compd. or Fe used, the mol. ratio of Cr to Fe in the products is greater than, equal to, or less than unity. Examples of the reduction of  $\text{Na}_2\text{Cr}_2\text{O}_7$  soln. by Fe pyrites, metallic Fe, and  $\text{FeCl}_2$ , all in the presence of HCl, are given; FeS and  $\text{FeSO}_4$  also are specified as reducing agents. Cf. 4,890, 1896, 14,052, 1897, 5,902, 1903, and 16,887, 1907.

**Magnesium carbonitride.** E. W. HASLUP. U. S. 1,291,498, Jan. 14. A Mg carbonitride is produced in a blast furnace by charging the furnace with a mixt. consisting essentially of MgO and C (the C being in sufficient excess to insure the maintenance of a reducing atm. in the furnace at all times), heating the charge to a temp. at which carbonitride is formed (preferably about  $1600^\circ$ ) and withdrawing the product from the reaction zone as fast as it is formed.

**Waterproof adhesive.** S. BUTTERMAN. U. S. 1,281,396, Jan. 14. An adhesive suitable for use for some time after prepn. is formed of casein 1,  $\text{H}_2\text{O}$  2.90, hydrocarbon oil 0.015,  $\text{Ca}(\text{OH})_2$  0.15, and Na silicate 0.70 parts.

**Plastic compositions.** C. F. CURTIS. Brit. 121,855, Feb. 19, 1918. The dust left after burning Fe, Cu, or arsenical pyrites is used as an ingredient in a mixt. for an acid-proof compn. The mixt. is: sawdust 30%, portland cement 30%, pyrites residue 30%, whiting 10%. The mixt. is moistened and is applied as a lining or shaped by molding.

**Cleansing and abrading compositions.** NORTON CO. Brit. 121,721, July 11, 1918. To an abrasive composed of cryst. alumina contg. up to 8% of an acid oxide, such as  $\text{SiO}_2$  or  $\text{TiO}_2$ , is added alkali, such as soda, in sufficient quantity to neutralize the acid wholly or in part. The resulting compn. is stated to be less tough and more suitable as an abrasive.

**Dentifrices; polishing powders.** L. V. SLAUGHT. Brit. 121,592, Nov. 12, 1918. A cleansing and polishing powder which may be used in dentifrices, metal polishes, etc., and which consists of amorphous, structureless cellulose or cellulose hydrate, is prepd. by treating viscose soln., preferably freshly prepd., with a salt soln. such as  $\text{CaCl}_2$  or  $\text{NaHSO}_3$  soln., or a mixt. The gelatinous ppt. is washed preferably with  $\text{H}_2\text{O}$  rendered alk. with  $\text{NaHCO}_3$  or other salt and is dried and ground. Some unaltered cellulose fibers may remain in the powder or may be added. An antiseptic, germicide, or medicament such as phenol, cresol, or xyleneol, which may be emulsified with soap, gelatin, gum or sol. oil, or a soln. of HCHO in essential oil, or of Cl in paraffin oil or an essential oil such as oil of lavender, bergamot, etc., may be incorporated in the powder, by spraying the liquid into a moving stream of the powder.

## 19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLEININGER.

**Observations on apparent causes of failure in lead glass pots.** A. F. GORTON. *J. Am. Ceram. Soc.* 1, 648-59 (1918).—Cracking and corrosion are the chief causes of failure. Cracks are due to strains set up by (1) too rapid heating in the arch, (2) insufficient preheating, (3) throwing in the glass batch. Corrosion is due to slagging caused by Fe impurity and to soln. in the fusing alkali and molten glass. Inability properly to burn the pot bottom during arching causes rapid corrosion. The glaze due to a surface coating of glass or to heating the surface with an oil burner affords but little protection. Lining with a porcelain or high-Al material is likely to fail because of cracking away of the lining. A safer method is to burn the pot thoroughly to  $2500^\circ$  F. Adding porcelain as grog is of little use; it increases tendency to bulge. Some material better than fire clay is needed.

C. H. KERR.

**The identification of "stones" in glass.** N. L. BOWEN. *J. Am. Ceram. Soc.* 1, 594-605(1918).—Stones may be (1) pot stones, (2) batch stones, (3) crown drops, (4) devitrification stones. Chem. analysis for purposes of identification is usually made difficult by the small size of the stones and the contamination of the surrounding glass and analysis is apt to be unsatisfactory. The petrographic microscope is preferable. Powdered samples are quite satisfactory. *Pot stones* are seen to be "in all cases crystals of sillimanite with a little interstitial glass." Sillimanite is never found in stones of other origin. Evidently the glass in acting on the pot material first dissolves in excess  $\text{SiO}_2$  above that required to form  $\text{Al}_2\text{SiO}_5$ . *Batch stones* are unassimilated sand. The  $\text{SiO}_2$  is found in several forms. Frequently the core is unaltered quartz surrounded by a layer of cristobalite or a mixt. of cristobalite and tridymite. *Crown drops* are of  $\text{SiO}_2$  but are distinguished from batch stones by almost complete conversion to tridymite (and usually large crystals compared with the fine-grained cristobalite of batch stones). *Devitrification stones* appear in various forms. Spheruloidal cryst. masses are common forms.  $\text{SiO}_2$ , the most common glass constituent, is perhaps the commonest in sepg. out, usually in tridymite form with some cristobalite. The spherulite appears solidly cryst. but the interstitial glass between the radiating cryst. fibers greatly predominates. "A spherulite grows entirely at the expense of the glass contained within it" and the glass outside the spherulite is unaffected.  $\text{CaSiO}_3$  seps. out as wollastonite. Other crystals that sep. out are  $\text{BaSi}_2\text{O}_7$  and  $\text{PbSiO}_3$ . The optical properties of these crystals are briefly given.

**Some aspects of the scientific glassware industry.** F. W. BRANSON. *J. Soc. Chem. Ind.* 37, 337-407(1918); cf. *C. A.* 9, 2134.—Numerous analyses and tests show that 7.5-8.5%  $\text{ZnO}$ , about 6.5%  $\text{Al}_2\text{O}_3$  and about 7%  $\text{B}_2\text{O}_3$  will give a good glass for this use if the  $\text{SiO}_2$  and alkali are properly proportioned. Regarding  $\text{CaO}$  it is found that if  $\text{ZnO}$  is reduced  $\text{CaO}$  is the best substitute. A glass with 6%  $\text{Al}_2\text{O}_3$  gives increased strength and attacks the pot less. Lab. glassware should be standardized as to sizes and shapes and a committee to accomplish this is urged. Reannealing at  $580^\circ$  after a first annealing at  $580^\circ$  gave a better annealed and more resistant product. This should be studied further.

C. H. KERR.

**Crushing strength of magnesia-silica mixtures at high temperature.** O. L. KOWALKE and O. A. HOUGEN. *Trans. Am. Electrochem. Soc.* 33, preprint.—Magnesia and silica of high purity were mixed in varying proportions, baked at various temps. and cylinders of the mixts. were subjected to pressure in an elec. furnace. The pressure was applied by a C rod at carefully measured temps. When subjected to a definite applied pressure, the temp. at which they crushed was noted. A mixt. containing 7.5%  $\text{SiO}_2$  failed at about  $1870^\circ$ , which was  $190^\circ$  higher than magnesia supported. The superiority of this mixt. appeared to be due to the envelope of forsterite which cemented the grains of periclase and failure is due to a softening of the forsterite. Above  $2000^\circ \text{C}$ . attacked magnesia-silica mixts. very rapidly. The elec. furnace and the arrangement of the cylinder for test are illustrated and photomicrographs support the theory of the formation of compds. between  $\text{MgO}$  and  $\text{SiO}_2$  at the various temps.

C. N. WILEY.

The solubility of portland cement and its relation to theories of hydration. J. C. WITT AND F. D. REYES. *Philippine J. Sci.* 13A, 147-61(1918).—When cement is shaken in  $H_2O$  in a closed vessel large amts. of Ca go into soln. When 8000 parts of  $H_2O$  are used, 90% of the Ca present goes into soln. within 24 hrs. The results show close relation to accepted theories of hydration. Soly. of Ca is affected by the presence of  $CO_2$ , method of agitation, fineness of grain, vol. of  $H_2O$ , and time. It was not found possible to obtain a satd. soln. of  $Ca(OH)_2$  by shaking cement with  $H_2O$ . Contrary to the accepted theory, the authors claim their expts. indicate that excess of gaging  $H_2O$  produces greater hydration and greater strength. By adding excess  $H_2O$ , then evapg. to the amt. indicated by normal consistency tests, and molding, briquets increased in strength as the amt. of  $H_2O$  increased.

C. N. WILEY.

Tentative specifications for C 14-18T-cement-concrete sewer pipe. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 555-66(1918).—Directions are given for crushing, hydrostatic pressure and absorption tests.

Compressing concrete increases its strength. F. P. MCKIBLEN. *Eng. News-Record* 81, 1031-4(1918).—Results are shown for comparison of compressive tests on concrete columns of 1:2:4 concrete and "compressed concrete" columns made similarly of 1:2:4 concrete but compressed during the process of molding with loads varying from 25,000 to 40,000 lbs. All columns were approx. 5 ft. long and 14 in. wide. The compressed concrete averaged 153 lbs. per cu. ft., about 4% higher than the ordinary concrete. Each compressed column was molded in 5 layers, about 12 in. deep, the pressure being allowed to remain on each successive layer for a few min., the plunger being then withdrawn and the next layer spaded in the form and compressed. For 28-day ordinary columns the av. compressive strength is 1774 lb. per sq. in., for compressed column with a load of 25,000 lbs. 2255 lbs. per sq. in., for 30,000 lbs., 2,540 lbs. per sq. in., and for 35,000 lbs. 2,780 lbs. per sq. in.

Sampling of deposits of road stone and gravel in the field. L. REINECKE AND K. A. CLARK. *Proc. Am. Soc. Testing Materials* 18, Pt. II, 393-415(1918).—Methods are outlined for sampling and testing bed-rock and boulder aggregates or gravel suitable for use in road work. H. A. BRIGHT.

Abrasion test for stone gravel and similar aggregates. H. H. SCOFIELD. *Proc. Am. Soc. Testing Materials* 18, Pt. II, 416-28(1918).—In the standard Deval test for road materials the retention of dust tends to misleading results. A new machine designed to eliminate this objection has given better results. H. A. BRIGHT.

Report of committee C-4 on clay and cement sewer pipe. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 274-80(1918). H. A. BRIGHT.

Tentative definitions of terms relating to the gypsum industry. *Proc. Am. Soc. Testing Materials* 18, Pt. I, 592-611(1918). H. A. BRIGHT.

Effects of grading of sands and consistency of mix upon the strength of plain and reinforced concrete. L. N. EDWARDS. *Proc. Am. Soc. Testing Materials* 18, Pt. II, 303-16.—A supplementary paper (cf. C. A. 11, 3409). The one-yr. tests supply these further conclusions: (1) the increment of strength developed between the age of 90 days and one year is not const. and cannot be predetd., and in wet concrete this increment is almost negligible; (2) the results obtained in the consistency-abrasion test indicate that the excess water in an over-satd. concrete reduces its resistance to abrasion and shock. H. A. BRIGHT.

Effect of age on concrete. D. A. ABRAMS. *Proc. Am. Soc. Testing Materials* 18 Pt. II, 317-35(1918).—A study of a large no. of test data on the strength of briquets and mortars was made to investigate the laws governing the change in strength of concrete. Age-strength relations for tension tests of 1 to 3 standard sand mortars indicate that slight retrogression in strength occurs after ages of 3 to 6 mos. There is, however, a different age-strength relation found for concrete when tested in compression. Plotting results with compressive strength as ordinates and age of tests (logarithmic scale) as abscissas the path of the lines is expressed by the equation  $S = n \log a + K$ , where  $S$  = compressive strength,  $a$  = age of test, and  $n$  and  $K$  are consts. whose values depend on the quality and other conditions of the test. The diagrams show that the strength of concrete seems to increase indefinitely so long as it does not dry out. If the concrete becomes wet only due to exposure to the weather, the change in strength is much slower than if the concrete is continuously satd. with water. H. A. B.

DWARS, A. W. C.: Beton en gewapend beton. Beknopte handleiding bij middelbaar technisch onderwijs, tevens ten dienste van kandidaten voor het diploma bouw-kundig opzichter en technisch ambtenaar. R. W. Utrecht: A. E. Kluwer te Deventer. 71 pp. f 1.60. For review see *Chem. Weekblad* 16, 128(1919).

Cements. B. BAARNHIELM. *Brit.* 121,728, Oct. 30, 1918. Ground ashes of burnt alum-slate are mixed with portland cement. The proportion may be of equal parts or the ashes may be in greater proportion.

## 21. FUELS, GAS, TAR AND COKE.

J. D. PENNOCK.

The production of coal and coke in Canada during the calendar year 1917. JOHN MCLEISH. Can. Dept. Mines, Mines Branch, *Adv. Chapter of the Annual Rept. on the Mineral Production of Canada during 1917*, No. 501, 39 pp.(1919); cf. C. A. 12, 1345. E. J. C.

**Oxidation of coal.** J. R. PARTINGTON. *Chem. News* 118, 50-1(1919).—P. criticizes the deductions drawn by Wheeler (cf. *C. A.* 13, 651) and suggests another hypothesis to explain W.'s results. From a mixt. of gases in contact with freshly hewn coal deprived of its occluded gas, adsorption takes place on the surface of the coal. Owing to preferential adsorption of moisture, permanent gas adsorption with dry air should be greater than with moist air. The adsorbed layer of gas reacts with the coal to produce CO and CO<sub>2</sub>. The pressure of the air brought in contact with the coal falls rapidly for a short period and then gradually until adsorption equil. is reached. The primary product of the reaction which then begins is CO alone. CO<sub>2</sub> is produced by a secondary reaction involving moisture. CO<sub>2</sub> is produced either by the interaction of CO with water, the latter acting as a catalyst, or by the direct interaction of adsorbed moisture with C. The H produced may be wholly reoxidized, retained on the adsorbent, or traces may escape. P. takes up the different points brought forward by W. and shows how the adsorption hypothesis explains results more fully, and without the assumption of any hypothetical chem. compd. A. G. BLAKELEY.

**"Sandwich" system of fuel blending.** E. W. L. NICOL. *Gas J.* 145, 113(1919); *Gas World* 70, 58-9(1919).—The "Sandwich" system of fuel blending, as devised by N. and practiced by several fuel users, consists in feeding 2 solid fuels, such as bituminous coal and coke, on to a mechanical stoker from a double hopper so that the fuel enters the furnace in well-defined superposed layers, the coal being on top. The volatile gases given off from the latter maintain the fire-brick ignition or coking arch in an incandescent state, thus establishing positive and continuous ignition at the point of entry on the grate. With a simple and intimate mixt. of coal and coke in any considerable proportion, it has been found impossible to maintain these essential conditions as the arch gradually cools and misfiring occurs. By this system of blending, solid fuels having different physical and chem. properties can be blended so as to improve the efficiency and intensity of combustion to a considerable extent. Some successful experiences suggest the possibility of utilizing as a primer for coke the various low-grade and waste fuels which are ordinarily hard to utilize in any way. Some actual working results obtained by using coal slack and unscreened broken coke as compared with coal alone under exactly similar conditions on the same B. & W. boiler and economizer are, resp.: calorific value as fired, 11138-12150 B. t. u.; fuel consumed per grate ft. hr., 30.66-31.66 lbs.; av. steam pressure, 178-179 lbs.; water evapd. per lb. of fuel, 7.18-5.76 lbs.; efficiency, 79.96-60.98%. J. L. WILEY.

**Motor fuel.** G. K. GJERDE. *Papier Journalen* 1918, No. 6, 42.—Comparison between the advantages and disadvantages of various kinds of motor fuel, acetylene gas, gasoline, sulfite alc., etc. It is shown that sulfite alc. is the best substitute for gasoline. To facilitate the starting up of the motor about 20% C<sub>6</sub>H<sub>6</sub> or other suitable hydrocarbon should be added to the alc. Even coal oil can be added advantageously, notwithstanding the fact that coal oil and alc. do not commingle completely.

G. HALLBERG.

**Institution of gas investigation committee.** JAMES W. WOOD. *Gas J.* 145, 167-9 (1919).—Reply to criticisms (cf. *C. A.* 13, 507). J. L. W.

**Natural gas: its production, service and conservation.** SAMUEL S. WYER. U. S. National Museum, *Bull.* 102, Pt. 7, 66 pp.(1918).—The fundamental principles of natural gas production, transmission and distribution are discussed. Special emphasis is placed on the wasteful methods employed in connection with the utilization of natural gas, and a plea is made for greater public interest in the enforcement of methods for conserving it. J. L. WILEY.

**The future of gas producers and their utilization of fuel.** G. MARCONNET. *Chimie*

& industrie 2, 6-14(1919).—A plea for more intensive and economical utilization of inferior fuel resources by gasifying in gas producers with recovery of by-products.

J. L. WILEY.

Discussion, from the chemical viewpoint, of E. Körting's lecture on the economic status of the gas industry. H. BUNTE. *J. Gasbeleucht.*, Aug. 24, 1918; *Hel Gas* 38, 283-7, 297-301.—Various phases of the gas industry are discussed, with particular emphasis on the question of coal supply. Lignite in Germany, and peat and wood in surrounding neutral countries, were much used in gas plants during the war; but in normal times no fuel can compete with good gas coal for this purpose. Increasing the yield of gas, by dilg. with water gas to a heat value of 4700 calories is not advisable either from the producers' or the consumers' standpoint. There is much need of further study of methods of increasing the gas yield. JULIAN F. SMITH.

Operation and chemical control of water gas sets in small plants. H. VITTINGHOFF. *Am. Gas Eng. J.* 110, 163-4(1919); *Gas Record* 15, 109-12(1919).—Some essential points to observe in operating small plants are discussed. Regularity of operation is necessary for economical operation; the set should be cleaned once every 12 hrs. at least, and preferably once every 8 hrs.; the interval between the charging of the generator should not exceed an hour or embrace a max. of more than 8 runs; the blow and run should be started and the oil introduced strictly on a carefully worked out schedule. The use of pyrometers is essential to regulate the temp. of the carburetor and superheater, the proper temp. of course depending on the individual machine, the location of the sensitive ends of the thermocouple and upon the quality of oil to be carbonized. Usually a temp. between 1340 and 1380° at the bottom of the superheater and about 1340° at the top results satisfactorily. Two methods for controlling the temp. are: varying the vol. of blast, or varying the period of the blast while the vol. is kept const. Usually, the latter method is followed, the length of the blow being increased or decreased, depending upon the conditions, care being taken, however, not to decrease the period below a certain point nor during a number of consecutive cycles as this results in a low temp. of the fuel in the generator and an increased production of CO<sub>2</sub>. In injecting oil into the carburetor, it often happens that the excessive heat of the upper layers of the checker brick breaks down the oil into C and H. This can be prevented by introducing steam into the generator so that the blue gas formed may absorb some of this heat before the oil is introduced. It is also important to consider the amt. of air, steam and oil used. Experience has shown that 1500-1700 cu. ft. of generator air per thousand cu. ft. of gas will result in a hot fire, proper temp. in carburetor and superheater for distn. and carbonization of the oil, and an economical fuel consumption. It has also been found that 35-38 lbs. of steam per thousand cu. ft. of gas will yield a blue water gas free from an excessive amt. of harmful CO<sub>2</sub> and at the same time load the set up to its most economical rate of production. In order to operate a plant efficiently expert supervision and chemical control are necessary. The raw materials should be carefully analyzed for quality and the operation varied accordingly, and frequent systematic observations should be taken of the finished gas as well as the intermediary blue water gas, producer gas and waste gas. The CO<sub>2</sub> should be reduced to a minimum, not in excess of 4%. But even if the finished gas does contain CO<sub>2</sub> not in excess of this amt., it does not necessarily indicate that the operation is being carried on economically, for often the blue water gas as produced in the generator contains an excessive amt. of CO<sub>2</sub> which on contact with the oil injected in the carburetor is reduced but at the expense of economy. The excess of CO<sub>2</sub> may be due to either too much steam relative to the heat available in the fuel bed, or improper rate of steam introduction. Having given a fixed wt. of incandescent fuel, the quality of blue gas depends upon the amt. of steam introduced per min. and upon the temp.

of the body of fuel at various instances during the run. Having detd. the total amt. of steam which can be introduced per run, it can be assumed that in a 4-min. run, 65% should be introduced the first 2 mins, 20% in the third and 15% in the last. Good practice seems to indicate that the blue water gas as made at first should contain about 3% CO<sub>2</sub>, which may increase to 4.5% during the middle period and not to exceed 7% during the last minute. An excess of steam injected is not only an expensive waste of boiler fuel but also results in poor generator fuel economy and oil results. A large amt. of steam will not necessarily result in a large make of gas per hr. nor will a small amt. give good results since the capacity of the set is reduced, thus requiring larger labor expense, and serious clinker troubles may result, requiring added cleaning and heavy wear on the linings of the machine. In obtaining a proper balance between CO<sub>2</sub> and CO in the producer gas, the rate and amt. of air flow through the generator must be regulated. A relatively high rate of flow tends toward a production of large amts. of CO<sub>2</sub>; therefore it is desirable to introduce the air during as short a blow as feasible in order to obtain as high a rate of flow as possible. Samples should contain about 14% CO<sub>2</sub>. During the run CO<sub>2</sub> increases on account of the decreasing temp. of the fuel bed; the opposite is true during the blow, CO being formed in increasing quantities, as the temp. increases. This fact must be considered in handling the carburetor blast valve so that the secondary air introduced into the carburetor should be in proportion to the amt. of CO available, increasing from a minimum at first to a max. at the end. It is better to have an excess of secondary air than a deficiency permitting unconsumed amts. of CO to escape at the stack. In regard to chemical control of the waste gases, analysis of a composite sample taken during 5 or 6 consecutive blows should show CO<sub>2</sub> 18-19%, O<sub>2</sub> 0.5-1%, CO 0.3-0.4%. An excess of O would mean too much carburetor blast, while an excess of CO would indicate the reverse. J. L. WILBY.

**Village gas works—new gas-making process.** C. B. TULLY. *Gas J.* 145, 215-6 (1919); *Gas World* 70, 71(1919).—In order definitely to prove the possibilities of a low-grade gas of 350-400 B. t. u. for distribution on practical lines, a small plant was installed at Kingscliff to produce such a gas from non-caking hard coal by completely gasifying the fuel and producing the max. quality of gas from a minimum of coal, at the same time avoiding the necessity of marketing residuals. Coal, coke, a mixt. of the two, or a mixt. of coke and peat, can be satisfactorily used. The gas has satisfied all requirements both for domestic and industrial uses with more economy and simplicity than ordinary coal gas. Only slight adjustments on burners and fittings were required. The plant consists of a small generator, wash box, vertical steam boiler and engine and blower. The gas from the wash box passes direct to the existing plant through the foul main, condensers, scrubber, oxide purifiers and meter into the gas holder. The plant makes 2000 cu. ft. per hr., and produces 40,000 cu. ft. of 400 B. t. u. gas per ton of coal. The only labor required is that of a boy of 16 yrs. who has charge of the whole plant, which operates only 4-5 hrs. per day. J. L. WILBY.

**Vertical retort steaming tests at Springfield.** L. J. WILLIEN. *Gas Age* 43, 232-3 (1919); *Am. Gas Eng. J.* 110, 211-3(1919).—The process of steaming, as practiced since 1906 by the Springfield, Mass., Gas Light Co. in Dessau vertical retorts, consists in introducing steam at the bottom of the retorts during the last 2 hrs. of the carbonizing period. By using steam in this way the yield of gas is increased about 20%, the candle power is reduced 25%, and the B. t. u. 8%. The temp. of the incandescent C has a direct bearing on the amt. of blue water gas formed. At 1240° F. 8.8% of the steam was decomposed, yielding a gas consisting of 65.2% H, 4.9% CO and 29.8% CO<sub>2</sub>, whereas at 1960° F. 99.4% of the steam was decomposed with a gas showing 50.9% H, 48.5% CO and 0.6% CO<sub>2</sub>. In 1917, tests were made on 1 unit of the Glover-West continuous vertical retorts, consisting of 24 retorts, operating 1 week with steam

and 1 without steam, the steam being admitted continuously. Steam connections were made at the top of the casting connected to the bottom of the retort by a  $\frac{1}{4}$  in. line. In order to obtain an equal distribution of steam into each retort, a valve and a disk with a  $\frac{1}{4}$  in. orifice were installed at the inlet. The amt. of steam used was measured by placing a disk with a  $\frac{1}{2}$  in. orifice in the main steam supply line and pressure gages on both sides of the disk, the steam pressure being kept const. by means of a pressure regulator on the high pressure side. Steam superheated to about  $200^{\circ}$  F. was used to the amt. of 8400 lbs. per day or 350 lbs. per retort. The pressure was regulated to 20 lbs. Operating results with and without steaming, resp., show a yield per cu. ft. of 6.72 and 5.49, or 22.4% gain; B. t. u. per cu. ft. 519 and 540, or 3.8% loss; c. p. 7 and 9.5, or 26.3% loss. The av. no. of retorts out per day for scurfing was 43.7% less with the steam than without. The formation of C on the sides of the retort was reduced between 40 to 50%, that formed being of an amorphous nature and easily removed. The gas analyses indicate an improved quality of gas. The % compn. with and without steaming, resp., was as follows:  $\text{CO}_2$  1.69-1.23,  $\text{C}_2\text{H}_4$  1.65-1.07,  $\text{C}_2\text{H}_2$  0.95-0.97,  $\text{O}_2$  0-0,  $\text{CO}$  11.16-7.92,  $\text{CH}_4$  24.67-27.33,  $\text{H}_2$  56.18-57.69,  $\text{N}_2$  3.7-3.8. The production of  $\text{NH}_3$  was increased about 12%. The coal used showed about 35% volatile, 8% ash and 1.5% S. There was practically no loss in coke. W. concludes that steam may be used to advantage with through horizontals or inclined retorts, with probably a smaller yield, however.

J. L. WILEY.

**Discrepancies between observed and calculated values of combustible gases.** NORTON H. HUMPHRYS. *Gas World* 69, 314(1918).—The differences noticed in comparing the observed and calcd. values of combustible gases are of no real importance and usually may be attributed to variations in accuracy of app. employed and in the arbitrary values given for hydrocarbons other than  $\text{CH}_4$ , which may be fairly const. with some systems of manuf. but vary widely with others. With straight coal gas of av. quality, produced by hand stoking and horizontal retorts, the difference is usually about 20-25 B. t. u., but it is more erratic with verticals, especially with steaming. Blue gas made from gas coke by the cupola process is about the same as coal gas but the difference rises with the degree of carburization to 50 B. t. u. or more in favor of the observed test. With rich oil gas the difference is greater. It is evident that anything like a complete agreement between observed and calcd. calorific values can be only a matter of luck.

J. L. WILEY.

**Composition of luminous gases as affecting air complement.** NORTON H. HUMPHRYS. *Gas World* 69, 346(1919).—H. attempts to establish values for the compn. of hydrocarbons other than  $\text{CH}_4$  in gas which contributes to the production of heat. He recommends that there be prepd. a standard table of calorific values for each of the constituents concerned, the conditions of pressure, temp., satd. or dry, etc., being clearly defined. (Cf. following abstract.)

J. L. WILEY.

**Composition of illuminating gases as affecting air complement.** G. NEVILL HUNTLEY. *Gas World* 70, 34(1919).—A criticism (cf. preceding abstract). J. L. W.

**Valuation and methods of analysis of spent oxide.** HAROLD G. COLMAN AND E. W. YEOMAN. *Gas J.* 145, 68-9, 112-3, 169-70(1919).—A review of some analytical methods of estg. free S, CN compds. and total  $\text{NH}_3$ .

J. L. WILEY.

**Operating a water gas set without a relief holder in parallel with by-product coke ovens.** A. H. HARRIS, JR. *Am. Gas Eng. J.* 110, 185-8(1919).—Owing to the difficulty of maintaining a city gas supply with sole reliance upon by-product ovens at the plant of the Coal Products Manuf. Co., Joliet, Ill., it became necessary to instal an auxiliary water gas set of the latest standard design of the United Gas Improvement Co., with a capacity of 3.5 million cu. ft. Some trouble was experienced at first in operating due to the inability of the purifiers to handle the increased amt. of gas without

high back pressure, but after some manipulation of the exhausters and some minor changes in the cooler and saturator, a normal operation was obtained. Accurate results are not to be expected, but av. operating economies are suggested. J. L. W.

**Valuation of crude benzenes and a useful separating device.** KENNETH NORTON. *Gas World* 69, 331(1918).—An app. to be used in place of a sepg. funnel in examg. benzene and naphtha is described. It consists of a Winchester qt. bottle fitted with a 3-hole rubber stopper through which passes (1) a narrow vent tube drawn out to a jet at one end, and long enough to reach to the bottom of the bottle, the other end being bent at right angles and temporarily closed with a piece of rubber tubing and glass rod; (2) a short piece of glass tubing passing only half way through the stopper and serving as an outlet, it being ground off obliquely at its lower end in order that it may drain quickly; (3) a glass rod tapered at the end and bent in hook shape and capable of sliding up and down in the stopper so that its tapered end may enter and close the hole above the outlet tube when required, thus acting as a stopper. In performing a test, the benzene or naphtha is well mixed with the caustic or acid, the glass stopper replaced by the rubber app., and the bottle inverted and placed on a tripod for the contents to sep. When the contents have sufficiently sepd., the plug is removed from the bent tube, the valve rod is lifted and the lower layer of liquid allowed to run out. A clean sepn. is readily obtained without any waste. Quick and accurate manipulation is insured. J. L. WILEY.

**Estimation of benzene in gas.** EMILE DE SAINTE-CLAIRE-DEVILLE. *Paris Gas Co. Gas World* 70, 18(1919); *Gas J.* 145, 272-3(1919).—The process consists in freezing out the benzene in the gas with the aid of liquid CO<sub>2</sub>. Some CO<sub>2</sub> snow is inserted into the interior of a Dewar flask, and sufficient acetone is added to make a thick paste. This paste will have a temp. of -81°. Into it is thrust the refrigerating tube, through which the condensate is collected. The gas is passed at the rate of about 50 l. per hr. The temp. in the flask remains below -72° for at least 5 hrs., but usually 3 hrs. are sufficient to obtain enough condensate to give a good measurement by vol. The tube is withdrawn from the flask and allowed to assume the temp. of the laboratory, any excess of gas being allowed to escape, and the vol. of the condensate is read off. Finally the condensate is weighed and the wt. per cu. m. of gas, corrected, is calcd. Besides the frozen benzene, there is also a small amt. of liquid in the tube which gives an indication as to the amt. of toluene in the gas. The general results show that the amt. of benzene produced by the distn. of coal of av. quality is about 1.2% of the wt. of the coal and that 95% of this remains in the gas, 5% only in the tar. J. L. WILEY.

**Method of increasing the efficiency of pot stills for benzene recovery.** J. PARKER. *Gas World* 70, No. 1802 (Coking and By-products Sec.), 12 (1919).—The disadvantages of direct-fired pot stills over steam plants are: (1) failure completely to strip the wash oil of the absorbed benzene even at excessively high working temps.; (2) premature sluggishness of the wash oil owing to local overheating; (3) constant attention required by the operator; (4) danger of fire. B. overcomes the disadvantage of poor stripping by introducing a simple column, packed with earthenware rings, between the pot still and the heat exchangers and running the heated oil therethrough, the benzene being effectively removed by means of live steam, the vapors passing off through the main pipe to the condenser along with the vapors from the pot still. The following results are obtained: (1) the yield of benzene is more than doubled; with the pot still 1 to 1.5 gal. was recovered; (2) the quality is improved from 50-55% at 120° to 65-70° at 120°; (3) due to the lower temp. of distn., 125-130° against 160° and upwards, the wash oil has a longer life. J. L. WILEY.

**Toluene recovery operations in greater New York.** W. J. MCGURTY. *Gas Age* 43, 175-80(1919).—The process used in the plants designed and built for the U. S.

Ordnance Dept. by the Bartlett Hayward Co. is described. Altogether 9 toluene plants were built and operated with a total production for the various periods of time operated of 3,703,826 gals. light oil, 1,525,835 gals. benzene and 975,476 gals. toluene. The total av. purity of the toluene shipments was 82.5% with several of better than 90% while individual plant av. production was over 86%. A description of the operation is of interest on account of its novelty, simplicity and economy. The crude gas prior to entering the purifiers passed through 2 scrubbers filled with wooden grids and in series, designed to allow for a certain gas velocity and time of contact between the wash oil and gas. The ascending gas in No. 1 scrubber was washed with partly benzolized oil which had been used in No. 2 scrubber to secure complete removal of the light oil vapors. The wash oil was pumped through spray nozzles in the top of the app. at a specified rate in gals. per M cu. ft. of gas treated. The oil used was "straw oil." By the use of thermometers in the gas and oil piping it was possible to supply the wash oil at a temp. minimizing the condensation of water vapor from the gas and the efficiency loss due to consequent emulsification of the oil. The outgoing gas passed through a catch scrubber, which not only arrested any entrained oil particles but served also as a mixing chamber for the enriching vapors. The benzolized oil leaving the first scrubber was pumped to a tank under the roof of the still building where foreign matter picked up in circulation was collected. In the app. through which the oil successively flowed, increased temps. were secured through heat absorption from the light oil vapors, then in the oil to oil heat exchanger, thus effecting economies in the steam required to heat the oil. The first steam heater was heated by exhaust steam, the second by high pressure steam in order to provide the necessary oil temp. for the stripping operation. This temp., 115-135°, depended on the time element in the stripping still, requiring increased temps. with increased rates of oil flow. In the cast-iron column still the oil descending from section to section gave up its light oil vapors to an ascending vol. of live steam, which, in passing through the hooded ports, was forced to bubble through the oil, sealing the hoods, the resultant scrubbing action effecting the removal of the desired vapors. The amt. of low pressure steam supplied the latter app. was controlled by a thermostat, which by maintaining a constant temp. in the existing vapors insured further economy in steam. The debenzolized oil leaving the stripping still passed through the oil to oil heat exchanger, then through a tubular fresh water cooler to the decanter, which not only sepd. the water but also collected the sludge and resinous matter in the oil. From the decanter the oil was pumped through refrigerating coils and then returned to the scrubber pump for recirculation. The light oil vapors were conveyed from the stripping still to the bottom of the wash still, the dephlegmating action of which condensed the heavier vapors with the formation of "secondary oil," allowing the lighter or "primary oil" vapors to proceed to the condensers. This method of splitting the vapors made a speedier and more easily controlled fractionation possible. The "primary oil" vapors, after a heat transfer in the first condenser, were cooled with water in the second tubular condenser, passing from there to the decanter. This app., divided into 2 chambers by means of a partition plate, also sepd. the water from the "secondary oil," and each oil overflowed an internal skimmer and passed through condensation meters into their resp. receivers, from which they were removed to storage. The vapors arising from the decanters, distillers, etc., were passed through miniature scrubbers and the condensed oil returned to the decanter. The non-condensable olefin vapors were piped to a small blower for return to the scrubbed gas. These operations formed a continuous cycle, the hourly thermometer readings indicating whether the desired operating conditions were being maintained, and oil meters enabled the operator to check any changes in the rate of oil flow necessary to secure sufficient recovery results from the varying vols. of gas produced during periods of high and low consumption. The final operation, fractions-

tion of recovered oil, was conducted intermittently. Light oil, in charges of 6,500 gals., was pumped into the steel tank-still, provided with a steam-heating element, a superimposed rectifying column and a dephlegmator. The vapors ascending the rectifying column entered each section through a no. of openings, each covered with a cast-iron bell, the perforated edges of which were sealed in oil. The bubbling action produced a result similar to stripping, the lighter vapors passing to the dephlegmator, where selective condensation permitted the desired vapors to proceed to the condenser, while the heavier condensates returned to the column for further treatment. This operation was conducted by means of a recording thermometer on the outlet vapors, the frequent b. p. tests of the condensate being indicative of the progress of distn. as well as to the proper disposition of the products in the storage system. These tests assured also that all the toluene recovered was available for refining and nitrating. The benzene produced was prepared with a dry point of  $85^{\circ}$ .  
J. L. WILEY.

Back-creeping in the burning of gaseous explosive mixtures. ANON. *Gas World* 70, 22-3(1919).—A furnace has been devised which is said to do away with back-creeping of combustion in the gas mixt. discharge nozzle, even with a comparatively low flow velocity. This is accomplished by forming the nozzle of some material of high thermal cond., such as cast iron, and of sufficient cross-section so that all parts shall have the required heat-conducting capacity for carrying away all heat reaching such part. In addition it is set in the furnace wall and protected by suitable refractory cement in such a way that it is shielded from direct access of the furnace heat. For taking from the nozzle the heat conducted from its exposed portions backward through its body and releasing it into the outer air, the nozzle is provided with heat dissipating fins. Such construction has been found entirely satisfactory under various conditions of operation, and makes the provision of special means, such as a circulating fluid, for carrying away the heat from the nozzle wholly unnecessary.

J. L. WILEY.

Acidity of sulfate of ammonia. P. C. GARDINER. *Gas J.* 145, 65(1919).—In order to det. in what way acid is held by  $(\text{NH}_4)_2\text{SO}_4$  samples A, B and C were taken and allowed to drain for periods of time which varied from mins. in the case of A to weeks in the case of C. Analyses showed a % of acid by wt. for A of 1.442, B 0.388, and C 0.165. The reduction in the acidity after long draining indicates that the bulk of it is on the surface of the crystals, and confirmatory washings with equal amts. of neutral water show practically all the acidity to be eliminated by the first washings. Since only the merest trace was found in the 4th and 5th washings, it is concluded that no acidity exists in the interior of the crystal itself.

J. L. WILEY.

Acidity of sulfate of ammonia. JOHN T. SHERARD. *Gas J.* 145, 115(1919).—S. criticizes the work of Gardiner (cf. preceding abstr.) in that such washings of sulfate crystals partially dissolves them and causes loss. S. mentions but does not describe a modification of the ordinary method of sulfate manuf., which he has patented, whereby perfectly neutral salt is obtained at no extra cost. In order to show the behavior of free acid in sulfate when exposed to the air, as regards its effect in preventing the drying of the salt and promoting the absorption of moisture from the air, some sulfate containing 3.5% moisture and 0.5% free acid was exposed to the air for periods ranging from 20 to 260 hrs. At the end of the test there was found 0.27% of moisture, a total loss of 3.23%.

J. L. WILEY.

New Coppée coal washing and coking plant at Port Talbot. ANON. *Gas World* 70, No. 1798 (Coking and By-products Section), 18-20(1919).—The installation consists of: (1) a coal treating plant composed of a coal washery having a capacity of 120 tons of raw coal per hr., together with coal crushing and storage plant; (2) coking plant, consisting of 2 batteries, 120 ovens of the vertical flued regenerative type, capable of

carbonizing per week 5800 tons of washed coal, containing 20-25% volatile matter; (3) by-product plant for recovery of tar,  $\text{NH}_3$ , benzene, and for production of  $(\text{NH}_4)_2\text{SO}_4$  by the "continuous wet process," and rectification of crude benzene for com. 90's, 50's and solvent naphtha. In addition there are provided the necessary boilers arranged for hand-firing, where the slurry from the washers will be burned, a gas holder of 700,000 cu. ft. capacity and a water cooling tower with pumps. J. L. WILEY.

**Centrifugal fans and their application to gas engineering practice.** FRANK S. TOWNEND. *Gas J.* 145, 116-9 (1919); *Gas World* 70, 41-2 (1919).—The paper presents an elementary theory of the fan; a description of the radial flow and the mixed flow type; a discussion of fan efficiency, methods of driving, and their regulation; and a description of concrete examples of the latest practice in the application of fan plants. As a gas engineering device, the centrifugal fan, for large vols. against fairly high heads, is the most compact and efficient of mechanical gas propellers. It is reliable, with a low repair bill. Its high speed enables it to be direct-coupled to the most efficient power units—the steam turbine and the electric motor. Its chief disadvantage is that it will not take overload to the extent that a positive blower will; and its efficiency does not remain at the max. over a very wide range of discharges. J. L. WILEY.

**Fuel briquets.** C. E. HIRE. U. S. 1,290,992, Jan. 14. Coal is formed into briquets with a binder produced by mixing starch 0.5% with  $\text{H}_2\text{O}$  6%, heating and stirring to form a paste of bursted starch granules and then mixing and emulsifying with 1% of petroleum residuum (the proportions being based on the wt. of coal).

**Recovering nitrogen from fuel in gas manufacture.** A. RIEDEL. Dan. 23456, Sep. 2, 1918. Coal, steam and chlorides react in the fire zone to produce  $\text{NH}_4\text{Cl}$ .

**Extracting ammonia from gases.** E. L. PRASE. Brit. 121,754, June 22, 1917.  $\text{NH}_3$  is extd. from hot gases, *e. g.*, gases passing from furnaces or gas producers, by a soln. of a salt, such as  $\text{CaCl}_2$  or  $\text{ZnCl}_2$ , possessing the property of forming a double compd. with  $\text{NH}_3$ , which is delivered as a shower or spray by one or more distributing devices provided with spraying nozzles into a vessel through which the gases are caused to rise. The construction and operation of a suitable app. are specified.

**Oil gas.** HOLLANDSCHE RESIDUUGAS MAATSCHAPPIJ. Holl. 2,655, Oct. 15, 1918. A pair of generators are used, in which oil gas and water gas are produced alternately. Liquid hydrocarbons are used as the initial materials. The water gas formed in one of the generators is conducted to the other generator in which the oil gas was produced, in order that the residue therein may be reconverted into satd. hydrocarbons by hydrogenation. The operation of each generator is then changed.

**Distilling tar, etc.** J. W. WEXWOOD. Brit. 121,804, Jan. 2, 1918. Tar and like liquids are dehydrated and distd. by passing through a preheating tank, a still heated by high-pressure hot-water tubes, and a final sepg. vessel into which the heated tar is admitted in spray or films by means of a pipe, and which is heated by high-pressure hot-water tubes on part of which the tar is caused to impinge. The hot water circulates through a heater arranged in a furnace, from which the products of combustion pass by a flue to heat the still and a sepg. vessel. In treating tar, the contents of the still are raised to about 230°.

**Coking.** C. W. SIMPSON and L. MOORHOUSE. Brit. 121,854, Feb. 19, 1918. Coal, shale, peat, etc., are carbonized in a retort which is heated electrically so that the temp. may be easily controlled. The current is transmitted through the charge by means of electrodes embedded in the lining of the retort or oven and in direct contact with the charge. Cf. 20,115, 1910, 13,951, 1914.

## 22. PETROLEUM, ASPHALT AND WOOD PRODUCTS.

F. M. ROGERS.

**Testing natural gas for gasoline content.** G. G. OBERFELL, S. D. SHINKLE and S. B. MESERVE. *J. Ind. Eng. Chem.* 11, 197-200(1919).—An app. and a method are described for removing gasoline from natural gas by means of charcoal or other adsorbents, with subsequent removal and collection of the gasoline by distn. Both lean and rich gases can be thus examd. The adsorbent, containing the gasoline, is introduced into a flask containing straw oil or glycerol, for distn., the latter being preferable. Both the glycerol and adsorbent can be recovered for use. The results check satisfactorily with those obtained by oil absorption methods. W. F. FARAGHER.

**Present status of refinery practice.** E. W. DEAN. *Oil & Gas J.* 17, No. 38, 52-3(1919).—The output of gasoline may be increased by universal adoption of higher end-point, use of more efficient refining methods and wider use of cracking processes. High-test gasoline now marketed has an end-point of approx. 175°. Usual grades fall between 200 and 230°. Universal adoption of the last temp. would increase the total yield 15 to 20%. Efficiency of fractionation in refineries varies from 75 to 95%. If all could approach the latter figure it would mean an increase of gasoline yield of perhaps 10%. Burton's cracking process is the only one in successful use to-day and it has limitations. Refining losses are about 4%. By use of scrubbers and other recovery app. this loss should be cut to 2%. R. R. MATTHEW.

**Paraffin wax and its manufacture.** A. CAMPBELL and W. J. WILSON. *Engineering* 107, 247-8(1919).—A review. F. W. SMITHER.

**Lubrication (HARDY) 2.** Chemical properties of Utah hydrocarbons (BARDWELL, *et al.*) 8.

**Cracking hydrocarbons.** W. F. RITTMAN and M. C. WHITAKER. Dan. 23,464, Sept. 2, 1918. Hydrocarbons are suddenly and continuously vaporized and subjected to a dissociating temp. during downward flow through a series of columns in which a pressure of at least 4.25 atm. is maintained.

**Cracking hydrocarbons.** C. WHITE. Holl. 2,661, Oct. 15, 1918. Oil or residue is conducted in the liquid state, without the addition of steam, into unslaked lime heated in a retort to 400-650°.

**Apparatus for cracking hydrocarbons.** J. W. COAST, JR. U. S. 1,291,414, Jan. 14. The pat. relates especially to coke-traps connected with cylindrical pressure stills for cracking petroleum oils.

**Treating crude acid resins with solvents.** L. SINGER. Norw. 29,034, Aug. 26, 1918. Crude resin, produced by treating mineral or other hydrocarbons with H<sub>2</sub>SO<sub>4</sub>, is treated, immediately after being sepd. from the mixing app., by kneading and washing with alcs., acetones, or chlorinated hydrocarbons at a suitable temp. and in sufficient quantities to dissolve entrained oils. Entrained hydrocarbons, and adhering H<sub>2</sub>SO<sub>4</sub>, are then removed, the latter being tapped off. The mass is then treated, in one or more operations, with a suitable solvent to sep. it from the remaining H<sub>2</sub>SO<sub>4</sub> and coal-like or coke-like substances. Cf. C. A. 12, 93.

### 23. CELLULOSE AND PAPER.

A. D. LITTLE.

**Pulpwood consumption and wood-pulp production in 1917.** F. H. SMITH. U. S. Dept. Agr., *Bull.* 758, 19(1919); cf. C. A. 12, 1833.—A total consumption in 1917 of 5,480,075 cords of pulpwood was reported by 241 establishments, an increase of 5% over the consumption in 1916. The imported spruce and aspen composed 14% of the quantity used. The production of wood pulp totaled 3,509,939 tons, an increase of 2% over 1916. Tabular material is given showing the consumption of pulpwood by each kind of wood used, consumption by species and states, consumption by processes of manuf., and range of prices. Maine is the greatest pulp-producing state, followed by New York, Wisconsin, New Hampshire and Pennsylvania in the order given.

J. J. SKINNER.

**Celluloid manufacture.** E. W. MANTR. *Elec. J.* 16, 94-5(1919).—Description of elec. machinery used in the process of celluloid manuf. C. G. F.

**Cottons of different degrees of purification** (HALLER) 25. Coating wooden receptacles with waste sulfite liquor constituents (U. S. pat. 1,291,696) 1.

**Paper pulp.** K. BRAMSON (NÉE ADELER). *Brit.* 121,847, Feb. 7, 1918. Paper pulp is made from dead leaves. The blades or laminae may be sepd. from the ribs or stalks by known crushers or breakers and used as fuel, or the whole of the leaves may be used. For paste-board, the material may be heated with H<sub>2</sub>O with or without using pressure. For paper, 5-10% soda lye may be used under pressure. An app. for sepg. the blades or laminae from the ribs or stalks consists of a perforated spherical body rotating within a casing and provided with balls of cast Fe or granite. These first remove the substance of the laminae, which passes through the perforations, and then break up the ribs prior to treatment with liquid. Cf. 1, 853, 1871, 2,168, 1871, 4,259, 1882, and 18,572, 1892.

### 24. EXPLOSIVES AND EXPLOSIONS.

C. E. MUNROE.

**Optic atrophy and multiplex peripheral neuritis developed in the manufacture of explosives (dinitrotoluene).** A. S. HAMILTON AND C. E. NIXON. *J. Am. Med. Assoc.* 70, 2004-6(1918). E. J. C.

**Explosive.** J. D. THOMPSON. U. S. 1,291,258, Jan. 14. A high explosive suitable for use in blasting is formed of KClO<sub>3</sub> 73, randanite (decayed feldspar) 7, wood pulp 3, "liquid binitrotoluol" 15, trinitrotoluene 2, sol. nitrocellulose 0.125, and pulped insol. nitrocellulose 0.125 parts.

### 25. DYES AND TEXTILE CHEMISTRY.

L. A. OLNEY.

**The future development of the dyestuff industry.** L. W. ALWYN-SCHMIDT. *Color Trade J.* 4, 51-3(1919).—The dyestuff industry in the U. S. is firmly established on the road that must lead towards perfection. The character of the foreign market

and the quality of the product produced will be leading factors in the development of the industry. Makers should conc. on the most promising lines, and leave future expansion of the export business to a time when they can make additional dyes of a competitive quality. America is at a disadvantage on costs, but present conditions abroad will tend to equalize manufacturing costs. The world's business outlook is good, and this will be reflected strongly in the color industry. L. A. OLNEY.

**Dyestuffs and the world at large.** PAUL NOBBE. *Color Trade J.* 4, 58-9(1919).—The dyestuff industry more than any other will bring the U. S. face to face with the remotest corners of the earth. Cf. *C. A.* 12, 2443. L. A. OLNEY.

**The sulfur dyestuffs.** J. F. SPRINGER. *Color Trade J.* 4, 54-7(1919).—A discussion of history and compn., with a list of important S colors, including the fundamental materials from which they are made, the name of the manufacturer and patent nos. The method of mfg. several S colors is given. L. A. OLNEY.

**Sulfur dyes for fast printing.** E. GREENHALGH. *Text. Colorist* 41, 39-40(1919).—In the new era of calico printing, the loose color is being displaced by the fast color. Of the latter the S dyestuffs contain practically every requisite shade but red. One of the faults of the present day S colors is the presence of a certain amt. of free sulfide in the paste which in printing attacks the Cu rollers, partially effacing the engraving. Dyes are being improved to avoid this difficulty. An example of the glucose-alkali process is given in the following recipe: Thickening: dextrin 300 parts by wt., corn starch 50, water 150. Color paste: sulfur black paste 100, glucose (40%) 200, NaOH (76° Tw.) 100, thickening 600. Allow to stand with repeated stirring till dissolved and wholly reduced. Print dry and steam in the rapid ager for 2-3 min. at 100-101°. Hang in moist atmosphere 1 hr., then oxidize with one-eighth % bichrome and 1% H<sub>2</sub>SO<sub>4</sub>. Soap 10 min. at the boil. Brighter or fuller shades are obtained by the following modification of this recipe: Thickening: dextrin 300, corn starch 50, Na<sub>2</sub>CO<sub>3</sub> 50, water 200, heat to 71 and cool. Color paste: sulfur black 100, water 100, glycerol 100, thickening 600, formosol (50% soln.) 100. The color is printed, dried and aged 4 to 5 min. at 102-103°, then oxidized as in the glucose-alkali process. Free sulfide may be removed from S colors by washing out with hot water; by boiling the color with Na or K sulfite in the presence of thiosulfate, then acidifying with HCl or H<sub>2</sub>SO<sub>4</sub>, filtering and washing; or by oxidizing the sulfide with H<sub>2</sub>O<sub>2</sub> or Na<sub>2</sub>O<sub>2</sub>. Dyes are tested for sulfide by dissolving in NaOH and placing on clean Cu foil 1 hr.; after washing in boiling H<sub>2</sub>O a black stain shows sulfide. The following recipe gives good results with S colors, such as blues, greens, browns, purples and khakies containing up to 3% free sulfide: Sulfur blue 60, NaOH 20, hydrosulfite 15, water 85, glycerol 100, thickening 600. Heat to 70-80° till dissolved, cool and add formosol (50%) 100, K<sub>2</sub>SO<sub>4</sub> (90° Tw.) 20. Print, age, etc., as for sulfur black printing. L. W. RIGGS.

**Report of Committee D-13 on textile materials.** *Proc. Am. Soc. Testing Materials* 18, Pt. I, 357-79(1918).—A review of the transactions and discussions at the meetings of this committee is given. In Appendix I are the regulations governing this committee which are supplementary to the "Regulations governing Standing Committees." Appendix II consists of a table of corrected tensile strengths of fabric and yarn at moisture regains ranging from 3, and increasing by 0.25 up to 6.5% of the dry wt. Appendix III contains the report of a sub-committee on testing machines. These machines may be placed in two classes: those with constant increment of load, and those with constant increment of stretch. Machines of each class are described and illustrated, also a new machine which is being designed and constructed at the Bureau of Standards. Appendix IV contains a paper by C. E. Swett on the identification of manila fiber (cf. *C. A.* 12, 998). Appendix V (cf. following abstract). L. W. RIGGS

**Effect of moisture on the tensile strength of aircraft fabrics.** G. B. HAVEN. *Proc. Am. Soc. Testing Materials* 18, 380-98(1918).—"In order to apply and enforce specifications for mechanical fabrics, it is necessary to test them with precision and to achieve results which can be interpreted intelligently and accurately. Three methods have been proposed for use in testing textiles, *vis.*, bone dry; under standard atm. conditions at full regain; under any prevailing atm. condition with the result corrected for the actual moisture present at the time of the test." The last method proved to be the best, and all apparent strengths were corrected for moisture to a common basis of 6.5% regain. The fabrics tested were cotton for wings, linen for wings, rubberized for kites, balloons and dirigibles, woven tire and cord tire. These fabrics are described in detail also the app. used, rooms, taking of specimens and making of tests. The results are shown in 5 charts of curves. The summary states that heavy fabrics of cotton, such as tire duck, were found to gain about 7% of the dry strength for each added % of moisture and the same figures held for wing linen. Light cotton fabrics gained about 3% for each added % of moisture. Balloon fabric, a rubberized plied cloth exhibited the same general increase in strength. Cord fabric for tires followed practically the laws of woven fabric for the same purpose. L. W. RIGGS.

**Some effects of moist and dry heat on wool.** A. WOODMANSEY. *J. Soc. Dyers Colourists* 34, 227-30(1918).—The material used was an undyed cross-bred worsted serge, extd. with petroleum ether, well washed with warm distd. water and air-dried. Hygroscopic moisture may be considered as completely removed if the material is maintained at 100° for 40 min., provided there is sufficient ventilation. At higher temps. the elimination of moisture is more rapid, and when the temp. is raised considerably above the b. p. of water, *e. g.*, 150°, a gradual reduction in the wt. of the wool is noticed, owing to the evolution of matter other than water. Variation in hygroscopic moisture affects textile strength, which increases on drying and diminishes on dampening. The elongation before rupture increases upon dampening. Prolonged boiling of wool with water produced partial soln. of wool substance, with liberation of H<sub>2</sub>S and NH<sub>3</sub>. Wool simply dampened with H<sub>2</sub>O regains its original strength upon drying, but wool which had been boiled with H<sub>2</sub>O never regains its entire strength. Dry heat is not nearly so destructive of wool as wet heat. Wool under pressure with water at 130° is completely disintegrated, but dry wool at 200° is weakened less than 7%. Time is an important element in the effect of dry heat. Wool must be heated many hours at 100° to produce a scorched appearance. When temp. is gradually raised the first sign of darkening is visible at 145° and the color continues to deepen to 235°, when the material begins to char and fuse. When heated 3 hrs. at 150° the scorched wool still shows the scale markings but the surface is covered with long striations. At 200° for the same length of time the scale markings are faintly visible but upon disturbing the cover glass the fibers break into short rod-like pieces. Wool heated to 175° for 3.5 hrs. does not re-absorb the normal amt. of moisture, and its absorption power for H<sub>2</sub>SO<sub>4</sub> is also diminished. On heating in a current of air, NH<sub>3</sub> is evolved and this is increased if in moist condition. Heated wool becomes acid, partly on account of oxidation of S to H<sub>2</sub>SO<sub>4</sub>, and partly on account of loss of ammonia. As a protein complex, wool is held to consist of a combination of amino acids linked with the characteristic grouping—CO—NH—(a). The possibility of splitting up at (a) by heat is apparent; the resulting compd. would be an amide or a compound favoring the formation of an amino group. The amt. of NH<sub>3</sub> liberated from wool by heating much above 100° rapidly increases but later on diminishes. By boiling with water wool which had been heated varying lengths of time hydrolysis of the amino groups formed takes place with the formation of NH<sub>3</sub>. Heated wool bears a comparison to faded wool in that it is more sol. in alk. soln. and also has a greater soly. in distd. water. From a neutral dry bath scorched

wool takes up more of an acid dye than unheated wool, presumably on account of its acid character, but from an acid dye bath there is but little difference between the two. With basic dyes the heated wool gives a duller and redder shade. The changes which take place on heating wool are gradual. No critical temp. has been discovered. In all cases time and temp. are dependent variables.

L. A. OLNEY.

Further investigations on constituents of raw cotton. EDMUND KNECHT AND WILLIAM HALL. *J. Soc. Dyers Colourists* 34, 220-7 (1918).—In a previous communication (*C. A.* 6, 935) one of the authors pointed out that Schunck had only accounted for somewhat less than 0.5% of the impurities or substances other than cellulose contained in unbleached cotton yarn. Schunck boiled the cotton yarn in a kier with soda ash, and acidulated the kier liquor with  $H_2SO_4$  and from the ppt. he isolated (1) cotton wax, (2) margaric acid, (3) a coloring matter readily sol. in alc., (4) a coloring matter sparingly sol. in alc., (5) pectic acid, (6) albuminous matter. Since the amt. of impurities in raw cotton was known to be at least 10 times greater than that accounted for by Schunck, and it was considered that prolonged boiling with alkali might bring about drastic changes in these impurities, the authors decided to use as far as possible purely mechanical solvents, this being done in a Soxhlet extractor with benzene, alc., water, dil.  $NH_4OH$  and dil.  $HCOOH$  and finally with 2° Tw.  $HCl$  in a beaker. Previous expts. were repeated on larger quantities of 2-ply 60 American and Egyptian cotton using large copper Soxhlet app. The results previously recorded were confirmed except for slight quantitative differences. The benzene ext. yielded 0.407% (American) and 0.444% (Egyptian) or crude wax. This was sepd. into cotton wax (A) sol. in petroleum ether, and cotton wax (B) insol. in petroleum ether. Test of tensile strength showed that removal of wax increased strength and diminished the elasticity of the yarn. The alc. ext., 0.533% for American and 0.744% for Egyptian yarn, consisted of an amorphous brown hygroscopic substance, reducing Fehling soln., containing a high percentage of mineral matter, chiefly  $K_2O$ ,  $Na_2O$ ,  $MgO$ ,  $SO_3$ ,  $CO$  and  $P_2O_5$ . The aq. ext., 1.656% for American and 1.509% for Egyptian, similar in appearance to the alc. ext, did not reduce Fehling soln. so readily, and like the alc. ext., was faintly acid to litmus. The  $NH_4OH$  ext., made in earthenware jars, yielded 0.425% from American and 0.5% from Egyptian. The  $HCOOH$  ext., 0.65% American, and 0.405% Egyptian. The  $HCl$  ext., also made in earthenware jars, gave for American 0.656% and for Egyptian 0.54%. The total ext. for American was 4.327%; for Egyptian, 4.124%. The original cotton contains 0.204% N in American, and 0.262% in Egyptian; after the extns. the percentages were, resp., as follows: Benzene 0.189-0.240, alc. 0.184-0.226, water 0.175-0.218,  $NH_4OH$  0.175-0.218,  $HCO_2H$  0.168-0.211,  $HCl$  0.138-0.175 and finally after a 2° Tw. bleaching powder treatment 0.022-0.037, thus indicating that mechanical treatment alone only accounted for 14.1 and 16.7%, resp., and the chem. treatments by  $HCl$  and bleaching powder removes 72.3% and 71.3% of the nitrogen present in the original yarn. By using 4° Tw. caustic and boiling for 8 hrs. it was possible to remove most of the N in one operation. Boiling with lime was far less effective in this respect. The mineral constituents of the yarn were reduced from 0.931 American and 1.17% Egyptian to 0.076% American and 0.076% Egyptian. With the object of examg. the substances removed from cotton in the various operations of bleaching, 100 lbs. of soft twist Egyptian yarn were subjected to the following treatment: (1) Lime boil, (2) sour  $HCl$ , (3)  $NaOH$  boil, (4) sour  $HCl$ , (5) chemic, (6) sour  $HCl$ . The ash content of cotton was reduced from 0.89% to 0.15%. The N content after operation (1) was 54%, after (2) 40.5%, after (3) 27.1%, after (4) 36.8%, after (5) 6.7%, after (6) 5.8%. Only the first 3 exts. were examd. Lime ext.: The dry ext. contained 3.7% N but did not give any protein reaction; when treated with alc. it gave a gelatinous ppt., which appeared to coincide with the pectic acid obtained by

Schunck. The first HCl ext. gave a waxy, dirty white substance of a low m. p. which apparently consisted mainly of stearic acid, and by extn. with benzene a small amt. of a substance of higher m. p. was obtained corresponding to cotton wax. Caustic soda ext.: The substance pptd. from NaOH ext. gave 3.46% N and seemed to consist mainly of brown coloring matter. The moisture in the yarn averaged 7.36% before, and 6.14% after bleaching, thus indicating that the moisture content of unbleached yarn is not wholly dependent on cellulose but partly on hygroscopic accompanying substances.

L. A. OLNEY.

Cotton cellulose—structure and constitution. C. F. CROSS AND E. J. BEVAN. *J. Soc. Dyers Colourists* 34, 215–20(1918).—Fort (C. A. 12, 2694) deals with the destructive breakdown of cotton under the process of beetling. A sample of powdered cellulose thus produced has been examd. by C. and B. The form and extreme dimensions of the particles are similar to those of starch granules. They are non-reactive toward polarized light in comparison with the original cotton fibers. The elementary analysis calcd. on the ash free, dry product corresponds to the formula  $C_6H_{10}O_5$ , and the hygroscopic moisture 5–6%. Treatment with 17.5% NaOH soln. gave indication of a decided modification giving 44.2%  $\alpha$ -cellulose, 48.6%  $\beta$ -cellulose, and 72%  $\gamma$ -cellulose. Both  $\alpha$ - and  $\beta$ -cellulose showed considerable resistance acetylation, the yield of the two being 122% against 178% of the triacetate in the case of a normal cellulose. The cotton powder is characterized by a particularly low sp. vol. (0.635) or high d. as compared with normal cotton. Since the product in some ways resembled starch, expts. were made on potato starch with the following conclusions: (1) The starches are characterized by vol. changes with temp. similar to those of the celluloses. (2) In the case of starch in the natural air-dried condition there is no break in the expansion curve at the swelling point; on the other hand, a specimen previously dried at 100° showed considerable irregularity through the range of 20–60° with a general increase of vol. to a max. at the swelling point followed by a rapid fall. The reduction of fibrous cotton cellulose to powder appears to be the result of a mechanical shock, but there is no doubt a factor by or through which the mechanical effect is translated into some form of energy which affects the interior equil. of the cellulose complex, degrading it to a relatively rigid form, which then, having lost its structural continuity, breaks up into fragments.

L. A. OLNEY.

Cotton cellulose. C. F. CROSS AND E. J. BEVAN. *J. Soc. Dyers Colourists* 34, 247(1918); cf. preceding abstract.—Of a cotton rope used as a drive in a cool, well ventilated work room free from fumes, 3 different lengths from the same supply became rotten and broke. The rope, 1.5 in. thick, was entirely disintegrated and full, all its length, with dust. A sample of dust and granules from this rope, upon examn., proved to consist for the most part of rounded nodules of hyaline matter (A) with a few fragments of cotton fiber (B). (A) in air-dried state showed 13.26% moisture. Its conversion into dextrose gave results which identified it as cellulose. (B) examined under the microscope showed little structural change, but the ends were sharply fractured. The residual pieces of fiber were very brittle. They were also sol. for the most part in mercerizing soda soln.

L. A. OLNEY.

Defects in finished cotton goods. Sources of imperfections that show in later processes. LOUIS J. MATOS. *Text. World J.* 55, 39–41(1919).—Defects made in the course of bleaching are usually caused by inattention to the details of the work. These details should be constantly under the eye of workmen who feel the responsibility of their jobs. Scorching during singeing may be caused by belts slipping resulting in a decreased speed of the goods over the plate. When the right speed of the goods and a corresponding right temp. of the plate had been detd. by expt. these conditions should be rigidly followed. Partial destruction of the cotton by scorching so alters its compn.

that the goods will not dye evenly with direct dyes. The presence of Mg salts, while improving the feel of the cloth, converts some of the fiber into oxycellulose which does not take the color as readily as unaffected cotton when dyed with direct dyes. Mg compds. should not be used in any part of the process. Incomplete removal of sizes and dressings applied to the yarn before weaving, and the natural residue of fatty and waxy matters in the cotton are responsible for many defects. When the malting is given the requisite time completely to resolve the starch the fabric is in a most satisfactory condition for dyeing. If instead of malting the goods are subjected to a lime boil, the subsequent treatment should remove the lime completely; and for this purpose HCl is recommended for a "sour" instead of the  $H_2SO_4$  which is usually employed. The formation of oxycellulose is the worst common cause of stains on bleached cloth and is usually due to defective circulation of the bleaching liquid. Constant vigilance is the only remedy. Cloth dyed with vegetable colors should be promptly washed and mangled after dyeing. Generally sulfur colors are least affected by defective bowking or chemicking, as the dye appears to have about the same affinity for oxycellulose or unchanged cotton. With sulfur dyes it is very necessary to keep both dye and cloth out of contact with Cu in any form. Sulfur stains are removed by running the cloth through a jig charged with dil.  $Na_2S$  and NaOH. This may remove some of the color and require re dyeing. It is better to prevent the S stains by washing as quickly as possible after dyeing.

L. W. RIGGS.

**Cottons of different degrees of purification; behavior of cotton towards solutions of metallic salts.** R. HALLER. *Chem. Ztg.* 42, 597-9(1918); *J. Soc. Chem. Ind.* 38, No. 3, 70A.—Samples of Indian, American and Egyptian cotton were prepared in different stages of chem. purification, and treated at ordinary temp. for 48 hrs. with solns. of  $Al_2(SO_4)_3$ ,  $Al(AcO)_3$  and  $Pb(AcO)_2$ . The change in the metallic base content of the soln. was detd. as an approx. measure of the adsorption, and the amt. of metallic base fixed by the cotton after washing was detd. by ignition. In some cases with  $Al_2(SO_4)_3$ , and in all cases with  $Al(AcO)_3$ , a negative adsorption was obtained, i. e., the concn of metallic base in soln. was increased instead of decreased by the action of the cotton. With  $Al(AcO)_3$  the negative adsorption was smallest with raw fiber, and became greater as the degree of purification was increased. Cotton which had been boiled with lime gave higher values than that boiled with NaOH. Negative adsorption was most pronounced with Egyptian cotton. With  $Al_2(SO_4)_3$  positive adsorption obtained in all cases with raw cotton, and with lime-boiled cottons. Negative adsorption was shown by samples boiled, resp., with NaOH, lime and soda, and fully bleached.  $Pb(AcO)_2$  in all cases showed a large positive adsorption, increasing with the degree of purification of the cotton. Th: max. adsorption in all cases, both positive and negative, corresponds with the max. degree of purification of the cotton, which is obtained by boiling first with lime, then with NaOH, with a sour after each boil. Treatment with bleach liquor appears to decrease the purity of the cellulose, since it lowers the adsorption values. Adsorption does not necessarily run parallel with the fixation of insol. base in the fiber. With Al salts there was a fixation of alumina, even when negative adsorption values obtained. In the expts. with  $Pb(AcO)_2$  showing a high positive adsorption, a large fixation was observed in the case of the raw cottons, and the appearance suggested that lead oxide had combined with the non-cellulose constituents. After boiling, the fixation of lead oxide became smaller, with increasing purity of the cotton, although the adsorption became more marked.

R. B. ROG.

**Bleaching of colored striped cotton piece goods.** A. C. WALSH. *J. Soc. Dyers Colourists* 35, 35-9(1919).—Two types of colored bleaching are discussed. These are shirtings and so-called "dhootie bleaching" with colored borders. With the latter a specially white ground is not demanded, and colors used are often only of fair quality.

With the former greater fastness is demanded, and a whiter ground. The available colors are indigo, aniline black, alizarin red, and such vat colors as possess the greatest fastness to the bleaching process. Several colors of different fastness may be present in the same cloth, *e. g.*, indanthrene blue and indigo; the former stand a far greater amt. of chemicking than the latter. Before bleaching it is often best to put small pieces through the process, unless the dyes used are specified. Bleaching in the piece always gives a better appearance than bleaching in the yarn before weaving. In the bleaching process the main points to avoid are the reduction of colors in the kier and over-oxidizing in the chemic. It is in the alkaline treatment that reduction of the colors may occur, due partly to presence of org. matters as natural and accidental impurities, or even conversion products of cellulose itself. This reduction results in the marking off of colors. Low-pressure boil in  $\text{Na}_2\text{CO}_3$  free from  $\text{NaOH}$ , for about 4 hrs. Kier boiling may be avoided by running cloth open width through a scouring box, containing  $2^\circ$  to  $3^\circ$  Tw. alkali and then into a kier where liquor is circulated by means of a pump, at a temp. of about  $70^\circ$  for 6 hrs. This process will avert marking off. Starch may be well removed before kier treatment with some malt product. High-pressure kiers should be avoided. Chemicking is usually done in a clear bleaching powder soln.  $1^\circ$  to  $1\frac{1}{2}^\circ$  Tw. for 2-3 hrs., time and strength being dependent upon the quality of the goods and nature of color. Admixture of the chemick with air increases the rapidity of the bleaching and for this reason some colors will not stand the circulation of soln. For even bleaching best results are obtained if chemic is circulated as the goods are being plated into the cistern. The addition of lime water will check bleaching action. Sour consists of  $\frac{1}{2}^\circ$  Tw.  $\text{HCl}$  or  $\text{H}_2\text{SO}_4$  for  $\frac{1}{2}$  hr., which most colors will stand. With those that will not, use anti-chlor, *e. g.*,  $\text{Na}_2\text{S}_2\text{O}_5$ . Washing must be very thorough between the chemick and sour. To secure a more thorough white the whole process is sometimes repeated in less severe form. The final wash must be very thorough and a final soaping is frequently an advantage. L. A. OLNEY.

**Finishing and tensile strength**—tests to show the amount of tendering involved. ANON. *Text. World J.* 55, 37(1919).—The amt. of alteration which woven fabrics undergo during dyeing and finishing depends upon 4 factors, *vis.*, type and quality of raw materials employed; type and structure of warp and filling yarns; the structure and setting of the cloth in the loom; the particular process and degree of treatment in each to which the fabric is subjected during dyeing and finishing. These points have been investigated at the Bradford Technical College and some of the results are exhibited in a chart. It is clearly shown that the processes of crabbing, scouring and permanent finishing are responsible for an appreciable amt. of tendering. L. W. RIGGS.

**Fabrics from nettle and hemp.** ANON. *Text. World J.* 55, 73, 123(1919).—The employment of nettle fibers for fabrics is a revival of olden times when these fibers were largely used for home-spun goods. China still uses the fibers of *Boehmeria nivea*, a species of nettle, for the production of grass cloth, a durable fabric made by hand. It is claimed in this paper that nettle fibers are excellent for coarse cloths where the spinning count is not above 20s, and that it could replace cotton in the manuf. of half-woolen goods such as blankets, hosiery, etc. Successful cultivation of the nettle plant in Staten Island is reported and it is stated that the leaves form a valuable cattle food. Nettle stalks cannot be retted like flax or hemp, but are decorticated by machinery, then boiled under pressure with a suitable solvent to sep. the fibers which may be carded and spun in the regular way. Nettle fibers may be produced in strictly ultimate elements in length from 2 to 6 inches. It is estd. that clean fiber ready for spinning may be produced to sell with a profit at 7 cents per pound. Usually hemp is used for cordage and coarse goods, but with greater care in the treatment of hemp, fibers may be produced similar to the high grades of Egyptian cotton. L. W. RIGGS.

**Soluble antimony compounds—factors which enter into their evaluation.** WESSFORD. *Text. World J.* 55, 43-7 (1919).—Substitutes for tartar emetic are best valued by dye tests performed as follows: Start with the requisite number of 5-g. pieces of cloth of exactly the correct wt., and mordant them all in the same bath of 5% high-grade tannic acid with const. careful stirring. Bring up to the boil during 30 min., boil a few min. and allow to cool slowly with const. stirring. Allow 1.5 to 2 hrs. for the whole operation. Wring the samples with the same pressure directly from the tannic acid soln. without rinsing and spread the samples out alike. The Sb may be applied in 2 ways and both should be used to check each other. A 1% soln. of Sb, from each sample of Sb compd. tested, is made up and placed in its respective dye pot, each pot containing 200 cc. One piece of the tanned cloth is entered into each pot for 30 min., cold. Wash thoroughly and mark the pieces for identification. Finally the pieces are entered all together into 1% methylene blue and dyes as usual in the mill operation with sufficient stirring to get level shades. The strongest Sb salt will give the darkest shade. The 2nd method varies from the first only in the manner of fixing. Using one of the salts as a standard at about 1%, the corresponding strengths of the others are figured to represent equal costs. In these results the darkest shade represents a cost equal to the others, but a better money value. These tests should give a basis on which the product can be tested in the mill. Some of the Sb compds. liberate acids which should be neutralized by adding  $\text{Na}_2\text{CO}_3$  until a faint turbidity appears. Among the most successful of the tartar emetic substitutes are those containing  $\text{SbF}_3$ .

## 27. FATS, FATTY OILS AND SOAPS.

E. SCHERUBEL.

**Wartime vegetable oils.** J. KLIMONT. *Pharm. Post* 51, 561-2 (1918); *Chem. Zentr.* 1918, II, 735.—*Corn oil*,  $d_{20}$  0.917,  $d_{15}$  0.920,  $n_D$  1.4740, acid no. 29.0, sapon. no. 189.7, I no. 119.9; the acid no. of 20 samples ranged from 22.5 to 30.3. The oil can be made tasteless by refining. *Pumpkin-seed oil*,  $d_{20}$  0.9235,  $n_D$  1.4740, acid no. 69.5, sapon. no. 190.5, I no. 120.8. Refining produces a good edible oil. *Walnut oil*,  $d_{15}$  0.9244,  $n_D$  1.4720, acid no. 69.2, sapon. no. 192.7, I no. 133.9. *Hazelnut oil*,  $d_{15}$  0.9165,  $n_D$  1.4690, acid no. 3.7, sapon. no. 192.7, I no. 85.4; the acid no. of different samples 5.5-5.6. This is one of the best of edible oils. *Tobacco-seed oil*,  $d_{15}$  0.9261,  $n_D$  1.4770, acid no. 13.0, sapon. no. 192.9, I no. 136.6; the color is dark green; refining produces a good edible oil. *Raspberry-seed oil*,  $d_{15}$  0.9306,  $n_D$  1.4880, acid no. 47.2, sapon. no. 129.9, I no. 154.7; the color is dark; refining produces a brown edible oil. *Poppy oil*,  $d_{15}$  0.9237,  $n_D$  1.4740, acid no. 32.4, sapon. no. 192.0, I no. 128.1; the color is dark yellow. *Sunflower oil*,  $d_{15}$  0.9235,  $n_D$  1.4760, acid no. 4.8, sapon. no. 188.9, I no. 131.5; the color is light yellow.

C. O. EWING.

**African oil palm, its possibilities in Malaya.** B. J. EATON AND F. G. SPRING. *Agr. Bull. Federated Malay States* 6, 493-512 (1918).—A thorough discussion of this subject is given, including varieties, culture, costs and description of various kinds of machinery used in the industry.

E. SCHERUBEL.

**Rational utilization of dead animals.** FRABOT. *Ann. chim. anal. chim. appl.* 1, 55-65(1919).—The process described is similar in principle to that used in this country which consists in rendering and saving the by-products of grease and fertilizer.

E. SCHERUBEL.

**Coconut products in the Philippines.** W. S. COOKSON. *Agr. Bull. Federated Malay States* 6, 517-20(1918).—This article is a brief survey of the coconut oil industry in the Philippines. The relative efficiencies of the hydraulic press and the Anderson expeller for recovering the oil are discussed. At the present time the latter is being imported more than any other type of oil machinery on account of its simplicity, cheapness and ease of installation and operation. It will recover from 48 to 52% of oil against 55% extd. by means of the hydraulic press.

E. SCHERUBEL.

**The removal of the residual fibers from cotton seed and their value for non-textile purposes.** E. C. DE SEGUNDO. *J. Roy. Soc. Arts* 67, 183-202(1919).—A general review and discussion based on American and British practice. Cf. C. A. 12, 1601.

F. W. SMITHER.

**The cold processes for official soaps (JORDAN) 17. Lubrication (HARDY) 2. Utilization of grape seed in California (SERRE) 12.**

**Hydrogenating unsaturated fats and oils.** J. DEWAR and A. LIEBMANN. *Holl.* 2,658, Oct. 15, 1918. Oils are treated with H in the presence of a catalyzer which is formed on the surface of a carrier. The catalyzer may be formed of (a) oxide or carbonate of Ni or Cu or both, with the hydroxide, oxide, or carbonate of Cu, or (b) hydroxide, oxide or carbonate of Ni or Co with Pd, Pt or Ag, with or without the hydroxide or oxide of Cu. Cf. C. A. 12, 2139.

**Hydrogenating fatty substances.** J. BOYCE. U. S. 1,291,384, Jan. 14. A fatty substance to be hydrogenated mixed with a catalyst, e. g., cottonseed oil and pumice coated with Ni, is treated with H until the desired degree of hydrogenation is effected and the catalyzer is then sepd. from the hydrogenated product in a vessel from which air is excluded to prevent oxidation.

**Cetyl alcohol.** S. AXELRAD and I. HOCHSTADTER. U. S. 1,290,870, Jan. 14. The pat. relates to the obtainment of cetyl alc. by distn. of a Ca soap of spermaceti. Melted spermaceti 15 parts is mixed with about 20 parts of CaO containing about 5% H<sub>2</sub>O and the mixt. is heated and stirred for six hrs. The product is then placed in a still, heated at about 100° until the H<sub>2</sub>O is driven off and then heated to 340° to effect the distn. of cetyl alc., which distils in the form of white fumes, forming oily drops on cooling, which solidify to a white mass resembling paraffin, m. 49.5°. The distn. may be effected *in vacuo* at a lower temp. and the Na, K or Mg soap of spermaceti may be distd. in the same manner. A yield of 40-45% cetyl alc. (based on the wt. of spermaceti) is obtained.

## 28. SUGAR, STARCH AND GUMS.

A. HUGH BRYAN.

**Notes on extraction methods.** L. H. RAYNER. *Louisiana Planter* 62, 157-9(1919).—The latest cane mill design comprizes two crushers of two rolls each, followed by 18 mill rollers. An extn. of 98% is secured, as against 83% obtained by a 9-roller mill. But more maceration water must be used in the longer mill; a large number of spare parts must be carried, or a large machine shop maintained. Electrification does not overcome all the difficulties in balancing the steam consumption of the different departments, where outside fuel must be used in addition to bagasse. Constant extn.

cannot be obtained with any mill. The question arises whether it would not be more economical to secure a 98% extn. by an improved diffusion process, and use a 9-roller mill to press the chips so that they could be used for fuel like mill bagasse.

F. W. ZERBAN.

**A new method of clarification for cane juices in raw sugar factories.** PETREE AND COMPANY. *Louisiana Planter* 62, 140(1919).—This process aims to do away with filter presses in the cane sugar factory by distributing the filter-press mud after special treatment over the bagasse in the mill at a point where the liquid in the bagasse is richer in sugar than the mud.

F. W. ZERBAN.

**The sugar industry in the Island of Guadeloupe,** F. W. I. J. SIDNEY DASH. *Louisiana Planter* 62, 124-6(1919).—A general article on the agricultural side of the industry. An expt. station has recently been erected which will take up soil problems and other investigations.

F. W. ZERBAN.

**The production of beet-sugar in France using French sugar-beet seed.** MENNESSON. *Compt. rend. acad. agr. France* 5, 95-113(1919).—German beets yield 3% more crude sugar than French beets. This is due to (1) the influence of climate and of soil, (2) diminution of sugar content by fertilizers and manures, late sowings, irregularity of plants, etc., (3) bad storage in large moist silos, and (4) losses on weighing. Methods for improvement are suggested.

ALBERT R. MERZ.

**Preparation of soluble starch.** A. LEULIER. *J. pharm. chim.* 18, 291(1918).—Heat a mixt. of starch, 25 g., (of wheat, rice or maize) 95% EtOH 100 g., H<sub>2</sub>SO<sub>4</sub> 5 g., at a reflux condenser to boiling for about 15 min. Filter, wash with cold H<sub>2</sub>O or EtOH until the washings are free from acid, and dry. Sol. starch is pearly white, insol. in cold, very sol. in hot H<sub>2</sub>O. The blue I compd. is sol. in H<sub>2</sub>O. S. WALDBOTT.

#### Fertilizer experiments on sugar cane (CROSS) 15.

ROLPH, G. M.: *Something about Sugar: Its History, Growth, Manufacture and Distribution.* San Francisco: John J. Newbegin. 341 pp. For review see *Expt. Sta. Record* 39, 538(1919).

### 30. RUBBER AND ALLIED SUBSTANCES.

JOHN B. TUTTLE.

**The influence of single tapping and of oblique cuttings on latex and rubber.** O. DE VRIES. *Archief v. d. Rubbercultuur in Nederl.-Indië* 2, 241-55; *Chem. Weekblad* 15, 1392(1918); cf. *C. A.* 13, 386.—It is often stated that the system of tapping by oblique cuttings yields an inferior rubber. After such a cutting the rubber content of the latex drops suddenly from 25% to 21%, and the sp. gr. of the serum increases from 0.9910 to 0.9960. The velocity of vulcanization increases and the viscosity decreases; but these differences are not great enough to have much practical effect. No continuous falling off in quality could be detected.

JULIAN F. SMITH.

**Bacterial changes in latex.** G. STAFFORD WHITBY. *Agr. Bull. Federated Malay States* 6, 513-6(1918).—Kendall has shown (*C. A.* 7, 3605) that in bacterial metabolism, fermentation takes precedence over putrefaction. Whitby questions the statements of Gorter and Swart (*C. A.* 11, 1055) and Eaton (*C. A.* 11, 1055) that the effect of adding sugar is to produce conditions favorable to the formation of fermenting bacteria, and unfavorable to those causing putrefaction. W. states that putrefactive activity

produces an anti-coagulating effect quite apart from that caused by the alkalinity developed.

JOHN B. TUTTLE.

**Keeping (ripening) of coagulum.** O. DE VRIES. *Archief v. d. Rubbercultuur in Nederl.-Indië* 2, 213-40; *Chem. Weekblad* 15, 1391-2(1918).—"Ripening" coagulum gives the rubber greater viscosity and better mechanical properties after vulcanization, but the reported increase of 20% in tensile strength could not be confirmed. Further, the velocity of vulcanization of such coagulum varies greatly, and there is no uniformity of product. The compn. and rubber content of the latex, and extn. of the fresh coagulum with  $H_2O$ , are important factors. Whether the ripening will find com. application is doubtful, in view of the increasing use of artificial accelerators.

JULIAN F. SMITH.

**The tensile strength of rubber-sulfur mixtures.** O. DE VRIES AND H. J. HELLENDOORN. *Archief v. d. Rubbercultuur* 2, 769-91(1918); and *Meded. Centraal Rubberstation*, No. 11, 1-23.—The authors investigate the change in the position of the stress-strain curves and the magnitude of the tensile strength with increase in the period of cure at  $148^\circ$ . With their usual mixt. of 92.5% rubber and 7.5% S, they find that (a) for all the samples of rubber investigated (18) the tensile strength rose to a max., and then both it and the elongation at break diminished continuously, (b) the stress-strain curves came down the paper continuously, (c) in the cases of first latex crepe and smoked sheet, the curve corresponding to the max. tensile strength lay on or near the standard curve, whose position is represented by an elongation of 990% at 1.3 kg./mm<sup>2</sup>, which the authors had previously chosen for their testing, but was lower down on the paper for other varieties of rubber (scrap- and washwater-crepe). In the above expts. the number of separate tensile tests made for each cure was considerable. In 3 cases the total no. of rings tested was 497, 192, 416. The small probable errors in the figures for tensile strength are recorded in the paper. With mixts. containing smaller amts. of S (6, 5, 3%), different phenomena were observed: (1) The tensile strength rose to a max., but the latter was less sharply marked than in the case of the 7.5% mixt. (2) The tensile strength diminished continuously as the period of curing increased beyond that giving the max. tensile strength, but the elongation, after diminishing at first, increased again later. (3) The max. tensile corresponded to the almost complete combination of the S. (4) The stress-strain curves, after coming down the paper, showed a backward movement ("reversion") if the curing was continued sufficiently far beyond the point at which the S was substantially all combined.

G. S. WHITBY.

---

Effect of moisture on the tensile strength of aircraft fabrics (HAVEN) 25.

---

**Reclaiming rubber waste.** J. F. JOHNSTON. U. S. 1,291,535, Jan. 14. Waste rubber containing cotton is subjected to the action of a reclaiming soln. containing 2% NaOH and containing, also, for each 100 lbs. of rubber to be treated, 5 lbs. resin and 15 lbs. of kerosene. The waste is agitated in the soln. at a temp. of about  $160^\circ$ .

**Composition of reclaimed rubber and cotton.** J. F. JOHNSTON. U. S. 1,291,536, Jan. 14. A material suitable for the manuf. of shoe soles and heels is formed of reclaimed rubber mixed with cotton fiber which has been subjected to the action of caustic alkali and which has been sepd. from waste rubber in a reclaiming operation.

**Screw propellers.** E. CARETTA. Brit. 121,589, Oct. 31, 1918. Aircraft propellers are formed from blanks consisting of fibrous material incorporated in vulcanizable rubber molded at a high temp. so as to convert the rubber into ebonite. The blanks may be made up of alternate layers of woven material, preferably canvas, and vulcanizable rubber.

# CHEMICAL ABSTRACTS

Vol. 13.

MAY 10, 1919.

No. 9

## I. APPARATUS.

L. C. JONES.

The limits of separation by fractional distillation. S. F. DUFTON. *J. Soc. Chem. Ind.* 38, 45-67(1919).—A new still-head for fractionating small quantities is described. This still-head was found to give far greater efficiency than that of the Young pear bulb column in common use. The still-head column was made by creating a spiral track in a narrow annulus between a glass tube, 17 mm. internal diam. and an inner tube closed at both ends, 13 mm. external diam., round which was wound a spiral of wire 1 mm. diam., with a pitch of 0.20 mm. When the still-head was in use the wire collected to it itself, as anticipated, the greater part of the descending liquid and became sealed by this liquid to the tubes, causing the ascending vapors to pass along the spiral track, so that, although the annulus was very narrow, the ascending vapor and descending liquid passed each other freely. Later, a still-head was constructed which was 120 cm. long and made of glass quill tubing in sections increasing in diam. downwards. The top section was of such a size that a bicycle spoke, 1.4 mm. diam., round which was wound a spiral wire 0.7 mm. diam., would fit with slight friction; the next section below had wire 1 mm. diam., the third 1.2 mm., and the last 1.4 mm., all wound spirally on similar cores, with increase of pitch from 6 mm. at the top to 12 mm. at the bottom. The graduation is necessary to carry away the increasing vol. of condensed liquid. The limits of sepn. by fractional distn. are discussed briefly.

J. H. YOUNG.

Apparatus for extraction of liquids in towers filled with Raschig's rings. F. RASCHIG. *Z. angew. Chem.* 31, I, 183-5(1918); *J. Soc. Chem. Ind.* 37, 677A.—The introduction of Raschig's rings (Brit. pat. 6,288, of 1914 (*C. A.* 9, 2433) and Ger. pat. 292,622 (*C. A.* 11, 1277)) overcomes certain objections to the application of the counter-current principle to processes in which a liquid is purified by treatment with another liquid immiscible with it. The app. consists of an Fe cylinder, 8 m. high and 60 cm. diam., in which a screen is fixed 1 m. from the base. On this screen rests a column (6 m. in height) of Raschig's rings (25 mm. diam.). An inlet tube (2 m. length and 30 cm. diam.) is fixed in the middle of the cylinder at the top, and serves to admit the heavier liquid, while the lighter liquid is introduced through a long, upright tube which enters the cylinder just below the screen. The heavier liquid sinks ultimately to the bottom of the chamber below the screen, whence it passes out through a long, upright tube, of such a height that the heavier liquid in this tube balances the column of the mixt. in the cylinder. The lighter liquor overflows through an outlet in the side of the cylinder near the top. The runnings are always clear, any emulsion or other deposit settling on the rings, which are cleaned when necessary, by emptying the app. and running in a suitable solvent. This app. may be advantageously applied to the purification of mineral oils by treatment with  $H_2SO_4$ , the recovery of aniline from weak solns. by extn. with benzene, the extn. of AcOH with ether, and of alc. from dil. solns. with benzene.

E. J. C.

Protection against drip water in an extraction apparatus. F. LIEBERT. *Chem. Weekblad* 16, 74(1919).—To keep water that collects on the outside of the condenser

from dripping down into the ext. liquid, cover the lower part of the condenser with a layer of paste made from shredded filter paper and  $\text{CaCO}_3$  with a little  $\text{Ca}(\text{OH})_2$  soln. After hardening, this paste will absorb the drip water. JULIAN F. SMITH.

Device for determining the dropping point (melting point) of fats, waxes, paraffin wax, etc., and especially bitumens. F. DUPRÉ. *Chem. Zig.* 42, 398(1918); *J. Soc. Chem. Ind.* 37, 615A.—A metal cup with a small central opening in the bottom is filled with the bitumen or the like, the latter being first melted if necessary. The cup fits into the lower end of a metal tube surrounding the lower end of a thermometer, the bulb of which is just above the top of the metal cup. The thermometer with attached metal tube and cup is mounted by means of a cork inside a test-tube. This is placed in a beaker of water or  $\text{H}_2\text{SO}_4$ , which is heated at first strongly to within  $10-20^\circ$  of the m. p. and then so that the temp. rises about  $1^\circ$  per min. The results obtained with tallow and paraffin wax agreed well with those obtained by Ubbelohde's app. (*Z. angew. Chem.* 18, 1220-5(1905)), over which the new app. has several advantages, especially for bitumens, etc., of higher m. p. E. J. C.

A new apparatus for determining ammonia. J. ORCEL. *Bull. soc. franc. min.* 41, 53-7(1918).—This is an improvement over the app. of Schloesing. The  $\text{NH}_3$  is liberated by alkali in a round-bottom flask, and passes upward through the leg of a large T-tube, lined with rings of recurved conical points alternating with plates, presenting thus an extensive cooling surface. The cross bar of the T-tube has projecting into it at one end a tube through which cold water circulates; the liquid which condenses on this runs toward the other end, because of a slight inclination, and descends through a long, narrow tube, drawn out from this end of the main T-tube's cross-bar. It then enters the top of a funnel-tube, the bottom of which is enlarged slightly and perforated by a ring of small holes, and dips under the absorbing liquid. Details of manipulation and analytical data are given, showing this method to yield accurate results. E. T. WHERRY.

New Vulcan-Orsat flue gas analyzer. ANON. *Elec. Rev.* 74, 438(1919).—A modification of the Orsat in which a master valve controls all passages and eliminates rubber vent tubes. The face of the valve has a dial insuring the desired communication when turned to the proper mark. Pipets and vent tubes are easily removed for cleaning or re-charging, and the leveling bottle has thumb control which regulates the flow of liquids and gases. The app. is readily transportable and is made in two sizes: one for  $\text{CO}_2$ , O, and CO, and the other for CO only. Repair parts are numbered, making replacement easy. W. H. BOYNTON.

Apparatus for the continuous testing of gases with special reference to acid or alkaline constituents. C. A. KING. *J. Soc. Chem. Ind.* 38, 337.—"A current of gas from the main is caused to pass upwards through a small glass absorption chamber about 7 cm. long and 1.5 cm. diam., provided with projections from the inner wall to effect more efficient contact with a soln. of a suitable indicator, which flows from a U-shaped tube into the upper end of the extn. chamber. The indicator soln. drains away from the lower end of the absorption chamber through a similarly shaped tube in which any change in color of the soln. is noted. The inlet and outlet bends are of such a length that the soln. forms a liquid lute against the pressure of gas in the app."

ERLE M. BILLINGS.

Apparatus for measurement of gases in volumetric analysis. H. FINCKE. *Chem. Zig.* 42, 415(1918); *J. Soc. Chem. Ind.* 37, 608A.—A 200-250 cc. graduated cylinder is closed by a rubber stopper carrying a siphon with arms of equal length, one of which reaches nearly to the bottom of the cylinder and the other nearly to the bottom of a taller and wider cylinder, and a tube bent at an angle of  $45^\circ$  and connected to a reaction

flask contg. a weighed quantity of the sample sufficient to yield about 100–150 cc. of gas. The acid or other reagent is contd. in a flask which is connected to the reaction flask by means of a tube bent at right angles. The graduated cylinder and the siphon are filled with a satd. soln. of NaCl. The flask contg. the reagent is inverted and the latter then flows into the reaction flask, the gas evolved expelling a corresponding vol. of salt soln. from the first into the second graduated cylinder. In this app. the use of rubber tubing and stopcocks is avoided.

E. J. C.

**Automatic ore-pulp sampler.** ANON. *Eng. Mining J.* 107, 412(1919).—The sample cutter is in the form of a narrow vessel with a very narrow and long slot. The cutter is placed under the discharge from a launder, with the slot parallel to the launder; and the whole device is moved across the stream of pulp in a direction at right angles to the length of the launder. The actuating device is a water tippler. A test in which the whole stream of pulp was collected and dried to compare with the sample showed a negligible error of sampling.

W. L. BADGER.

**Thermocouples.** ANON. *Ber. Physik.-Techn. Reichsanstalt* 1917; *Stahl u. Eisen* 38, 1044(1918); *J. Soc. Chem. Ind.* 38, 29A.—From tests with various base-metal thermocouples the following conclusions are drawn: Thermocouples with one element of Fe (constantan-Fe, Ni-Fe) should not be used above 800°. Couples having a free thin Ni wire should not be used for long periods at temps. above 1100° in contact with air, and will in future only be tested up to this temp. by the Reichsanstalt. Couples formed by 3-mm. wires of Ni and Ni-Cr, resp., may, however, be used up to 1200°. Ni-C couples consisting of Ni wire passing through a concentric C tube and thus protected against oxidation may be used for a considerable time at 1200°, and for short periods at 1250°.

E. J. C.

**Furnaces for the production of high temperatures.** A. BIGOT. *Chimie et industrie* 2, 27–36(1919).—The Perrot furnace is a down-draft gas-fired lab. pot furnace. It ordinarily gives about 1200° with illuminating gas. By adding a recuperator the temp. was raised to 1400°. A new furnace was built with  $Al_2O_3$  bricks for the lining, pulverized insulating layers between the refractories and the concrete shell, and a recuperator of the same refractories. The furnace chamber was 50 cm. square. With illuminating gas a temp. of 1750° was reached in 5.5 hrs. This was not the max. possible, but was limited by the refractories. Detail drawings are given. A tube furnace is described. This is essentially a long muffle, with flues in the walls for heating. The refractories are "special" and have a layer of insulating powder or insulating bricks between them and the concrete frame. This concrete frame is ironed as usual. The material to be heated passes through the tube on special refractory plates rolling on balls. This does away with the troubles incident to carriages on wheels. B.'s tunnel furnace is of the same design but the gases of combustion pass directly over the ware instead of through the flues as in the tube furnace. The special points in the tunnel furnace are insulation as described above and the ball bearing carriages. The tunnel furnace described was too short (15 m.) for the fullest regeneration of the heat in the ware. At 1200° it has a thermal efficiency of 78% and at 1400°, 70%. It is claimed that a furnace 30 m. long would give an efficiency of 85%. Much stress is laid on "special" refractories which are not described.

W. L. BADGER.

**Photometer liquids in tablet form.** W. HAUSMANN. *Z. wiss. Phot.* 17, 268 (1918); *J. Soc. Chem. Ind.* 37, 637A.—For greater convenience in handling, although with some loss of sensitiveness, photometer liquids are mixed with a sterilized agar-agar suspension, the mixt. being allowed to set in Petri dishes. Eder's soln. ( $HgCl_2 \cdot C_2O_4(NH_4)_2$ ) gives a colorless jelly in which a white opaque ppt. is formed on exposure to light. Rousin's liquid (Na nitroprusside- $FeCl_3$ ) gives a brownish colored jelly turning to a strong blue color.

E. J. C.

**Centrifugal pumps for dealing with liquids containing solid, fibrous, and erosive matter.** RICHARD C. PARSONS. *Engineering* 107, 150-1(1919).—The Stereophagus pump (*Engineering* 92, 444(1912)) consists of a conical impeller with curved blades working against a fixed blade in the casing. The action is similar to that of a lawnmower. The suction opening is a narrow slot to prevent the entrance of large pieces of solid matter. It is used for low-lift pumping of sewage. If larger pieces of solid matter or corrosive or erosive liquids are to be handled, the Flexala pump is recommended. This is a single suction open impeller volute pump. The back of the impeller is cast iron, on the face of which is vulcanized a rubber layer carrying flexible rubber vanes. If the liquid is very corrosive the whole inside of the pump is rubber lined.

W. L. BADGER.

---

**Acetylene generator.** O. M. FURR. U. S. 1,292,302, Jan. 21. \*

**Acetylene generator.** A. F. JENKINS. U. S. 1,292,327, Jan. 21.

**Gas-washing apparatus.** A. L. STEVENS. U. S. 1,292,125, Jan. 21.

**Apparatus for separating solid particles from gases.** W. J. BALDWIN. U. S. 1,292,561, Jan. 28.

**Filter for acids.** E. J. SWEETLAND, F. W. MANNING and W. S. HILPERT. U. S. 1,292,535, Jan. 28. A fabric adapted for use in filtering rancid fats or oils or other acid substances is formed of a woven wire cloth which may be formed, e. g., of brass or Cu, coated with a protecting layer of a phenolic condensation product.

**Viscometer.** A. S. DYSART. U. S. 1,292,276, Jan. 21. The viscosity of liquids is detd. by the rate of flow of the liquid through an orifice in the bottom of a bucket-shaped vessel which is allowed to float in the liquid. A depending annular flange at the upper end of the bucket forms an air-lock and prevents the vessel from sinking beyond a certain predetd. depth in the liquid.

S. C. L.

**Energy principle in the general theory of relativity.** A. EINSTEIN. *Sitzb. kgl. preuss. Akad.* 24, 448-59; *Sci. Abstracts* 21A, 353-4(1918).—E.'s impulse-energy principle is exhaustively examd. in the present paper. There are considered the formulation of the principle and the objections raised against it; the extent to which energy and impulse are independent of the choice of coördinates; and the energy of the spherical universe. The integral principle for an enclosed universe is evolved, and the ponderous mass of a closed system is evaluated and is found to be equal to the quantity which has been designated its energy. In conclusion, it is stated that for the formulation of the impulse-energy principle of a quasi-spherical (but not of a quasi-elliptical) universe, coördinates are to be preferred which are obtained by the stereo-graphical projection of the sphere upon a (three-dimensional) hyperplane.

H. JERMAIN CREIGHTON.

**Principal points of the general theory of relativity.** A. EINSTEIN. *Ann. Physik* 55, 241-4(1918); *Sci. Abstracts* 21A, 351-2.—The general theory of relativity rests upon 3 hypotheses which are not independent of each other, namely: (a) the relativity principle, by which natural laws are only statements of time-space coincidences and find a single natural expression in general covariant equations. (b) The principle of equivalence by which inertia and wt. are essentially equal. From this principle and the results of the special theory of relativity, it necessarily follows that the symmetrical fundamental tensor,  $g_{\mu\nu}$ , detcs. the metrical properties of space, the inertia behavior of bodies in it, and the gravitational effects. The space condition given by the fundamental tensor is designated as the G-field. (c) Mach's principle by which the G-field is detd. without residue by the masses of the bodies. Since mass and energy are the same according to the conclusions of the special relativity theory and the energy is formally described by the symmetrical energy tensor  $T_{\mu\nu}$ , it follows that the G-field is detd. by the energy tensor of matter. If it is correct that every empirical law must be brought into general covariant form, then the principle a possesses a significant heuristic force which is most valuable for the gravitational problem. Principle b has formed the starting point of the whole theory and brought about the existence of principle a, and it cannot be omitted so long as the fundamental ideas of the theoretical system are maintained. Mach's principle detcs. the space-time structure of the universe. -E. concludes that the geometrical shape of the universe deviates only slightly

from that of a spherical space, and that only locally, *e. g.*, as the shape of the earth's surface differs from that of an ellipsoid.

H. JERMAIN CREIGHTON.

**Polar and non-polar valency.** RAJENDRALAL DE. *J. Chem. Soc.* 115, 127-34 (1919).—In the light of recent theories of at. structure, De has discussed the structural significance of complex salts such as the cobaltammines and Pt-ammonium salts, and of compds. such as  $(CPh_3)_2$ ,  $C_2H_2$ , and the acetylides, and others, in relation to polar and non-polar valency.

R. E. HALL.

**The stratification of liquid films.** JEAN PERRIN. *Ann. phys.* 10, 160-84(1918).—Two black spots are visible on a soap film just before its rupture. They reflect the light very little, and are composed of a great number of spots, one within the other, of increasing blackness. If protected from air currents they may be preserved for some time. Their thickness, as measured by Reinold and Rücker, is from 6 to 12 millimicrons. P. describes five black spots, one within the other, which are distinguished by their brightness and color. They are observed microscopically, in a horizontal position, with autocollimation. A very intense Brownian movement is observed within the spots, which is a two-dimensional movement due to the bombardment by the air of particles of liquid in the film. The effect of adding various fluorescent materials is described, and the fringes produced are described in detail. The thickness is measured by an optical method. It is found that the thickness is always an even multiple of an elementary thickness of about 5 millimicrons. The effect of surface tension is discussed, and it is shown that the surface layer, in the case of sodium oleate, consists of oleic acid and the remainder contains free base. An actual sepn. is obtained by repeated sepn. of the surface layer, as by bubbling air through. It is shown, by measurements of the area of the surface and of the amt. of acid removed, that the layer is 2 mol. thick.

F. C. HOYT.

**Compressibility of aqueous solutions of casein and peptone.** SVEN PALITZSCH. Harvard Univ. *J. Am. Chem. Soc.* 41, 346-51(1919).—The compressibilities of both casein and peptone solns. decrease with rising concn. For the pressure range of 300 megabars, and the concn. of 10 g. to 100 g. of water, the compressibilities are (1) acid casein,  $40.6 \cdot 10^{-6}$ ; (2) alk. casein,  $40.5 \cdot 10^{-6}$ ; (3) peptone,  $39.0 \cdot 10^{-6}$ . The H-ion concn., soln. vol., and viscosity were measured; also the surface tension for the peptone solns.

R. E. HALL.

**New method for determining the allotropic transformation of nickel.** JÄNECKE. *Z. angew. Chem.* 31, I, 229(1918); *J. Soc. Chem. Ind.* 38, 43A.—Allotropic changes in metals are accompanied by a change in the rate of expansion, but this is so small as to be difficult to detect. The following method allowed the change to be observed over short as well as long intervals of time: A Ni cylinder 45 cm. high was inserted in a low-power press (3000 kg.) used for tensile and compressive strength tests, and heated by means of a resistance furnace; the variation in length produced a movement of the upper movable plate of the press and was registered on a scale indicating movements as small as 0.007 mm. The transformation temp. of Ni was found to be  $347-356^\circ$ ; the expansion graph consists of 2 straight lines, that above the transformation temp. being more steeply inclined.

E. J. C.

**Thermal conductivity of neon.** S. WEBER. *Proc. Acad. Sci. Amsterdam* 21, 342-56(1919).—See *C. A.* 12, 2469.

E. J. C.

**Determinations of the heat conductivity of selenium.** E. D. SAYCE. *J. Proc. Roy. Soc. N. S. Wales* 51, 356-63(1917).—In work by other investigators, attention has been concentrated mainly on the effect of illumination on thermal cond. In this paper the influence of method of prepn., the age of the specimen and the temp. of testing have been investigated, all measurements being made with the Se in darkness.

The method used was that of C. H. Lees (*Trans. Roy. Soc. London (A)* 1898, 399). The thermal cond. of vitreous Se at 25° was found to lie between 0.000293 and 0.000328, that of cryst. Se between 0.00070 and 0.00183. In general, the cond. increases with the temp. of prepn., but diminishes with age. The variation of cond. with temp. may be expressed by the equation  $K_t = K_{25} [1 + a(t - 25)]$ , in which  $a$  for vitreous Se ranges from 0.006 to 0.009, and for cryst. Se from 0.003 to 0.010. Values are expressed in absolute units.

D. MACRAE.

The effect of some simple electrolytes on the temperature of maximum density of water. ROBERT WRIGHT. *J. Chem. Soc.* 115, 119-26(1919).—The results affirm the law of Despretz that the lowering of the temp. of the max. d. of H<sub>2</sub>O produced by the addition of a solute is directly proportional to the concn. of the latter. With highly ionized electrolytes there are 2 independent effects, one due to the acid, the other to the basic radical. The lowering produced by such an electrolyte in mol. concn. can be calcd. by the addition of 2 moduli to the lowering produced by a mol. soln. of a standard substance, as *N* HCl, which gives a lowering of 5.2°. Acid salts of dibasic acids behave normally, but the neutral salts of such acids and the salts of bivalent metals do not follow any simple rule. Feebly ionized org. acids show abnormal effects, but their highly ionized salts are normal.

R. E. HALL.

Molecular attraction and attraction of mass and some new gas equations. JAMES KAM. Univ. Bristol. *Phil. Mag.* 37, 65-97(1919).—A mathematical treatment of the gas laws introducing some new equations, including the influence of temp. on some of the van der Waals consts.

S. C. L.

The influence of temperature on homogeneous gas reactions. GEORGE W. TODD AND S. P. OWEN. London. *Phil. Mag.* 37, 224-30(1919).—The general assumption is made that only mols. possessing kinetic energy in excess of a definite minimum value can enter into chem reaction with other gas mols. From Maxwell's distribution theorem a simple expression is deduced for the number of gas mols. per cc. having velocities greater than any particular value. From this it is shown how the velocity const. of a gas reaction varies with the temp. The usual form of expression for variation of equil. with temp. is also obtained.

S. C. L.

Joule-Thomson effect and the equation of state for gases at small pressures. M. JAKOB. *Ann. Physik* 55, 527-44(1918); *Sci. Abstracts* 21A, 381.—The equation of state of a gas may be derived if, besides its sp. heat ( $c_p$ )<sub>0</sub> for  $p = 0$ , the integral Joule-Thomson effect for an infinitesimal pressure is given as a function of the initial pressure  $p$  and temp.  $T$ , also an isothermal of the state is given for the detn. of the arbitrary integration function when the integration is made with respect to  $T$ . In this manner there is derived the equation of state:  $v = RT/10^4p + A'p^2 + B'p^3 + C'p^4 + D' + E'T$ , where  $R$  is the gas const., and  $A'$ ,  $B'$ ,  $C'$ ,  $D'$  are functions of  $T$ , and  $E'$  is a detd. rational integral function of  $p$ . This equation has been found to hold at pressures as high as 1000 atms. at 200°. For  $p = 0$  the following equation has been evolved:  $\delta(pv)/\delta p = D' = (-191310/T^4) + (10229/T^3) - (147.63/T^2) + (0.08973/-T) + 0.00065708$ . The inadmissibility of the identification of an ideal and of a real but infinitely diluted gas is discussed; the general form of the equation of state of a real gas is developed; the equations of state and the Joule-Thomson effect according to van der Waals and Berthelot, and the Joule-Thomson effect of infinitely dil. air according to theory and expt. are considered; and the Joule-Thomson effect of other gases is calcd. from that of air, according to the method of corresponding states. The equation of state is found to hold good for very low pressures as for very high, and to be of general applicability.

H. JERMAIN CREIGHTON.

A tyndallimeter for the examination of disperse systems. RICHARD C. TOLMAN AND ELMER B. VLIET. *J. Am. Chem. Soc.* 41, 297-300(1919).—A convenient form of

tyndallmeter is described which may be constructed from stock materials and which can be effectively employed in detg. the strength of Tyndall beam in suspensions, colloidal solns., smokes and mists.

E. B. SPEAR.

**Relation between the intensity of Tyndall beam and concentration of suspensions and smokes.** R. C. TOLMAN, L. H. REYERSON, E. B. VLIET, R. H. GERKE AND A. P. BROOKS. *J. Am. Chem. Soc.* **41**, 300-4(1919).—By means of the tyndallmeter mentioned in the preceding abstract measurements were made to det. the relation between the strength of the Tyndall beam and the concn. of a silica suspension in water, and also the concn. of  $\text{NH}_4\text{Cl}$  smokes in air. The results show a strict proportionality over a wide range, i. e., 0.05 to 2 g. per l. for silica suspensions and from 0.02 to 1.2 mg. per l. in the case of  $\text{NH}_4\text{Cl}$ . At higher concns. the proportionality fails because the solns. are so opaque that a considerable portion of the light is absorbed.

E. B. SPEAR.

**The disappearance of smoke in a confined space.** RICHARD C. TOLMAN, E. B. VLIET, W. MCG. PHIRCE AND R. H. DOUGHERTY. *J. Am. Chem. Soc.* **41**, 304-12 (1919).—The rate of disappearance of smokes was found to be a function of the stirring, the size of the particles, and of the concn. Smokes were made from acetanilide, benzoic acid, and rosin by exploding each with a blasting cap. Oil smokes were produced by means of a thermal effect whereby the size of the particles could be varied. Stirring accelerates the disappearance because the particles are brought more frequently in contact with walls of the container. Small particles, because of the greater velocity of diffusion, coagulate more quickly, hence the rapidity of the disappearance is increased. If the size of the particles remains the same increasing the concn. causes a more rapid disappearance owing to the greater chance of hits between the particles and also because of the enhanced effect of the containing walls. From this the authors conclude that it is impossible to raise the optical density of smoke beyond a certain value by further introduction of smoke material.

E. B. SPEAR.

**A study of the forms assumed by drops and vortices of a gelatinizing liquid in various coagulating solutions.** EMIL HATSCHKE. *Proc. Roy. Soc. London (A)* **95**, 303-15(1919).—According to D'Arcy Thompson the shapes of the simpler organisms are forms of equil. such as are assumed by fluid bodies under suitable conditions. The various stages of formation of these shapes were studied by allowing drops of concd. gelatin to fall into solns. containing different coagulating substances. The results are detd. by many factors, such as the concn. of the gelatin, density of the coagulating soln., nature of the solute, temp. of both solns., and distance of the orifice of the instrument delivering the drops from the coagulating soln. A 14% gelatin soln. at 25 to 30° dropped into an  $\text{Al}_2(\text{SO}_4)_3$  soln. having  $d_{18}$  1.030 gave a vortex mushroom effect. Cf. *C. A.* **12**, 2474. The drop had ribs on the bell and disk. The portion remaining on the surface exhibited a stellate appearance. The formation of the ribs and the star is due to shrinkage. The ribs do not appear when the gelatin is dropped into a 9% gum arabic soln. When  $\text{K}_4\text{Fe}(\text{CN})_6 \cdot 3\text{H}_2\text{O}$  or tannin is employed as coagulant the drops resemble the red corpuscles of the blood. The addition of certain salts causes the drops to simulate the forms of some lower organisms.

E. B. SPEAR.

**An oscillation method for measuring the size of ultramicroscopic particles.** P. V. WELLS AND R. H. GERKE. *J. Am. Chem. Soc.* **41**, 312-29(1919).—Solid suspensions in air are dealt with. A modification is described of the method of measurement based on the velocity of particles in an elec. field, the oscillation amplitudes of the particles in an alternating field are utilized. The method renders possible the precise detn. of the Stokes' law size of a single particle. The smoke particles were found to be  $0.8 - 2.80 \times 10^{-7}$  cm. in diam., with an average deviation of 1.8%. Frequency

and Ogive curves are given for smokes made by detonating commercial lubricating oil with blasting caps. These curves clearly show the agglomeration of the particles with time.

FELIX A. ELLIOTT.

Production of high pressures by electrolysis. K. WILKENS. *Chem. Ztg.* 42, 428(1918); *J. Soc. Chem. Ind.* 37, 661A.—If water is electrolyzed in a completely filled vessel, the gases produced can only occupy the space of the decomposed water, that is, in 1 ampere-hour, 624 cc. of gases must occupy a vol. of 0.3354 cc. and will be under a pressure of 1860 atms. When only  $\frac{9}{10}$  of the vol. of the vessel is filled with water and the remaining  $\frac{1}{10}$  occupied by air, the pressure after electrolyzing for 1 hr. (with 1 amp.) will be 7 atms.; after 19 hrs., 61; after 50 hrs., 269; and after 1000 hrs., 1433 atms.

E. J. C.

Proof of the assumptions underlying the thermodynamic potentials. M. B. WEINSTEIN. *Ann. Physik* 55, 497-526; *Sci. Abstracts* 21A, 381-2(1918).—W. has developed theoretical methods by which the objections raised against previous methods that have been applied to the proof of the fundamental form of the thermodynamic potentials may be overcome. It is shown that from purely thermodynamic considerations the proportionality between osmotic pressure and concn. cannot be established; also that the same holds for the temp. relation, and, generally, processes involving diffusion are irreversible. The connection between the Arrhenius cond. laws is capable of treatment by the thermodynamic equations. Further formulas are evolved for the fundamental equations of equil. The treatment of the subject is mathematical throughout.

H. JERMAIN CREIGHTON.

The lag of thermometers with spherical and cylindrical bulbs in a medium whose temperature is changing at a constant rate. A. R. McLEOD. Cambridge Univ. *Phil. Mag.* 37, 134-44(1919).—A mathematical treatment with special reference to aeronautical application. For speeds of 60-100 miles per hr. for cylindrical or spherical thermometers with the same vol. expansion the total lags would be: For Hg (sphere)  $1.61^\circ$  and for cylinder ( $10 \times 0.36$  cm.)  $0.85^\circ$ ; for alc. (sphere)  $1.62^\circ$  and for cylinder ( $10 \times 0.36$  cm.)  $0.45^\circ$ .

S. C. L.

X-Ray analysis and the assignment of crystals to symmetry classes. ALFRED E. H. TUTTON. *J. Wash. Acad. Sci.* 9, 94-9(1919).—T. summarizes a paper by Wherry (*C. A.* 12, 2155) but concludes that the allocation of a crystal in two different classes is unacceptable, holding that: the space-lattice det. the crystal system, while the points in the lattice det. the particular class; there are 14 space-lattices, and these are holohedral, each point of the lattice representing a single molecule or a small group of 2, 3 or 4 mols.; the point-systems of lower symmetry are not space-lattices, but Sohncke regular point-systems; diamond shows no polarity and is therefore holohedral; and the structure of pyrite is not a space-lattice.

S. G. GORDON.

Reply to Dr. Tutton's discussion of the assignment of crystals to symmetry classes. EDGAR T. WHERRY. *J. Wash. Acad. Sci.* 9, 99-102(1919); cf. preceding abstr.—W. points out that the habit and etch-figures of the diamond are tetrahedral, and the absence of elec. polarity cannot alter the fact. His new explanation of the discrepancy is that the structure as a whole is holohedral, while the symmetry of the unit cells is tetrahedral (which is reflected in the habit and etch-figures), as shown by X-rays. X-ray study has further shown the existence of other than the 14 Bravais space-lattices. The structure of pyrite is a compd. lattice, composed of two interpenetrating simple ones. The view that mols. rather than atoms occupy points of space-lattices has been definitely disproved by X-ray study of crystals.

S. G. GORDON.

Liquid crystals of agaricinic acid. PAUL GAUBERT. *Compt. rend.* 168, 277-9 (1919); cf. Thoms and Vögelsang, *C. A.* 2, 657.—The crystals lose their water of crystn.

a little above  $100^{\circ}$ , becoming transparent and monorefringent. If the acid has not been heated above the fusing temp. it shows the following phenomena upon slow cooling: (1) Under the microscope the monorefringent droplets, at first clear, become cloudy by the formation of globules more refringent than the liquid. These last are monorefringent and some among them occasionally show angular contours; at the beginning of their formation they show alignments recalling the axes of a crystal of the cubic system, the whole making a soft mass having the consistency of vaseline. This formation resembles that of AgBr when heated between  $400$  and  $450^{\circ}$ . On further cooling the prepn. becomes solid, the crystals preserving their characters. They may also be transformed either to a monorefringent solid mass, probably corresponding to that which was observed before fusion, or to birefringent solid spherulites. (2) The monorefringent droplets may become cloudy as in the preceding case, but yield elongated lozenge crystals identical with those of cholesteryl glycolate, but much less birefringent. These crystals are quite fluid, liquefying under the least pressure and form themselves around bubbles of gas into spherulites in which the principal index of refraction  $n_z$  coincides with the radial direction. Between two plates of glass the crystals disappear and are replaced by the outlines into which the cryst. mols. have oriented, in such a manner that their optic axes are perpendicular to the plates. By cooling, the mass gradually solidifies, the liquid crystals becoming more viscous, sometimes preserving their characters, but more frequently passing into a new modification of solid spherulites more birefringent than the liquid crystals. These melt at  $100^{\circ}$ , have  $n = 1.501$ , though when hydrated  $n$  is about  $1.515$ . L. W. RIGGS.

**The classification of mimetic crystals.** EDGAR T. WHERRY AND E. Q. ADAMS. *Bur. Chem. J. Wash. Acad. Sci.* 9, 153-7 (1919).—Instead of describing all cases of imitation of the symmetry of one crystal class by crystals really belonging to another class by the general prefix pseudo-, which is all that is usually done, it is recommended that the different types of relationship be clearly distinguished, and a series of appropriate prefixes for this purpose is proposed. E. T. WHERRY.

**Artificial coloration of liquid crystals.** PAUL GAUBERT. *Compt. rend.* 167, 1073-5 (1918); cf. *C. A.* 3, 139; 4, 138, 732; 7, 1484; 8, 505, 1224, 1370.—A discussion of optically negative and optically positive liquid crystals, colored with iodophenol, is given, with special reference to the phenomena of birefringence and pleochroism. The results with reference to the rule of Babinet, and with relation to the influence of birefringence upon pleochroism, are conformable to those obtained by previous study of solid solns. (*C. A.* 12, 2548), the properties of the latter being different from those of mixed crystals. L. W. RIGGS.

**Determination of the principal indices of refraction of anisotropic substances by the observation of the retardation in thin plates in oblique parallel light.** A. LEDOUX. *Bull. soc. franc. min.* 40, 119-57 (1917).—An elaborate mathematical discussion of this method is given, and simplified directions for detg.  $n$  under different conditions are furnished. E. T. WHERRY.

**The optical properties of magnesium chloroplatinate.** PAUL GAUBERT. *Bull. soc. franc. min.* 40, 177-82 (1917).—Previous work on this substance having led to discordant results, some small crystals were further studied. As ordinarily obtained, this crystallizes with  $7\text{H}_2\text{O}$ , but on polishing a yellow powder with  $6\text{H}_2\text{O}$  is produced; on standing this changed back to the original compd., the new formed material taking up parallel positions on the original crystal. The amt. of  $\text{H}_2\text{O}$ , and accordingly the  $n$ s, vary somewhat with the humidity of the atm. Measurements with the reflectometer gave  $\omega_{[D]^{16^{\circ}}}] = 1.5608$ , and by study in convergent polarized light for D was found to be approx. 1.91. Values for other wave lengths are given. A double cyanoplatinate

of Na and K was also studied, and the lowest  $n$  found to be for D 1.6088 and the highest around 1.90. Similar values had previously been found for the K Li and Rb Li salts.

E. T. WHERRY.

**Stable silver nitrate solution.** F. LIEBERT. *Chem. Weekblad* 16, 74(1919).—By exposing  $\text{AgNO}_3$  soln. to light till all the org. matter has reacted and filtering through asbestos, a stable soln. is obtained. It can be kept in a clear glass bottle in full daylight for more than a year.

### 3. SUBATOMIC PHENOMENA AND RADIOCHEMISTRY.

---

GERALD L. WENDT.

**Radium.** R. B. MOORE. U. S. Bureau of Mines, Golden, Colo. *Bull. Am. Inst. Mining Eng.* 1918, 1672-4; cf. *C. A.* 13, 397.—Discussion of address on radium (*C. A.* 12, 2157). S. C. L.

The aggregate recoil of radioactive substances emitting  $\alpha$ -rays. ROBERT W. LAWSON. Vienna Ra. Inst. *Nature* 102, 464-5(1919).—From his study of the properties of the active deposit of Ra, Ratner has advanced the view (*C. A.* 13, 282) that the spontaneous transference of active matter from the surface of a plate, covered with the active deposit of Ra, to other objects placed near it is due neither to a slight volatility of the active deposit at ordinary temp., nor to radioactive recoil, as suggested by Makower and Russ (*C. A.* 4, 1937), and that the nature of the phenomenon still remains undisclosed. L. now takes exception to this conclusion and makes a preliminary announcement of the results of an investigation which supports the view as advanced by Makower and Russ that the phenomenon in question is due to the recoil of a complex cluster of the atoms of the radioactive matter when one of the atoms contained in it disintegrates with ejection of an  $\alpha$ -particle. It is considered that a transference of active matter by virtue of the recoil resulting from the evolved  $\beta$ -particle is theoretically possible but incapable of practical realization. W. H. ROSS.

**End-product of thorium.** J. R. COTTER. Trinity Coll., Dublin. *Nature* 102, 425(1919).—Thorianite was examd. with a view to the quant. detn. of Tl which had been suggested by Soddy (*C. A.* 11, 2167) as a possible end product of Th. No Tl could be detected in the mineral, and it is claimed that it does not contain as much as even 0.005% of this element.

FREDERICK SODDY. *Ibid* 444.—S. concurs with the result found by Cotter and expresses the opinion that there is now very little exptl. evidence in favor of the view that Tl is an end product of Th. Reference is made to unpublished work that has been carried out at the Ra Inst., Vienna, which indicates that both the isotopes of thorium-Pb are stable.

W. H. ROSS.

**A study of the emanation method of determining thorium.** G. H. CARTLEDGE. Univ. Chicago. *J. Am. Chem. Soc.* 41, 42-50(1919).—The circulation method of detg. Th by means of Th Em has been modified so as to furnish a practical and reliable method for detg. Th quantitatively by means of the emanation electroscope. Instead of a closed cycle for the circulation of the gases, the emanation was pumped through the ionization chamber only once. A special device for the regulation of the pressure in the chamber is described. A method was worked out for preparing radiochemically complete solns. of monazite sand with an accuracy of 1.5%.

S. C. LIND.

**Radioactivity and the coloration of minerals.** E. NEWBERRY AND HARTLEY LUYTON. *Mem. Proc. Manchester Lit. Phil. Soc.* 62, III, 1-16(1917-8).—See *C. A.* 12, 2076.

E. J. C.

**The atomic structure of carborundum determined by X-rays.** C. L. BURDICK AND E. A. OWEN. Sheffield, Alabama. *J. Am. Chem. Soc.* 40, 1749-59(1918).—The internal crystal structure of carborundum has been detd. using the method of crystal reflection of X-rays as employed by Bragg. A target of pure Pb was employed in the generation of X-rays. The results show that the Si and C atoms are each arranged on face centered rhombohedral lattices, very nearly cubic, displaced with respect to one another along the hexagonal axis by 0.36 of the basal plane (111) spacing. The structure is very similar to that of the diamond. From the X-ray crystal measurements the density of carborundum was calcd. to be 3.11 and was found by expt. to be 3.123.

S. C. LIND.

**The absorption of X-rays.** TYCHO E. SON AUREN. Nobel Inst., Stockholm. *Phil. Mag.* 37, 165-207(1919); cf. *C. A.* 12, 1357.—In order to study the relation between at. number and the absorption of X-rays A. has devised a compensation method for detg. the relative absorption coeffs. of X-rays relative to that of water. A large number of elements have been dealt with, most of them in the form of an aq. soln. of a suitable compd., though for the lighter elements which constitute org. substances, the pure liquid org. compds. were preferred. The coeffs. of compds. are comprized additively by the sum of the coeffs. of the component atoms. No difference in coeff. could be observed for the same element in different valences. The state of aggregation also makes no difference in the absorption with the possible exception of C. Nearly all elements from H through Ag and Pb have been detd. for four different wave lengths,  $\lambda = 0.38, 0.36, 0.34,$  and  $0.30 \times 10^{-8}$  cm. Assuming that absorption for H is exclusively due to scattering by the electron combined with the nucleus, scattering for other elements would likely be due solely to the electrons constituting the outer layer. By aid of the relative at. adsorption for H, the number of outer electrons can be estd. for the lighter elements. For different elements the at. absorption increases by groups nearly proportional to the at. number. Assuming that the at. number gives the number of electrons of the nucleus, the distribution of electrons between outer and inner region may be estd. The number of electrons for the lighter elements seems to be the

same for those in the same vertical row of the periodic system, and therefore the distribution of electrons appears to be in close connection with the periodicity of the chemical properties of the elements as expressed by that system. S. C. LIND.

Calculation of scattered radiation from a plate exposed to a beam of X-rays. OSKAR KLEIN, Nobel Inst., Stockholm. *Phil. Mag.* 37, 207-14 (1919).—Mathematical calculation of scattering of X-rays by a solid layer of substance. S. C. L.

Ionization and resonance potentials for electrons in vapors of magnesium and thallium. PAUL D. FOOTE AND FRED L. MOHLER. U. S. Bureau of Standards. *Phil. Mag.* 37, 33-50 (1919).—A continuation of the work of Foote (*C. A.* 12, 2277) to extend to Mg and Tl vapors. The exptl. values for Mg are 2.65 v. for resonance potential and 7.75 v. for ionization potential. The corresponding values calcd. from the quantum relation are 2.70 and 7.61 v., resp. For Tl the observed values are 1.07 and 7.3 v.; the theoretical value for the resonance potential of Tl vapor is 1.07, the theoretical value for ionization potential being unknown. The ionization potential of Mg is detd. by the limit of the series  $1.5 S-m\phi$  and the resonance potential by the first line in the series  $m = 2$ . For Tl the resonance potential is detd. by the shorter wave length member of the first term of the principal series of doublets. No known series for Tl has a convergence frequency greater than 49263. The observed ionization potential for Tl suggests an undiscovered series of single lines converging at  $\nu = 1.5 S = 57000$  to 60000. Evidence is furnished that the single-line spectra of Mg and Tl are  $\lambda = 4751$ , and  $11513 \text{ \AA}$  units, resp. The general behavior of metals in the same group of the periodic table appears to be identical as regards ionization and resonance potentials. From a large number of expts. on 7 different metals the writers give a mean value of Planck's const. of  $h = 6.55 \cdot 10^{-27}$  erg. sec. S. C. LIND.

The light from mercury vapor. C. D. CHILD. Colgate Univ. *Phil. Mag.* 37, 61-4 (1919).—A discussion of Strutt's (*C. A.* 12, 1359) recent conclusion that the luminosity produced in passing elec. discharge through vapors at low pressures is due to negative electrons. C. had earlier concluded (*C. A.* 8, 2522) that the light is due to the recombination of positive and negative ions. C. holds that the matter is not necessarily decided by Strutt's expts. and that further observations are required to settle it definitely. S. C. L.

Radium and uranium in 1916 (Hess) 9. A tyndallmeter for the examination of disperse systems (TOLMAN, VLIET) 2. Examination of metals by X-rays (PILON) 9. The assignment of crystals to symmetry classes (TUTTON), (WHERRY) 2. Polar and non-polar valency (DE) 2.

Radium from carnotite ore. H. N. MCCOY. U. S. 1,292,341, Jan. 21. Ore containing 10% carnotite and 90% of sand and earthy materials is ground and treated with about 50% its weight of  $H_2SO_4$  of about 60% strength. The mixt. is dried at a temp. of  $100^\circ$  until the  $H_2O$  has been largely driven off and is then baked at  $250^\circ$ . The product is a green solid containing sulfates of the metals present such as V, U, Al, Fe, Mg, Ca, Ba and Ra. This green solid is stirred with  $H_2O$ , decanted and the decanted soln. is filtered. The material is thus sepd. into 3 portions: (a) a green soln. principally composed of sulfates of V, U, Al, Fe and Mg; (b) a residual coarse sand without value; and (c) a fine slime made up of the sulfates of Ca, Ba and Ra together with siliceous materials. One ton of the ore yields about 400-600 lbs. of this Ra-bearing slime. A portion of this slime concentrate, having a dried weight of 220 lbs., is wetted with 200 lbs. of  $H_2O$  and mixed with 900 lbs. of a 30% aq. soln. of HF to furnish a sufficient proportion of HF to combine with the silica present and with 20 lbs. of concd.  $H_2SO_4$  and the mass is stirred for 3-8 hrs. to complete the reaction. The undissolved

residue, having a dry weight of usually about 20 lbs., contains practically all the Ra, together with sulfates of Ca and Ba. This residue is then further concd. and purified as may be desired by any suitable method.

#### 4. ELECTROCHEMISTRY.

COLIN G. FINK.

Output of the largest generating systems. ANON. *Elec. World* 73, 632-3(1919).—Data on output and load factor of 46 companies in U. S. and Canada. Among the electrochemically important: Niagara Falls Power Co., 2 billion kw. hr. yearly output at 92.2% yearly load factor; Ontario Power Co., 1,600,000,000 kw. hr., 81.9%; Toronto Power Co., 900,000,000 kw. hr., 81.9%.  
C. G. F.

The electrometallurgical industries of Scandinavia. KNUDSEN. *J. four Elec.* 28, 17-8(1919).—Sweden: The present production of elec. furnace Fe is 100,000 tons per year (67,057 in 1917 and 44,737 in 1916). Elec. furnace Fe is  $\frac{1}{8}$  the total production of Swedish Fe and this percentage will be increased by new installation at Trollhättan and Porjus. New furnaces will increase the production of elec. steel over the 10,664 tons from 25 furnaces in 1917. The production of ferro-alloys showed a loss for 1918. Norway: War-time production of  $\text{NH}_4\text{NO}_3$  has turned to  $\text{Ca}(\text{NO}_3)_2$  for fertilizer. Carbide manuf. is naturally changing to cyanamide; a plant has been built for converting carbide to EtOH by the Utheim process. The exportation of ferro-alloys decreased in 1918 while elec. furnace production of Fe and steel did not increase even with the scarcity and high price of Fe during the war.  
LOUIS JORDAN.

A technical description of industrial electric furnaces. JEAN ESCARD. *Rev. gén. Elec.* 4, 575-91(1918); illus.—A description of the general types of arc, resistance, and induction furnaces together with several types of special applications; viz., a furnace for the production of powdered metals, a furnace operating under high pressure (2,000-2,500 kg. per sq. cm.) equally adapted for vacuum work, furnaces heated by the resistance of fused salts, and a C block furnace. Installation, refractory linings, and methods of connecting with d. c. and single and polyphase a. c. current supply are considered.  
LOUIS JORDAN.

Temperature uniformity in an electric furnace. JOHN B. FERGUSON. *Chem. Met. Eng.* 20, 283-8(1919).—See C. A. 13, 536.  
E. J. C.

Electric steel. J. ESCARD. *Rev. gén. sci.* 29, 366-73, 401-13(1918).—A general discussion is given of the whole subject. The article is liberally illustrated with photographs and diagrams. The pig iron Héroult furnaces at Sault St. Marie, and the Keller blast furnace at Trollhättan (Sweden) are described. The following steel furnaces are discussed in detail: the Héroult Bessemer, the Stassano, Rennerfelt, Girod, Keller, Chaplet, Nathusius, Hiorth, and the Röchling-Rodenhauser.  
C. H. ELDRIDGE.

The electric furnace and its application in the manufacture of industrial products. J. ESCARD. *L'industrie chimique* 5, 214-8, 253-5, 284-6, 315-7(1918); 6, 8-12(1919).—A detailed illustrated review covering the elec. production of H, P, As, Si, B, graphite, Ba salts, BeO, fused  $\text{SiO}_2$ , ZnO, ferrites of Na, Ca, Sr and Ba, glass, cements, ZnS,  $\text{CCl}_4$ ,  $\text{S}_2\text{Cl}_2$ , and  $\text{CS}_2$ . Cf. following abstract.  
C. G. F.

The preparation in the electric furnace of some metals of industrial application. JEAN ESCARD. *Rev. gén. Elec.* 4, 375-86(1918).—A comprehensive discussion of the various methods of prepn. (with many working details) of the metals and alloys of Ba, Ca, Be, Co, Ni, Ti, Mn, Cr, Mo, W and V, with data on their chem. and physical

properties and uses. Some Ca-Al alloys (prepd. by electrolysis of  $\text{CaCl}_2$  in the presence of Al) are harder than Al; Ca-Al alloy is of value in removing gases ( $\text{H}_2$ ,  $\text{O}_2$ ,  $\text{N}_2$ ) from molten metals. Co in special steels gives remarkable properties and Co-Cr alloys are hard and resistant to corrosion and oxidation at high temp. The ternary alloy, Cr-Cu-Ni, is very resistant to acids. W in artillery projectiles increases the penetration of the shell. W-Mo thermocouples are used for temperature, above the range of Pt-Pt Rh couples (*C. A.* 7, 734, 1330). W tubes and crucibles for elec. furnaces withstand very high temp., comparable only to C, and possess advantages over C because of the low sp. heat of W and the absence of the carburizing of metals under treatment. Cf. preceding abstr. LOUIS JORDAN.

**Manufacture of ferro-alloys in the electric furnace.** R. M. KEENEY. *Bull. Am. Inst. Mining Eng.* 1918, 1651-4.—A discussion (cf. *C. A.* 12, 2164). E. S. BARDWELL states that in production of Fe-Mn almost nil volatilization losses of Mn take place in small (1500 k. v. a.) low volt (65 v.) furnaces, and that slag losses are much lower than in large furnace of 3000 k. v. a. and 100 volts. High voltage gives irregular working, overheating in spots (high volatilization losses), accompanied by cooler areas which cause the partially reduced Mn to pass into the slag. Substitution of coke for coal will reduce resistance and with low voltage will bring about steadier operating conditions than obtain in high voltage furnaces. Slags containing only 3% of total Mn in the ore have been obtained in small, low-voltage furnaces. A thorough study of furnace conditions should reduce losses in high-voltage large furnaces. Mr. H. W. GILLET questions Mr. Keeney's figures that C in ferro-U must be over 3.5% to hold large amts. of U. Gillett, by using excess of  $\text{UO}_2$  over C in the charge has produced ferro-U containing 50-70% U and with C below 2%. C. H. ELDRIDGE.

**Uses electric furnace in malleable foundry.** F. L. PRENTISS. *Iron Age* 103, 537-43 (1919).—The Kranz Triplex Process is used in the foundry of the Nat'l Malleable Castings Co., of Cleveland. An extended description is given of the equipment and floor plans of this foundry. The triplex process is designed to overcome the difficulties resulting from the presence of relatively high C, Mn and Si in the Fe. Two tons of metal tapped from the cupola is refined in a Bessemer furnace, and then added to 10 tons of cupola Fe to reduce the impurities in it. The resultant mixt. is charged into the elec. furnace for final refinement. Two 15-ton Héroult furnaces are used for its last refining. The process for casting steel anchor chain is described. The chain is heat-treated in two Bailly elec. furnaces. Cf. following abstr. W. E. RUDER.

**Electric furnaces of the resistance type used in the production of essential war materials.** T. F. BAILY. Alliance, Ohio. *Trans. Am. Electrochem. Soc.* 35, preprint (1919).—The resistance elements consist of carborundum fire sand troughs, set on fire brick piers within the furnace chamber proper, and filled with broken C. The elec. current is led into the resistor at the end of each trough by means of C or graphite electrodes. The three 900-kw. heat-treating sets for heat treatment of cast steel chain for the Emergency Fleet Corporation are described at full length. Each equipment consists of one 600-kw. furnace for heating the anchor chain for hardening, a 300-kw. furnace of the same general dimensions for the drawing operation, and a concrete water pit for quenching, as well as a motor-driven winch in front of each furnace for handling the chains into, through and out of that furnace. Each furnace is 8.5 m. long by 5.0 m. wide. The entire length of the equipment is 40 m. The transformer equipment for supplying electricity to the furnaces consists of three 300-kw. 60-cycle, single-phase transformers with their high-tension side wound for 11,000 volts. C. G. F.

**Saving the waste with an electric furnace.** C. B. MERRICK. *J. Elec.* 42, 30 (1919).—A two-phase Rennerfelt furnace of 750 lbs. capacity installed in a foundry has

been found useful for recovering scrap metals which could not be used in a cupola and in producing small batches of castings of special quality. W. E. RUDER.

**Electric smelting on the Pacific Coast.** W. L. MORRISON. *J. Elec.* 42, 67(1919).—The possibility of making ferro-alloys in the Northwest is cited. As now applied, 25 to 100 kw. single-phase furnaces or pots are used almost universally. These pots vary from 10 in. inside diam. to 24 in. and from 24 to 36 in. in height. When filled with alloy they are broken open. The electrodes are made at the home plant. The smelting of silico-manganese is successfully carried out. W. E. RUDER.

**Melting brass in a rocking electric furnace.** H. W. GILLETT AND A. E. RHOADS. *Bur. Mines, Bull.* 171, 126 pp.(1918).—The general problem of elec. brass furnaces is discussed with the advantages and limitations of various types of furnaces that have been commercially tested; *vis.*, Helberger, Hoskins, Baily, General Electric, Snyder, Rennerfelt, Bennett, Hering, Ajax-Wyatt, Foley, and Northrup. The construction of an indirect arc rocking furnace (cf. *C. A.* 12, 1728) is described and details of exptl. heats for both lab. and com. size furnaces are given. Metals charged included red and yellow brass, Mn-bronze, Ni-brass, and Cu-castings; all were melted with low metal loss. LOUIS JORDAN.

**Electric arcs.** J. C. MACGREGOR-MORRIS. *Engineering* 107, 214(1919).—A detailed account of two lectures delivered at the East London College. The author points out that a great deal of useful work has been done recently on arcs, but that a great deal remains to be done. C. H. ELDRIDGE.

**Electrostatic precipitation.** O. H. ESCHOLZ. *Bull. Am. Inst. Mining Eng.* 1918, 1654, 1775.—A discussion of a paper abstracted in *C. A.* 12, 2166.

H. JERMAIN CREIGHTON.

**Electric precipitation of fumes.** F. MICHEL. *Rev. gén. sci.* 29, 456-68(1918).—A complete discussion of the Cottrell system. History and theory are given, and some typical installations are described. C. H. ELDRIDGE.

**The Cottrell electrostatic recovery process of flue dust and fumes.** H. J. BUSH. *J. Soc. Chem. Ind.* 37, 389-91R(1918).—A review of the development of the Cottrell process and a short description of a number of plants. H. JERMAIN CREIGHTON.

**Electric precipitators.** E. E. THUM. *Chem. Met. Eng.* 20, 59-64(1919).—A summary of observations taken from plants where the Cottrell process is installed. The sphere of usefulness of the process, the power equipment, the current characteristics, the advisability of interrupting the gas current during shaking, electrodes and insulators, the replacement of punctured insulators, gas distribution, and the effect of temp. variations are discussed. If differential pptn. is to be attempted, close temp. control will be necessary, and in this case the treater pipes may be surrounded with adjustable louvers so that cold air may be admitted or excluded. The efficiency of the pptn. of fume-laden gases may be increased by water sprays discharging into the flue leading to the pptg. plant. H. JERMAIN CREIGHTON.

**Notes on electrostatic precipitation.** H. D. BRALEY. *Trans. Am. Electrochem. Soc.* 35, preprint(1919).—A review of the general question of electrostatic pptn. of dust and fume, including the removal of emulsified  $H_2O$  from oil. The following applications are discussed: recovery of metallic dust from gas fumes given off from ore smelters, roasters and blast furnaces, the most important of which are the Pb and Cu recoveries; recovery of Sb, S and As from Cu and Pb-bearing ores; recovery of potash from cement dust in cement mills treating potash-bearing limestone. Detailed data are given for the cost of different plants, operating costs, values recovered and profits secured. Gas treaters of the tube and the plate type and of the plate type employing  $H_2O$  film, as well as liquid treaters employing stationary electrodes and rotating elec-

trodes are discussed; also temp. control, the gas velocity in the treaters, the direction of the gas flow, the capacity of the elec. equipment, the operating voltage, and the elec. app. are discussed.

H. JERMAIN CREIGHTON.

**Aluminium-manufacturing processes used in Europe.** O. NISSEN. *Chem. Met. Eng.* 19, 804-15(1918).—An historical review of the com. developments and researches. The various bauxites and processes employed for the prepn. of pure alumina, as well as the methods of manufacturing C electrodes, are described. The elec. installation, the industrial applications of Al, and the world's production of bauxite are discussed. The cost in francs of Al per kg. is estd. on pre-war conditions as follows: 35 kw.-hrs., 0.25; 2 kg. alumina, 0.50; 0.8 kg. electrodes, 0.28; 0.12 kg. cryolite, 0.05; 0.05 kg. fluorine, 0.03; 0.25 working hours, 0.15; miscellaneous, 0.15, making a total of 1.41 francs. The paper is illustrated with numerous diagrams of furnaces, including one of the Serpek AlN furnace.

H. JERMAIN CREIGHTON.

**Electrolytic zinc.** C. A. HANSEN. *Bull. Am. Inst. Min. Eng.* 1918, 1639-41; cf. *C. A.* 12, 652.—Additional data are given upon the effect of temp. upon the behavior of Zn cells. Current efficiencies obtained indicate a doubling of the corrosion rate with each 21.7° rise in electrolyte temp. Parallel tests made by merely suspending sheets in solns. at different temps. (not cathode) indicate no definite temp. coeff. In the temp. range 40-45°, evapn. of soln. from electrolyte surface accounted for 87% of the energy dissipated at the surface. The fundamental necessity of pure electrolyte is emphasized.

W. E. RUDER.

**Electrolytic production of antimony directly from stibnite ore.** D. J. DEMOREST. *J. Am. Inst. Metals* 11, 83(1917).—Stibnite is dissolved in NaOH or Na<sub>2</sub>S and Sb is deposited from this soln. in a high state of purity with a current efficiency of 76% and a voltage of 2.7. This makes the power cost about equal to that of electrolytic Zn production. After melting, the Sb was found to be very pure, containing only 0.02% S and 0.01% As, no Pb and a trace of Fe. A 5000-amp. plant was successfully experimented with. The soln. must be regenerated or renewed when one lb. of Sb is produced per lb. of NaOH used.

W. E. RUDER.

**A permanganate electric cell.** ARTHUR W. WARRINGTON. *Chem. News* 117, 97-8(1918).—HMnO<sub>4</sub> is a stronger oxidizing agent than chromic acid. Hence a cell with the former as depolarizer should be more active than one with the latter. Since ions will be relatively more plentiful in a dil. soln. than in a strong one, there is no adequate reason for using strong solns. Zn-C cells with 3.16 g. KMnO<sub>4</sub> + 6 cc. concd. H<sub>2</sub>SO<sub>4</sub> in a vol. of 250 cc. in the C-compartment and 14.55 g. crystd. ZnSO<sub>4</sub> in a vol. of 700 cc. in the Zn-compartment, gave a much better yield of elec. current than dichromate cells with which they were compared. The yield of current in a KMnO<sub>4</sub>-cell becomes very high when the solns. used are very dil.

LOUIS JORDAN.

**War-time development of vacuum tubes.** R. BROWN. *Elec. World* 73, 358-63 (1919).—The Signal Corps work in standardizing the various types of vacuum tubes for wireless transmission and receiving are described and curves of their characteristics given. The De Forest, General Electric and Western Electric types were used extensively. The design of tubes is to-day in advance of their practical application. The possibility of economically manufacturing tubes of desired characteristics in large quantities has been demonstrated.

W. E. RUDER.

**The development of the vacuum valve.** ANON. *J. Elec.* 42, 20-2(1919).—The method of manuf. of the Moorehead type of vacuum tube detector is briefly described. Photographs of some of the operations are given.

W. E. RUDER.

**The manufacture of vacuum detectors.** O. B. MOORHEAD. *Electrician* 87, 741

(1918).—A short description of the methods employed in assembling, exhausting and testing this type of wireless detector. W. E. RUDER.

Note on the effect of temperature on the resistances of spark plug insulations. J. D. MORGAN. *Engineering* 106, 513(1918).—Thirteen spark plugs from different makers were tested on heating to 500° in a small muffle and varying rates of sparking. Curves of results are given. Insulation leakage due solely to temp. is not so serious as the temp.-resistance curves indicate. Leakages at high temps. in some plugs was found to be excessive. At 400° the plugs varied in resistance from  $10^6$  to  $70 \times 10^6$  ohms. W. E. RUDER.

Transformer for welding battery connections. ANON. *Elec. World* 73, 608 (1919).—In order to afford convenient means for burning or welding straps and posts on storage batteries a small lead-burning transformer has been developed, designed on the arc-welding principle. It is to be connected directly to the 60-cycle 110-volt lighting circuit. When in operation the energy consumption is from 500 to 600 watts. Wt. of transformer is 25 lbs. C. G. F.

The testing of switch and transformer oils. C. SCHNEDELL. *Electrotechn. Z.* 25, (1918); *Electrician* 82, 125(1919).—In transformers, either resinous or mineral oils may be used. The resinous oils are better insulators and deposit very little material after long heating, but are slightly more volatile than mineral oils. They are unsuitable for switches, however, as they carbonize badly in the arc, leading to the possibility of explosions in oil switches. The oil must be free from cloudiness, straw, fiber, or sand. The  $d_{44}$  should be between 0.85 and 0.92 for transformers and 0.88–0.9 for switches. The flash-point should not be under 160° for transformers and 170° for switches. The Marcusson app. is recommended for this test. The test for the deposition of solid material by long heating is important and is described at length. The acidity and S tests are also described fully. W. E. RUDER.

Compact oil-testing cup. ANON. *Elec. World* 73, 348(1919).—A molded cup containing two brass electrode brushings is used for the test. Binding posts are attached to the accurately fitting electrodes which, by means of a steel feeder gage, can be set at exactly 0.1 in. (0.25 cm.). A 4-oz. sample of oil is tested for dielec. strength. The max. voltage required for reliable testing is given as 25,000 v. The whole cup weighs  $6\frac{1}{2}$  lbs. (2.9 kg.) and is  $21.6 \times 10 \times 12$  cm. overall. W. E. RUDER.

Certain characteristics of porcelain (BLEININGER) 19. Production of nitrogen compounds (MONTGOMERY) 18. Photometer liquids in tablet form (HAUSMANN) 1. Electric heating in concentration of sulfuric acid (PAGLIANI) 18. Valuation of natural and artificial bitumens for insulating cables (DUPRÉ) 22. The velocity of oxidation of nitric oxide (BRINER) 6. Photographic study of porcelain insulators (TUFTY) 19.

Storage battery. H. C. BUSCH. U. S. 1,292,247, Jan. 21. Structural features.

Electrolytic cell. E. E. NISWONGER and P. McDORMAN. U. S. 1,292,024, Jan. 21. The cell is adapted for producing relatively small amts. of NaOCl for use as an antiseptic in hospitals and is adapted to operate efficiently on less than 25 amps. of current under usual voltages. The cell is formed of hard rubber with electrodes of graphite.

Electric dry cell battery. N. K. CHANEY. U. S. 1,292,254, Jan. 21. In forming a mixt. for use in dry cells, C is employed which is free from ferrous sulfides. The exclusion of the latter serves to decrease corrosion of the Zn during the "shelf life" of the battery.

**Dry cell electric battery.** C. HAMBURCHEN. U. S. 1,292,764, Jan. 28. Dry cells are formed with a gelatinous electrolyte containing  $\text{NH}_4\text{Cl}$  450 g. to each 1000 cc. of 32%  $\text{ZnCl}_2$  soln.

**Electroplating apparatus.** J. GIULIANA. U. S. 1,291,830, Jan. 21.

**Alkali metal permanganates.** T. J. BREWSTER. U. S. 1,291,751, Jan. 21.  $\text{KCl}$  10 is dissolved in  $\text{H}_2\text{O}$  30 parts and if Ca compds. are present they are removed by pptn. with  $\text{K}_2\text{CO}_3$ . This soln. is then electrolyzed to produce  $\text{Cl}$ ,  $\text{KOH}$  and  $\text{H}$ . The  $\text{KOH}$  soln. drawn off from the electrolytic cell may be composed of  $\text{KOH}$  6,  $\text{KCl}$  2 and  $\text{H}_2\text{O}$  30 parts. This soln. may then be evapd. until it contains only 6 parts of  $\text{H}_2\text{O}$ , to effect the crystn. of the  $\text{KCl}$ , which is returned to the electrolytic cell. The strong  $\text{KOH}$  soln. obtained is mixed with 9 parts of finely ground oxides of  $\text{Mn}$  for each 6 parts  $\text{KOH}$  in the soln. and this mixt. is then heated in the air for 1-4 hrs. at a temp. of  $360-450^\circ$  to effect formation of  $\text{K}_2\text{MnO}_4$ . The calcined product is cooled, treated with  $\text{H}_2\text{O}$  and the soln. is then treated with  $\text{Cl}$  in excess to produce  $\text{KMnO}_4$  and  $\text{KClO}_3$ , which may then be sepd. from each other and from  $\text{KCl}$  in the soln. by fractional crystn. If it is desired to avoid the formation of chlorate, a restricted amt. of  $\text{Cl}$  is passed into a soln. containing  $\text{K}_2\text{MnO}_4$  and  $\text{KOH}$  to form hypochlorite and permanganate and there is then added to the soln. containing these products sufficient  $\text{HCl}$  to effect neutralization and conversion of unoxidized manganate into permanganate without formation of chlorate.  $\text{NaCl}$  may be similarly employed as a starting material, with formation of  $\text{NaMnO}_4$ . If desired  $\text{KOH}$  may be used as the starting material instead of  $\text{KCl}$  and a 5-10% soln. of the  $\text{K}_2\text{MnO}_4$  produced is boiled to produce  $\text{KMnO}_4$  and regenerate a portion of the  $\text{KOH}$ . The  $\text{K}_2\text{MnO}_4$  may also be oxidized to  $\text{KMnO}_4$  electrolytically, using a graphite anode and  $\text{Fe}$  cathode and a low current d. at the anode.

**Calcium carbide.** F. M. BECKET. U. S. 1,292,386, Jan. 21. Aggregates for use in the elec. furnace in the manuf. of  $\text{CaC}_2$  are prepd. from lime 100 and bituminous coal 100-110 parts, preferably using coal containing 30-36% volatile matter. The aggregate may be produced by burning lime and coking coal together in an inclined rotary tubular furnace, the temp. at the discharge end of which may be about  $1000^\circ$ .

**Calcium carbide.** F. M. BECKET. U. S. 1,292,387, Jan. 21. Aggregates for use in the manuf. of  $\text{CaC}_2$  are prepd. by heating a mixt. of limestone with about 62% its weight of a rich bituminous coal, first to a coking temp. and then to a lime-burning temp. The heating may be carried out as a continuous operation by passing the material on a conveyor or by other suitable arrangement through a furnace which is heated near its exit end to about  $1100^\circ$ .

**Calcium cyanamide.** G. E. COX. U. S. 1,292,715, Jan. 28. In the formation of  $\text{CaCN}_2$  from  $\text{CaC}_2$  by the action of  $\text{N}$ , a slab of kieselguhr or other heat-insulating material is placed over the top of the charge during the conversion, to prevent loss of heat from the top and promote uniformity of the nitrification throughout the mass of  $\text{CaC}_2$ .

**Apparatus for effecting gas reactions and electrical precipitation of solid reaction products.** L. BRADLEY. U. S. 1,291,745, Jan. 21. The app. is arranged for the circulation of reaction gases (such as smelter gases containing  $\text{SO}_2$ ) in a closed cycle. At one point in the cycle a reagent such as  $\text{NH}_3$  is introduced to produce a non-gaseous reaction product such as  $\text{NH}_4\text{HSO}_4$  and the reaction product is then removed and collected by elec. pptn.

## 6. INORGANIC CHEMISTRY.

H. I. SCHLESINGER.

The syn-crystallization of potassium and ammonium nitrate at ordinary temperatures. CAILLART. *Bull. soc. franc. min.* 41, 21-30(1918).—The formation of mix-crystals of these salts has been studied in fusions, but C. has now detd. the equil. relations in aqueous solns. By varying the relative amts. in the solns. mixed crystals with the form of  $\text{KNO}_3$  and again with that of  $\text{NH}_4\text{NO}_3$  were obtained.

E. T. WHERRY.

A contribution to the chemistry of tellurium sulfide. AARON M. HAGEMAN. *J. Am. Chem. Soc.* 41, 329-41(1919).—The introduction of  $\text{H}_2\text{S}$  into an aq. tetravalent Te soln. at room temp. ppts. a red-brown compd. represented by the formula  $\text{TeS}_2$ . Its production is independent of the acid concn. Below  $-20^\circ$   $\text{TeS}_2$  is stable, but above  $-20^\circ$  it dissociates, the dissociation being more rapid the higher the temp. The degree of dissociation at any one time or temp. can be detd. by the amt. of S which can be extd. by  $\text{CS}_2$ . Dissociation never continues to completion. The dissociated mass extd. with  $\text{CS}_2$  always retains at least 0.95% S. This S does not exist as a sulfide of Te that is decompd. by  $\text{HCl}$  or  $\text{HBr}$ , nor as a variety of S that is insol. in  $\text{CS}_2$ .  $\text{TeS}$  does not exist.  $\text{TeS}_2$  is pptd. by  $\text{H}_2\text{S}$  from org. solvents exactly as from aq. solns. Its stability is solely a question of temp.

R. H. LOMBARD.

The preparation of selenic acid. H. H. MORRIS. *Trans. Wis. Acad. Sci. Arts and Letters* 19, 369-73(1918).—M. recommends the method of Thomsen (*Ber.* 2, 598 (1869)), but suggests precautions necessary for obtaining a stable prepn. Carefully purified  $\text{SeO}_2$  is converted into  $\text{Ag}_2\text{SeO}_3$ , which is treated in aq. soln. with pure Br (free from reducing substances). The filtrate from the  $\text{AgBr}$  is concd. under reduced pressure to remove excess Br and  $\text{H}_2\text{O}$  in an all-glass app. The concd. acid is treated with well washed  $\text{H}_2\text{S}$  to remove  $\text{H}_2\text{SeO}_3$ . The ppt. of S and Se is removed by filtering through asbestos. Great care must be taken to exclude dust throughout the prepn.

A. L. BARKER.

Some properties of magnesium ammonium phosphate and magnesium pyrophosphate. Z. KARAOGLANOW AND P. DIMITROW. *Z. anal. Chem.* 57, 353-71(1918); *J. Soc. Chem. Ind.* 38, 40A.—The conversion of  $\text{MgNH}_4\text{PO}_4$  into  $\text{Mg}_2\text{P}_2\text{O}_7$  may or may not be accompanied by incandescence, depending upon the conditions under which the  $\text{MgNH}_4\text{PO}_4$  is pptd. The product will not incandesce if pptd. slowly at the boil, but will do so if formed quickly or at lower temps. It has been found that incandescence never takes place if all traces of org. matter are carefully excluded from the ppt. The properties of  $\text{Mg}_2\text{P}_2\text{O}_7$  depend upon whether it is formed with or without incandescence. If incandescence occurs, the product is hard and lava-like and gray to black in color, while if there is no incandescence, it is amorphous, loose in texture, and quite white.

E. J. C.

Formation of iron disulfide by a wet method. V. ROBR. *Mitt. kgl. Materialprüfungsamt.* 36, 93-107(1918); *J. Soc. Chem. Ind.* 37, 732A.—The  $\text{FeS}_2$  formed as the first product of the interaction of  $\text{H}_2\text{S}$  and iron hydroxide readily becomes partially insol. in  $\text{HCl}$ , as for example, when the reaction is carried out at a higher temp. The insol. substance has the compn.  $\text{FeS}_2$ ,  $d_4^{25}$  4.58, and is formed in accordance with the equation  $\text{Fe}_2\text{S}_3 \rightarrow \text{FeS}_2 + \text{FeS}$ . It may also be produced by the addition of S to  $\text{FeS}$ , in the absence of substances with an alk. reaction, which also interfere with its formation from  $\text{Fe}_2\text{S}_3$ . It is probably formed in this way in soils contg. iron hydroxide and putrescent matter, but free from alk.-earth carbonates. By boiling solns. of Fe with alkali polysulfides it may be found possible to sep. Fe quantitatively in the form of  $\text{FeS}_2$ .

E. J. C.

**Recovery of molybdenum as ammonium molybdate from residues.** S. MALOWAN. *Chem. Ztg.* 42, 410(1918); *J. Soc. Chem. Ind.* 37, 673A.—To recover molybdic acid used as a precipitant in P detns., ppt. the liquors with Na or Ca phosphate; after washing and drying the yellow ppt., heat with excess of strong  $\text{H}_2\text{SO}_4$  until soln. is complete, and the acid colorless. Pour the cold liquid into 8–10 times its vol. of water and ppt. the Mo with excess of  $\text{K}_4\text{Fe}(\text{CN})_6$ . Filter off the ppt. after 3 hrs. and wash with dil. ferrocyanide soln. till free from  $\text{H}_2\text{SO}_4$ ; then dry it, sep. from the filter, and ignite at a dark red heat to incipient fusion. Leach the cold mass twice with hot water, after which ext. the molybdic acid with  $\text{NH}_3$ . Filter the colorless soln. and evap. to dryness. Treat with a little water and  $\text{H}_2\text{O}_2$  and boil the soln. to oxidize any lower oxides. Dil. the resulting soln. of  $\text{NH}_4$  molybdate to a sp. gr. of 1.09 at  $17^\circ$  (i. e., 10%).

**Studies on sulfites, thiosulfates, and polythionates.** A. SANDER. *Z. angew. Chem.* 31, I, 197(1918); *J. Soc. Chem. Ind.* 37, 731A.—In connection with his work on the quant. detn. of sulfites, thiosulfates, and polythionates (*C. A.* 9, 279, 2042; 10, 866, 1140), S. has studied the action of these substances on  $\text{HgCl}_2$ . By the interaction of  $\text{HgCl}_2$  with alkali thiosulfates and polythionates, very unstable Hg thiosulfates and polythionates are formed, which immediately break down into  $\text{HgS}$  and free  $\text{H}_2\text{SO}_4$  (together with free S in the case of tetra- or pentathionates). Alkali sulfites and bisulfites, on the other hand, form with  $\text{HgCl}_2$  stable complex compds., salts of the disulfonic acid,  $\text{Hg}(\text{SO}_3\text{H})_2$ , and of the chlorosulfonic acid,  $\text{HgClSO}_3\text{H}$ . The quant. analytical processes worked out by S. depend upon this difference in behavior towards  $\text{HgCl}_2$ .

E. J. C.

**The velocity of oxidation of nitric oxide in reference to the industrial problem of the oxidation ("recuperation") of the oxides of nitrogen.** E. BRINER. *Arch. sci.* 46, Supplement, 23–5(1918); *Sci. Abstracts* 21A, 398(1918).—B. has studied the conditions affecting the oxidation of NO, formed in the arc discharge through air. In excess of O, the reaction is bimol., the velocity coeff. at  $21.5^\circ$  being about 0.051. With change of temp., this will vary according to the conditions of heat radiation; under the particular conditions of B.'s expts., lowering the temp. by  $10^\circ$  between  $6^\circ$  and  $50^\circ$  increased the oxidation by 10–20%, due probably to the fact that lowering the temp. favors the production of  $\text{N}_2\text{O}_4$  and  $\text{N}_2\text{O}_3$  mols.

## 7. ANALYTICAL CHEMISTRY.

E. G. R. ARDAGH.

**Notes on chemical standards and their bearing on the unification of analysis.** C. H. RIDSDALE AND N. D. RIDSDALE. *J. Soc. Chem. Ind.* 38, 15–267(1919).—A review and discussion of the subject in general, together with views based on the authors' experience in the prepn. and issue of private standards (5 basic and 5 acid steels, 1 cast Fe, and 1 hematite). Tables are given showing (1) the relative accuracy of analytical methods as indicated by the extremes of variation obtained between a no. of chemists (using normal care) on standardized steels; (2) final results after investigation, representing work with extreme care. Analytical methods with recom-

recommendations and precautions are given in an appendix. At the present time, the Iron and Steel Inst. has in progress the prepn. of analytical steel standards. Cf. Hillebrand, *C. A.* 11, 426.

F. W. SMITHER.

Calculation of the error made in volumetric analysis. V. ZOTTER. *Bull. sci. pharmacol.* 25, 357-64(1918).—Continuation of an earlier paper. Cf. *C. A.* 13, 403.

F. S. HAMMETT.

Errors in alkalimetry due to the carbon dioxide content of distilled water. G. BRUHNS. *Z. anal. Chem.* 57, 257-77(1918); *J. Soc. Chem. Ind.* 37, 750A.—Distd. water absorbs  $\text{CO}_2$  from the atin. and this dissolved  $\text{CO}_2$  has a marked influence on the results obtained in alkalimetric titrations if such water is used for the prepn. of the standard solns. The standard acid and alkali solns. themselves absorb  $\text{CO}_2$ .

E. J. C.

A titration formula. F. K. STEPHAN. Amsterdam. *Chem. Weekblad* 16, 44-6 (1919).—Volumetric calcns. can be simplified by the use of the formula:  $NVE = P$ , where  $N$  is the normality of the soln.,  $V$  is the number of l. taken as a standard,  $P$  is the wt. in g. of the dissolved substance, and  $E$  is 1 g.-equiv. of the same.

JULIAN F. SMITH.

Arsenious acid as a standard substance in iodometry. ROBERT M. CHAPIN. *J. Am. Chem. Soc.* 41, 351-8(1919).—The work indicates that arsenious acid properly prepared is a very satisfactory standard material in iodometry. L. J. ROGERS.

Zinc dust for analysis. O. BINDER. *Chem. Zig.* 42, 458(1918); *J. Soc. Chem. Ind.* 37, 718A.—B. has found that Zn dust contains appreciable amts. of Cl, for which allowance must be made in certain analytical processes.

E. J. C.

Utilization of waste paper in filtration. S. L. JODIDI AND H. G. HIGGINS. *Chem. Eng.* 27, 45-60(1919); cf. *C. A.* 10, 730, 1146, 1620, 1970.—The authors report in detail a series of expts. on the detn. of Ca, Mg, Ag and  $\text{P}_2\text{O}_5$ , using pulp filters made of S. and S. No. 588 paper filters, and (treated and untreated) "Westowl" paper towels, "Scottissue" paper towels, blotting paper, used newspaper, and used writing paper. Those kinds of paper which pulp readily can ordinarily be used in pulp form for filtration purposes. The various pulp filters described are not recommended in preference to pulp filters made from quantitative filters, but are recommended whenever standard filter paper is not available, especially for technical and com. work.

F. W. SMITHER.

Bibliography on the analysis of antimony. I. ELTON R. DARLING. *Chem. Eng.* 27, 11-2, 21, 63(1919).

E. H.

Determination of antimony in white metal. E. W. KAISER. *Metall* 1917, 320-1; *Z. angew. Chem.* 31, II, 230(1918); *J. Soc. Chem. Ind.* 37, 627A.—One g. of drillings is dissolved in 20 cc. of concd.  $\text{H}_2\text{SO}_4$ , cooled, and dild. with 50 cc. of water. Fifteen cc. of concd. HCl is added and the soln. boiled till all odor of Cl has disappeared. 100 cc. of water is added when cold and 15 cc. of a soln. contg. per l. 67 g. of  $\text{MnSO}_4$ , 135 cc. of  $\text{H}_3\text{PO}_4$  (sp. gr. 1.7), and 130 cc. of concd.  $\text{H}_2\text{SO}_4$ . The mixt. is titrated with 0.1  $N$   $\text{KMnO}_4$  standardized against pure Sb powder. If Sn and Cu are present ( $\% \text{Sn} \times 0.4 + \% \text{Cu}$ ) + 100 cc. is deducted from the result of the titration. Arsenic may be subtracted directly. If more than 0.3% Fe is present the preliminary soln. must be made in HCl and  $\text{KClO}_3$  and the Sb pptd. from the dild. soln. by an Fe rod, filtered off, and treated as above. For the estn. of Sn the Sb is pptd. and filtered off through a filter strewn with Fe filings.  $\text{CO}_2$  is passed through the filtrate, which is titrated with I and starch.

E. J. C.

Determination of molybdenum. K. WOLF. *Z. angew. Chem.* 31, I, 140(1918); *J. Soc. Chem. Ind.* 37, 561A.—The conversion of a ppt. of Mo sulfide into  $\text{MoO}_3$  by igni-

tion is not quant. if the temp. rises above  $450^{\circ}$ , as sublimation then occurs to an appreciable extent. A temp. of  $400^{\circ}$  suffices and it is most convenient and certain to ignite the ppt. in an electrically heated furnace at a temp. of  $425^{\circ}$ . E. J. C.

**Determination of lead in ores, etc.** W. STAHL. *Chem. Ztg.* 42, 317(1918); *J. Soc. Chem. Ind.* 37, 548A.—A weighed quantity of the finely divided sample is mixed with about 500 cc. of water, acidified with  $\text{HNO}_3$ , and heated at  $40^{\circ}$  for 2 hrs. The mixt. is then dild. with water, treated with  $\text{H}_2\text{S}$ , filtered, and the insol. portion washed with warm water contg. a small quantity of K sulfide. The insol. portion is then heated with  $\text{HNO}_3$  until all S has been oxidized, the soln. evapd. with the addition of  $\text{H}_2\text{SO}_4$  and the  $\text{PbSO}_4$ , etc., collected and washed with dil.  $\text{H}_2\text{SO}_4$ . The ppt. is then extd. with warm ammoniacal  $\text{NH}_4$  tartrate soln., filtered, and the insol. portion washed with warm water. The filtrate now contains the  $\text{PbSO}_4$  together with Sb; the Sb remains in soln. when the filtrate is acidified with  $\text{H}_2\text{SO}_4$  and mixed with alc., while the  $\text{PbSO}_4$  is re-pptd. and is collected, dried, and weighed. E. J. C.

**Volumetric determination of lead in tin-plate.** J. DEININGER. *Z. Nahr. Genussm.* 36, 66-7(1918); *J. Soc. Chem. Ind.* 37, 736-7A.—Heat about 0.5 g. of the metal with 10 cc. of concd.  $\text{H}_2\text{SO}_4$  until metallic particles are no longer visible; after cooling add 20 cc. of 5%  $\text{NH}_4$  oxalate and again heat the mixt. in order to dissolve remaining traces of Fe. Then add alc., collect the  $\text{PbSO}_4$ , wash with dil. alc., then dissolve in 15 cc. of hot 50%  $\text{AcONa}$  soln., and add Br water, drop by drop, to the warm soln. until a slight excess is present. After 5 min., collect the pptd.  $\text{PbO}_2$ , wash with hot water, rinse into a beaker with cold satd.  $\text{AcONa}$  soln., and treat with 20 cc. of 5% KI soln. and 10 drops of  $\text{AcOH}$ . The  $\text{PbO}_2$  decomposes rapidly; titrate the liberated I with  $\text{Na}_2\text{S}_2\text{O}_3$  soln. Each cc. of 0.1 N  $\text{Na}_2\text{S}_2\text{O}_3$  soln. is equiv. to 0.01036 g. Pb. The  $\text{PbSO}_4$  obtained by the treatment with  $\text{H}_2\text{SO}_4$  contains Sn, and if weighed directly the results obtained are much too high. E. J. C.

**Gravimetric determination of copper by means of sodium nitroprusside, and the separation of copper from mercury.** E. VOTOCERK AND J. PAZOUERK. *Chem. Ztg.* 42, 475-6(1918); *J. Soc. Chem. Ind.* 37, 751A.—Mix a cupric salt with an excess of Na nitroprusside soln. acidified with dil.  $\text{H}_2\text{SO}_4$ , dil. the mixt. to 170 cc., and shake for 2 to 4 hrs.; then collect the pptd. cupric nitroprusside on a tared filter, wash with water, dry at  $110^{\circ}$ , and weigh; it contains 22.75% Cu. The yield averages 99.2% of the amt. of Cu present. To det. Cu in the presence of Hg, ppt. the Cu as cupric nitroprusside as described, but in this case also add a known excess of 0.1 N NaCl soln. to prevent pptn. of mercuric nitroprusside. Then ppt. the Hg in the filtrate from the Cu ppt. as sulfide or det. by titrating the excess of NaCl with standard Hg soln. The presence of Pb and Bi does not interfere with the detn. of Cu, but Sn salts should not be present. E. J. C.

**Determination of copper by means of potassium thiocyanate and potassium iodide.** G. BRUHNS. *Centralbl. Zuckerind.* 26, 354-6(1918); *Z. angew. Chem.* 31, II, 310; *J. Soc. Chem. Ind.* 37, 751A.—In the estn. of Cu in Fehling soln., by means of KCNS and KI, by the method previously described (cf. C. A. 12, 2293), considerable errors may occur if the acidified Cu soln. is allowed to stand for some time after the addition of KCNS before being titrated with thiosulfate soln. These errors are due to the gradual formation of insol. CuCNS, the Cu thus pptd. being removed from the iodometric estn. E. J. C.

**Determination of tungsten and vanadium in the presence of titanium.** G. FENNER. *Chem. Ztg.* 42, 403(1918); *J. Soc. Chem. Ind.* 37, 609A.—When a mineral, etc., contg. W and Ti is fused with  $\text{Na}_2\text{O}_2$ , the melt then treated with water, boiled for a few mins., and filtered, the Ti remains insol. in the Fe ppt. while the W is completely

sol. and is found in the filtrate. V, if present in small quantity (less than 0.5%), remains almost entirely insol., but in larger quantity a portion is found in the filtrate. To det. V in the presence of Ti treat the mineral with HF and  $\text{H}_2\text{SO}_4$  to remove silica, then fuse the residue with  $\text{Na}_2\text{S}_2\text{O}_7$ , dissolve the melt in dil.  $\text{H}_2\text{SO}_4$ , filter the soln., and treat the filtrate with  $\text{H}_2\text{O}_2$  until a distinct yellow coloration has developed, a large excess of peroxide being avoided. Then add  $\text{NH}_4\text{F}$  or HF, whereby the yellow color of the Ti compd. is destroyed, while the red-brown coloration of the V compd. remains unaffected. Add  $\text{H}_3\text{PO}_4$  to remove color due to Fe salts, and det. the V colorimetrically by comparison with a standard prepd. with the same quantities of reagents.

E. J. C.

Simplification and modification of my process of determining phosphorus in pig iron and determination of silica. A. CAVAZZI. *Ann. chim. applicata* 10, 137-49 (1918); cf. C. A. 11, 3192.—The method is as follows: Take 5 g. of the reduced and powdered material, wash well with  $\text{Et}_2\text{O}$  to remove fatty substances, place in a 600 cc. beaker, and add at once 60 cc. 1:1  $\text{HNO}_3$ , immediately covering the vessel with a watch glass. Allow to dissolve, starting soln. with slight warming if necessary. When nitrous vapors cease coming off heat carefully and keep at slight ebullition till the yellow-red nitrous vapors disappear under the watch glass. Pour the liquid into a porcelain dish of 20 cm. diam., together with the rinsings made by warm  $\text{H}_2\text{O}$  slightly acidulated with  $\text{HNO}_3$ . Add 9 cc. concd.  $\text{H}_2\text{SO}_4$  and heat the dish on a gauze with ring burner to light boiling of the soln. and keep so, agitating lightly only on the bottom of the dish. This agitation may be omitted with very dense and viscous solns. of  $\text{Fe}_2(\text{SO}_4)_3$ . After continued careful concn., white fumes of free  $\text{H}_2\text{SO}_4$  appear. Increase the heat, but not so much as to cause the gauze to take on more than an incipient red color. Continue till no more white fumes are seen and the mass becomes friable and grayish yellow. Allow to cool, loosen the crust adhering to the walls of the dish and pulverize finely in the same dish with a glass pestle. Heat again, stirring the powder from time to time to drive out all the free  $\text{H}_2\text{SO}_4$ . Place the powder in a 150-cc. beaker, add about 10 cc.  $\text{H}_2\text{O}$  that has been used to wash out the porcelain dish, using a policeman or rubber glove on the index finger, add 40 cc.  $\text{H}_2\text{O}$  and 10 cc. concd.  $\text{HNO}_3$ . (On this matter of addn. of  $\text{HNO}_3$ , C. mentions the following expt.: Taking 20 cc. of a boiling soln. containing 3 g.  $\text{Fe}_2(\text{SO}_4)_3$ , 1 cc. concd.  $\text{HNO}_3$ , 0.0173 g. crystd.  $\text{Na}_2\text{HPO}_4$  and 3 g.  $\text{NH}_4\text{NO}_3$ , i. e., a soln. comparable to that obtained from 1 g. cast Fe with 0.15% P, he added rapidly 20 cc. of a boiling soln. containing 0.6 g.  $\text{NH}_4$  molybdate, keeping the temp. at about  $80^\circ$ . The soln. remained limpid even after 10 min. agitation. He then added another cc. concd.  $\text{HNO}_3$ . After 2 min. and even less of agitation, the liquid began to cloud and the yellow ppt. of phosphomolybdate deposited increasingly rapidly.) Place a flask of cold water so that the spherical surface rests over the mouth of the beaker, and close up the opening at the lip of the beaker by inserting a glass rod into it. Heat over a metal gauze to light boiling and keep so for 30-45 min. Every 10-15 min. replace the flask by another, also containing cold water. The  $\text{Fe}_2(\text{SO}_4)_3$  is now completely dissolved. Allow the liquid to cool, pour into a 9 cm. smooth filter, wash the  $\text{SiO}_2$  and C upon the filter 6 times with boiling  $\text{H}_2\text{O}$  slightly acidulated with some drops of  $\text{HNO}_3$ . To cut down the time of filtration make use of a suction flask and moderate aspiration, putting the point of the filter in a Pt cone. (C. describes a simple aspirator designed to avoid danger of rupturing the filter.) Transfer the filtrate to a 300-cc. beaker together with the washings. Add 15 g. solid crystd.  $\text{NH}_4\text{NO}_3$ , heat, and when the liquid begins to boil add rapidly and at once 40 cc. of a boiling soln. containing 5 g.  $\text{NH}_4$  molybdate, agitating immediately and vigorously continuing for some minutes. Maintain the liquid at  $70$ - $80^\circ$  for 30 min. This warming favors the formation of the  $\text{NH}_4$  phosphomolybdate and is especially necessary when small

amounts of  $\text{H}_2\text{PO}_4$  are present. Allow to cool, filter on a 7-cm. filter, wash the ppt. by decantation with a boiling soln. of  $\text{NH}_4\text{NO}_3$  (25 g. of the latter with 20 cc. 1.153  $\text{HNO}_3$  in 500 cc.  $\text{H}_2\text{O}$ ). Carry out the decantation washing by adding 20 cc. of the boiling acid soln. to the ppt. in the beaker, agitating for 1 min. with a rod, allowing the liquid to rest for 2 min. and pouring the clear soln. upon the filter. Repeat 4 times. Discard the filtrate. Dissolve the slight amt. of ppt. on the filter with 1:3  $\text{NH}_4\text{OH}$ , wash 5 or 6 times with  $\text{H}_2\text{O}$ , collecting the whole in the beaker containing the major part of the phosphomolybdate. Dissolve this in the ammoniacal liquid by agitation. It is advisable to reprecipitate, in order to purify from possible presence of Fe. The same object may be secured in the following way: Add at once to the cold ammoniacal soln. of the phosphomolybdate 3 g.  $\text{NaCl}$ , bring to boiling, and keep boiling for 10 min. in order to drive out a certain part of the free  $\text{NH}_3$ . Under these conditions, and especially because of the presence of  $\text{NaCl}$ , the Fe remaining in the phosphomolybdate seps. completely as  $\text{FePO}_4$ . Filter on a 5.5 cm. filter, keeping the soln. very warm, wash the ppt. 6 times with a boiling soln. of 1 g.  $\text{NaCl}$  in 50 cc.  $\text{H}_2\text{O}$ . Place the still moist filter with ppt. into a Pt crucible and ignite. Drop the red ashes into a small mortar, mix ultimately with about 0.3 g.  $\text{NaKCO}_3$  and a little  $\text{KNO}_3$ . Fuse, stopping the heating when the development of bubbles has ceased. Cool. Add 6 portions of 3 cc. each of boiling  $\text{H}_2\text{O}$ , filter on a 4-cm. filter into a small beaker. Add a few drops of  $\text{HNO}_3$  to strong acid reaction, boil for 10 min., neutralize with  $\text{NH}_4\text{OH}$  to strong odor, and add the liquid to the soln. previously sepd. from the  $\text{FePO}_4$ . Now add 3 g. solid  $\text{NH}_4\text{Cl}$ , bring to boil, then pour into it  $\frac{1}{4}$  of its vol. of concd.  $\text{NH}_4\text{OH}$  and add from a buret while agitating the liquid without interruption 10 to 20 cc. non-acid magnesia mixt. (55 g. crystd.  $\text{MgCl}_2$  + 105  $\text{NH}_4\text{Cl}$  in a l.  $\text{H}_2\text{O}$ ). Continue agitation for a few min., allow to cool for not less than  $\frac{1}{2}$  hr. and filter on a 5.5 cm. filter. Wash the  $\text{NH}_4\text{-MgPO}_4$  15 times with 1:4  $\text{NH}_4\text{OH}$ , dry, filter and ppt. for 1 hr. at  $100^\circ$ , sep. ppt. from filter, incinerate the latter in a weighed Pt crucible, moisten the generally black residue with 3 drops concd.  $\text{HNO}_3$ , evap. gently to dryness, ignite over the blast to whiteness. Cool, add the sepd. ppt., heat for at least 15 min. at a dark red heat with crucible covered. Cool, add 5-6 drops concd.  $\text{HNO}_3$ , evap. gently and carefully. Heat strongly over the blast for at least 5 min. and weigh as pyrophosphate. C. confirmed the simplicity, certainty and accuracy of the method by many analyses. He makes the following suggestions to assure complete pptn. of the phosphomolybdate, and at the same time avoid the use of large quantities of molybdate soln. in analyzing cast irons where the content in P is approx. known. Prep. the  $\text{HNO}_3$  soln. of the  $\text{Fe}_2(\text{SO}_4)_3$  for 6 g. alloy instead of for 5 g. Bring the soln. to exactly 180 cc. by addn. of  $\text{H}_2\text{O}$ . Call this the "final soln." Take 30 cc. of this and if the P content is 0.15% or less add to it at the boiling temp. 0.75 g. dry molybdate dissolved in about 20 cc.  $\text{H}_2\text{O}$ . Keep for 15 min. at  $70-80^\circ$  stirring with a rod. If the pptn. is complete ppt. the remaining 150 cc. of the "final soln.," corresponding to 5 g. alloy, with 4 g. molybdate dissolved in 30 cc.  $\text{H}_2\text{O}$ . Of course the phosphomolybdate formed in the 30 cc. portion of the "final soln." is discarded. For alloys containing about 0.3% P makes the test on 30 cc. of the "final soln." as before, allow to cool and the phosphomolybdate to settle, filter the supernatant liquid on a 7-cm. filter without washing. After each new addn. of molybdate repeat these operations. The successive addn. of molybdate, after the first of 0.75 g., are 0.1, 0.05 and 0.05. In the 3 final addns. the molybdate is dissolved in smaller portions of  $\text{H}_2\text{O}$ . There is obtained with the last portion a soln. which does not become turbid with further addn. of the reagent after maintaining for 15 min. at  $70-80^\circ$  and stirring. In that case treat the balance of the "final soln." with 5 g. molybdate in 40 cc.  $\text{H}_2\text{O}$ . With alloys containing 0.5% P, the preceding procedure is followed out, using 4 successive portions of molybdate after the first of

0.75 g.—*i. e.*, 0.1, 0.1, 0.05, 0.05. If the final portion completes the pptn. of the phosphomolybdate, use 120 cc. of the "final soln." for the actual analysis, treating it with 5 g. molybdate in 40 cc.  $H_2O$ . Where the P content is between 0.5 and 3.0%, the successive addns. of molybdate in the 30-cc. test soln. become too numerous and complicated. A better way is as follows: Take a 30-cc. portion as before, add 8 cc. concd.  $HNO_3$  and 12 g.  $NH_4NO_3$ . Bring to boiling, pour into it at one time while stirring, a soln. of 5 g. molybdate in 50 cc.  $H_2O$ . If the ppt. is abundant continue the operation as in the full method, thus obtaining the  $Mg_3P_2O_7$ , corresponding to 1 g. cast Fe. If the phosphomolybdate is comparatively scant, agitate and bring the turbid liquid again to boiling and add another 30 cc. portion of the "final soln." Assure yourself that the molybdate is in excess by heating 20 cc. of the clear liquid with 0.05 g. molybdate dissolved in a little  $H_2O$ . The  $Mg_3P_2O_7$  obtained will correspond to 2 g. cast Fe. C's method of detg.  $SiO_2$  and C is as follows: After having washed the residue of  $SiO_2$  and C as described in the previous method 6 times with  $H_2O$  acidulated with  $HNO_3$ , continue the washings with boiling  $H_2O$  made strongly acid with  $HNO_3$  and  $HCl$  to sep. from the  $SiO_2$  every trace of Fe compd. Dry the filter with residue in the oven, sep. the ppt. from the filter and burn the latter in a Pt crucible. Mix the little ash produced intimately with the material sepd. from the filter and weigh. Where 5 g. cast Fe have been taken take about  $\frac{1}{8}$  or  $\frac{1}{16}$  of the latter mixt., according as the metal is more or less rich in C and Si, *i. e.*, amounts corresponding to 1 or 2 g. cast Fe, ignite in a weighed Pt crucible over the blast lamp till the C disappears. The increase in wt. of the concn. equals the amt. of  $SiO_2$ , which multiplied by 0.46932, gives Si. If it is desired to det. only the amount of Si in a cast Fe, treat 1 or 2 g. of the metal in fine granules or shavings in a 400 cc. beaker with 30 or 40 cc. 1:1  $HNO_3$ . Carry out as in the full method, but to the  $HNO_3$  soln. evapg. in the porcelain dish add 2 cc. instead of 9 cc.  $H_2SO_4$ . After all the  $H_2SO_4$  has been driven out continue the baking of the residue of  $Fe_2(SO_4)_3$ ,  $SiO_2$  and graphitic C about  $\frac{1}{2}$  hr. longer than in the full method, then introduce it into a beaker with 50 cc. 1:9  $HNO_3$  with a little  $H_2O$  that has been used to wash the dish. Digest for 30 min., with a flask of cold water over the dish, renewed every 15 min. to serve as condenser. Cool, filter and wash on a 6-cm. filter 15 times with boiling  $H_2O$  made strongly acid with  $HNO_3$  using gentle aspiration if necessary to hasten filtration. Place moist filter in a covered and weighed Pt crucible. Heat moderately to carbonization of the filter and stopping of volatile vapors, remove lid from the crucible and ignite strongly over the blast. The  $SiO_2$  should be very white. With metals very poor in Si, make the detn. upon 4 or 5 g.

ROBERT S. POSMONTIER.

**Determination of white phosphorus in mouse poisons.** F. MACH AND B. LEDERLE. *Chem. Ztg.* 42, 491(1918); *J. Soc. Chem. Ind.* 37, 747A.—Ten g. of the material are mixed with 5 g. of plaster of Paris, the powdered mixt. is transferred to a 200-cc. cylinder and shaken for 1 hr. with 100 cc. of  $CS_2$ . After settling, 10 cc. of the clear soln. are withdrawn and added to 50 cc. of satd. Br soln. The oxidation of the P by the Br is complete in 1 hr. at the ordinary temp. and the resulting  $H_3PO_4$  is pptd. as  $MgNH_4PO_4$  after the  $CS_2$  and the excess of Br have been evapg.

E. J. C.

**Rapid method of reduction of potassium chloroplatinate.** HORSCH. *Compt. rend.* 168, 167-9(1919).—After washing with 80% alc., dissolve the moist ppt. of  $K_2PtCl_6$  in boiling  $H_2O$ , receiving the soln. in a weighed Pt crucible; add 2 or 3 cc. of alc. and heat on a boiling  $H_2O$  bath. After  $\frac{1}{2}$  to 1 min. a firmly adhering layer of metallic Pt deposits gradually and uniformly on the inner surface of the crucible. When reduction is complete (about 25 min.), add a few drops of alc. and let stand 5 min.; decant off the soln. and wash with  $H_2O$ , dry on the  $H_2O$  bath, and ignite strongly until the deposit assumes the color of the crucible. Complete reduction by alc. takes place only in the

presence of metallic Pt; HCHO reduces the  $K_2PtCl_6$  more slowly, yielding a less adherent deposit; allyl alc. produces no reduction, even in the presence of metallic Pt. The method is suggested as a procedure for repairing Pt ware. F. W. SMYTH.

**Determination of free and carbonated alkalis in alkaline solutions of hypochlorites.** M. PHILIBERT. *J. pharm. chim.* 18, 260-72(1918); cf. Mestrezat, *C. A.* 12, 1787, 2178.—(I) In detg. *total alkali* ( $A_t$ ), P. first removes the oxidizing agent (Cl or NaClO) by means of  $Na_2S_2O_3$ , not in alk. (Mestrezat) but in *acid* soln. (definite excess) in the presence of an excess of KI. This incidentally detg. the amt. of active Cl, and it causes a definite amt. of added acid to disappear:  $2 HCl + 2 KI + NaClO = NaCl + H_2O + 2 KCl + I_2$ . The remainder of the excess acid, P. detg. by the Kjeldahl use of  $KIO_3$  as follows:  $6HCl + KIO_3 + 5 KI = 6KCl + 3H_2O + 6I_2$ . In both cases, 1 equiv. of I indicates 1 equiv. of HCl. For Kjeldahl's soln., mix equal vols. of 0.5 g.  $KIO_3$  per 100 cc. and 3.0 g. KI per 100 cc. and decolorize with a few drops of  $Na_2S_2O_3$ . P. proceeds as follows: To 10 cc. of alk. NaClO soln. add 5 cc. of 20% KI and 30 cc. 0.1 N HCl or  $H_2SO_4$ , i. e., an excess of acid, and titrate I with 0.1 N  $Na_2S_2O_3$ . Now add 60 cc. of Kjeldahl mixt., which sets I free at once if HCl is in excess; titrate I with the same thio soln. The total vol. of  $Na_2S_2O_3$  subtracted from the total HCl used, gives cc. of 0.1 N total alkali.  $CO_2$  having a slight influence, a correction of 0.1 cc. for much carbonate present, and 0.2 cc. for  $NaHCO_3$  is subtracted from the vol. of  $Na_2S_2O_3$  consumed. (II) To det. *free* (a) *carbonated* (b) or *bicarbonated* (c) *alkali* ( $A_b$ ), ppt. b with  $BaCl_2$  if only a and b are present. In presence of c convert it into b by adding a definite excess of 0.1 N  $Ba(OH)_2$  soln. Proceed as follows: To 20 cc. NaClO soln. add excess of 0.1 N  $Ba(OH)_2$  soln., i. e., equal to twice the no. of cc. of total 0.1 N alkali found under (I), then 5 cc. of 20%  $BaCl_2$  soln., fill up to 100 cc. with  $CO_2$ -free  $H_2O$ , stir, allow to stand for 2 or 3 min., filter. Collect 50 cc. filtrate (= 10 cc. hypochlorite), then treat as under (I) for total alkali with KI, excess of HCl, then Kjeldahl soln. and det. total  $Na_2S_2O_3$  soln. Total alkali = total acid — ( $\frac{1}{2} Ba(OH)_2$  + total  $Na_2S_2O_3$ ). The resulting values are positive for total and free alkali, negative for bicarbonate. Five or 6 possibilities are considered: (1) Only free alkali is present; then  $A_b > 0$ ,  $A_t - A_b > 0$ .  $BaCl_2$  gives no ppt. (2) Free alkali ( $A_b$ ) and neutral carbonate ( $A_t - A_b$ ) are present. Then  $A_b > 0$ ,  $(A_t - A_b) > 0$ .  $BaCl_2$  ppts. only part of the alkali. (3) Only carbonate ( $A_t$ ) is present.  $A_b = 0$ .  $BaCl_2$  ppts. all alkali. (4) A mixt. of neutral carbonate ( $A_t - A_b$ ) and bicarbonate ( $A_b$ ) is present.  $A_b < 0$ ;  $(A_t - A_b) > 0$ .  $BaCl_2$  ppts. more alkali than the original liquid contained. (5) The soln. contains bicarbonate only. Then  $A_b < 0$ , and  $(A_t - A_b) = 0$ . Pptn. has taken away just twice as much alkali as the sample contained. (6) A possible excess of  $CO_2$  ( $A_b - A_t$ ) is present. In this case, more  $Ba(OH)_2$  must be added than previously.  $A_b = 0$ ;  $(A_t - A_b) < 0$ . The results of P.'s method, compared with those of Mestrezat, on 2 solns. of, resp.,  $Na_2CO_3$ , 10  $H_2O$  and  $KHCO_3$ , and an equal vol. mixt. thereof, and on Dakin's soln., are recorded in 4 tables. P. concludes: (1) Only when destruction of NaClO takes place in *acid* soln. in presence of KI, results in total alkali will be const. Results are uncertain in alk. soln., due to opposite reactions: Oxidation to  $Na_2SO_4$  and free acid if  $Na_2S_2O_3$  soln. is present in small amt.; or formation of  $Na_2S_4O_6$  and free NaOH by the action of NaClO if  $Na_2S_2O_3$  is in excess. (2) The only exact process for detg.  $CO_2$  in  $Na_2CO_3$  is the "classic" method with  $BaCl_2$ , although that of Mestrezat, with phenolphthalein and litmus, or as modified by P. with litmus alone, gives approx. results. (3) The iodate method described is simple and sufficiently exact, results varying only about 2%.

S. WALDBOTT.

**Source of error in the determination of sulfur in pyrite.** O. BINDER. *Chem. Ztg.* 42, 503(1918); *J. Soc. Chem. Ind.* 37, 730A.—To insure thorough mixing of the  $Na_2CO_3$  and  $KNO_3$  in prepg. a stock of fusion mixt., it is recommended that the  $Na_2CO_3$

be suitably colored and the mixing then continued until the color of the whole mixt. is uniform.

E. J. C.

**Analysis of scrap metals and dross, etc. Analysis of cement copper.** O. BINDER. *Chem. Ztg.* 42, 546(1918); *J. Soc. Chem. Ind.* 37, 770A.—Specimens of scrap metals or dross, etc., usually contain large pieces of metal more or less coated with oxide, and it is impossible to obtain a fair av. sample for analysis; it is recommended that, after finer portions of the sample have been sepd. by a sieve, the larger pieces should be melted together and then filed so as to obtain a portion for weighing. In the detn. of Cl in cement Cu, soln. of the sample in  $\text{HNO}_3$  brings about loss of Cl, and the Cu is not dissolved completely.

R. H.

**Determination of active oxygen in sodium peroxide.** J. MILBAUER. *J. prakt. Chem.* 98, 1-8(1918); *J. Soc. Chem. Ind.* 38, 10A.—Methods depending on the liberation of  $\text{H}_2\text{O}_2$  by water, followed by titration with  $\text{KMnO}_4$ , and on the treatment of  $\text{Na}_2\text{O}_2$  with KI and  $\text{KHCO}_3$  and titration of the liberated I with Na arsenite give low results, while measurement of the O liberated by water in the presence of  $\text{Co}(\text{NO}_3)_2$  gives high results. The following processes yield accurate results: (1) Water (100 cc.) is mixed with concd.  $\text{H}_2\text{SO}_4$  (5 cc.) and chemically pure  $\text{H}_3\text{BO}_3$  (5 g.);  $\text{Na}_2\text{O}_2$  (0.5 g.) is added gradually to the mixt. which is kept briskly shaken, and the liberated  $\text{H}_2\text{O}_2$  is titrated with  $\text{KMnO}_4$ . The low results given by the older permanganate method are to be attributed to the catalytic decompn. of a portion of the  $\text{H}_2\text{O}_2$  by the  $\text{MnSO}_4$  formed during the titration. (2)  $\text{Na}_2\text{O}_2$  is introduced gradually into a soln. of KI (2 g.) in dil.  $\text{H}_2\text{SO}_4$  (1 in 20; 200 cc.); the I is titrated with standard  $\text{Na}_2\text{S}_2\text{O}_3$ . The results agree with those obtained by the permanganate method. (3)  $\text{Na}_2\text{O}_2$  (0.2-0.3 g.) is mixed with about 10 cc. of Cu sulfate soln. (0.05%) in a small flask connected to a nitrometer; the flask is shaken, and decompn. is completed within a minute, when the liberated O is measured. The gas evolved contains about 0.32% of  $\text{CO}_2$  and 0.08% of H. With  $\text{Co}(\text{NO}_3)_2$  as catalyst, the results are invariably high; M. considers that this may indicate the presence of an oxide higher than the peroxide. The action of the atm. on  $\text{Na}_2\text{O}_2$  has also been investigated; moisture appears to be more active than  $\text{CO}_2$  in causing decompn.

E. J. C.

**Determination of chlorine in mixtures containing silicates.** G. BRUHNS. *Z. angew. Chem.* 31, I, 156(1918); *J. Soc. Chem. Ind.* 37, 578A.—Cl can be detd. by titration with  $\text{AgNO}_3$  in the presence of dissolved or gelatinous silicic acid (water glass, detergents, etc.), provided that the liquid is made neutral to phenolphthalein with  $\text{HNO}_3$  and any resulting gelatinous mass is finely distributed by trituration or shaking.

E. J. C.

**The gravimetric determination of sulfate as barium sulfate.** I. M. KOLTHOFF AND E. H. VOGELZANG. *Utrecht. Pharm. Weekblad* 56, 122-42(1919).—The literature of  $\text{BaSO}_4$  detns. is reviewed, with the following conclusions: The soly. of  $\text{BaSO}_4$  (2.3 mg. per l. at room temp.) is much increased by rising temp. or by the presence of  $\text{HNO}_3$ , and to a less extent by the presence of  $\text{HCl}$ . Dry ignition in porcelain, or moist ignition in Pt, causes little or no reduction; dry ignition in Pt causes a great deal. It is advisable in any case to add a few drops of  $\text{H}_2\text{SO}_4$  and ignite again to const. wt. The statement of Pregl (*Quantitative organische Microanalyse*, p 29(1917)), that occluded salts can be washed out after ignition, is incorrect. The occlusion of  $\text{BaCl}_2$ , nitrates, Ca, Fe and K is chem. in nature. The error caused by the presence of phosphates is due to the formation of the Ba phosphate. It is impossible to prescribe a general procedure for the accurate detn. of  $\text{SO}_4$  in arbitrary mixts. Cf. following abstr.

JULIAN F. SMITH.

**The determination of sulfates as strontium sulfate.** I. M. KOLTHOFF AND E. H. VOGELZANG. *Utrecht. Pharm. Weekblad* 56, 159-61(1919).—The detn. of  $\text{SO}_4$

as  $\text{SrSO}_4$  is subject to the same errors as in the case of  $\text{BaSO}_4$ . The use of 50% EtOH makes the soly. sufficiently low; but free acids and certain salts, especially  $\text{NH}_4$  salts, act as disturbing factors. The soly. of  $\text{SrSO}_4$  in mg. per l., was detd. at  $19^\circ$  for different solvents as follows: 25% EtOH, 19; 50% EtOH, 0; 50% EtOH + 0.1 N HCl, approx. 120; 50% EtOH + 0.1 N  $\text{NH}_4\text{Cl}$ , approx. 40;  $\text{H}_2\text{O}$ , approx. 114. Cf. preceding abst.

JULIAN F. SMITH.

**Sampling of dust in mine-air.** J. BOYD. *Eng. Mining J.* 107, 395-6(1919).—The method, evolved on the Rand, consists in passing a known vol. of air through a known wt. of pure sucrose. The sucrose, dampened with the moisture present in the mine air, becomes sticky and catches all of the dust in the air passed through it. The sucrose is then dissolved in hot  $\text{H}_2\text{O}$  and the residue of dust filtered off and weighed. An air suction pump consisting of a metal cylinder 22 in. high and of 3 in. diam., double acting and fitted with ball valves, is the principal part of the sampling app. The pump should be calibrated at least once a month against a standard air meter. The sucrose containers consist of a glass tube (5 in.  $\times$   $1\frac{1}{4}$  in.) fitted at the top with a solid rubber stopper and at the bottom with a rubber stopper through which passes a glass tube. On top of the latter stopper is placed a wad of cotton wool; then 40 g. of sucrose, ground to pass a 10-mesh and remain on a 20-mesh sieve, are placed in the tube, and the solid stopper is inserted. The inlet pipe in the pump and the glass tube projecting from the bottom of the sugar tube are connected by 6 ft. of  $\frac{1}{2}$ -in. rubber tubing. The details of testing the app. and taking samples, and the the precautions to be observed, are given.

F. W. SMITHER.

**Silver-asbestos, lead chromate-asbestos and lead peroxide-asbestos for use in combustions.** O. BINDER. *Chem. Ztg.* 42, 522(1918); *J. Soc. Chem. Ind.* 37, 784A. —The use of Ag-asbestos is recommended in place of Ag foil for the removal of Cl in combustion analyses. It is prepd. by reducing ammoniacal  $\text{AgNO}_3$  soln. with metallic Zn, washing and drying the finely divided pptd. Ag, and then mixing it with ignited asbestos. A mixt. of asbestos and  $\text{PbCrO}_4$  or  $\text{PbO}_2$  is useful for the absorption of S compds.

E. H.

**Separation of formic, acetic, and lactic acids.** I. ONODERA. *Ber. Ohara Inst. landw. Forsch.* 1, 231-59(1917); *J. Soc. Chem. Ind.* 37, 715-6A.—The soln. contg. the 3 acids is extd. with ether for 4 hrs. in a modified Soxhlet app., the extn. flask contg. an excess of 0.1 N NaOH soln. The excess of alkali is then neutralized with 0.1 N  $\text{H}_3\text{PO}_4$  soln. (this gives a measure of the total acidity), an excess of  $\text{H}_3\text{PO}_4$  is added, and the mixt. steam-distd. at  $140$ - $160^\circ$  for 2 hrs. or until the distillate no longer shows an acid reaction; the distillate is collected in an excess of alkali soln., the latter neutralized with  $\text{H}_2\text{SO}_4$  and dild. to a definite vol. To det. the formic and lactic acids an aliquot portion of this soln. is treated with 1.5 g. of  $\text{Na}_2\text{CO}_3$  and an excess of 0.1 N  $\text{KMnO}_4$  soln., dild. to 100 cc., and heated at  $100^\circ$  for 35 min., and the excess  $\text{KMnO}_4$  detd. iodometrically. Another portion of the soln. is then heated for 1 hr. at  $100^\circ$  with the addition of 1.5 g. of  $\text{Na}_2\text{CO}_3$  and excess of 3.2%  $\text{KMnO}_4$  soln., the excess of the latter is destroyed with  $\text{H}_2\text{O}_2$ , the mixt. filtered, the filtrate evapd., and the oxalic acid formed by the oxidation of the lactic acid is pptd. as Ca oxalate and this is titrated in the usual way with permanganate soln. Each cc. of 0.02  $\text{KMnO}_4$  soln. is equiv. to 0.0009 g. of lactic acid; the formic acid is found by difference. AcOH is detd. by oxidizing a third portion of the soln. as described, decomposing the excess of  $\text{KMnO}_4$  with  $\text{H}_2\text{O}_2$ , evapg. the filtered liquid, acidifying the residual liquid with  $\text{H}_2\text{SO}_4$ , and extg. it with ether, the extn. flask in this case contg. a small quantity of water. A portion of the ext. is then dild. to 100 cc. and distd., 95 cc. of distillate being collected and titrated. Under these conditions 84.49% of the AcOH is found in the distillate.

E. J. C.

**Determination of fructose in the presence of aldoses.** HERZFELD AND LENART. *Zentr. Zuckerind.* 68, 227(1918); *Chem. Ztg.* 42, 135; *J. Soc. Chem. Ind.* 37, 632A.—A quantity of the substance contg. about 1 g. of fructose is dissolved in water, the soln. clarified with Pb acetate, dild. to 100 cc., and filtered; 50 cc. of the filtrate is then inverted (Clerget-Herzfeld method), cooled, and treated with Br, 1 cc. of the latter being added for each g. of aldose present. The mixt. is shaken occasionally for 24 hrs., whereby the aldoses, and these only, are oxidized. The excess of Br is evapd. on the water bath, the mixt. neutralized, then treated with a few drops of AcOH, dild. to 100 cc., and the fructose detd. from the reducing power of the soln., using the Hönig-Jesser table. E. J. C.

**Determination of halogens in organic compounds by catalytic reduction.** M. BUSCH. *Z. angew. Chem.* 31, I, 232(1918); *J. Soc. Chem. Ind.* 38, 57A.—In the catalytic reduction of org. halogen compds. by means of Pd, hydrazine (which is decomposed by the catalyst into N and H) may be substituted with advantage for a current of purified H (cf. C. A. 10, 2727). Dissolve 0.2 g. of the org. compd. in 40–50 cc. of alc.; add 2 g. of palladinized  $\text{CaCO}_3$  or  $\text{BaSO}_4$ , 2.5 cc. of 50% KOH, and 10 drops of hydrazine hydrate. Boil the liquid under a reflux condenser for  $\frac{1}{2}$  hr. after which expel the bulk of the alc. by heating. Filter off the catalyst, and det. the halogen in the filtrate. E. J. C.

Some properties of magnesium ammonium phosphate and magnesium pyrophosphate (KARAOGLANOW, DIMITROW) 6. Recovery of molybdenum from residues (MALOWAN) 6. ## 8. MINERALOGICAL AND GEOLOGICAL CHEMISTRY.

EDGAR T. WHERRY AND J. H. BOWER.

**Crystallography of some Canadian minerals: stephanite, epidote, and calamine.** EUGENE POITEVIN. *Geol. Survey Can. Am. Mineral.* 4, 22–5(1919); cf. C. A. 13, 551.—The associations and crystallography of occurrences of these 3 minerals are described in detail. E. T. W.

**An unusual sulfur crystal.** F. RUSSELL BICHOWSKY. *J. Wash. Acad. Sci.* 9, 126–31(1919).—A crystallographic description of a rhombic S crystal formed by the accidental mixing of a hot EtOH soln. of  $(\text{NH}_4)_2\text{Sx}$ , with a mixt. of benzonitrile, hydroxylamine hydrochloride, and  $\text{Et}_2\text{O}$ . All available data on the crystallography of this form of S are summarized. S. G. GORDON.

**Planchete and shattuckite, copper silicates, are not the same mineral.** WALDEMAR T. SCHALLER. *J. Wash. Acad. Sci.* 9, 131–4(1919); cf. Zambonini, C. A. 12, 1448.—Three analyses of shattuckite establish the formula  $2\text{CuO} \cdot 2\text{SiO}_2 \cdot \text{H}_2\text{O}$ , whereas plancheite, as revized, is  $6\text{CuO} \cdot 5\text{SiO}_2 \cdot 2\text{H}_2\text{O}$ . The  $n_s$  further preclude their being identical, new detns. by Larsen giving: shattuckite,  $\alpha = 1.752$ ,  $\beta = 1.782$ ,  $\gamma = 1.815$ ; plancheite,  $\alpha = 1.645$ ,  $\beta = 1.660$ ,  $\gamma = 1.715$ ; another sample,  $\alpha = 1.640$ ,  $\beta$  n. d.,  $\gamma = 1.715$ . It is suggested that Z.'s mineral was really shattuckite and not plancheite, or that his material if plancheite contained enough impurities to approximate the compn. of shattuckite. S. G. GORDON.

The pyritiferous deposit at the contact of the granite at Chizeuil, Saone-et-Loire, and its metamorphic rocks. A. LACROIX. *Bull. soc. franc. min.* 41, 14-21(1918).—The occurrence and associations of the rocks and their minerals are described. An analysis of andalusite by Pisani is given, and the properties of this and several other minerals are described. The rarest of these is svanbergite, which occurs in measurable crystals giving the usual forms and showing qualitatively the presence of Sr, Al,  $P_2O_5$  and  $SO_4$ . The course of the metamorphism resulting in the production of the rocks is discussed.

E. T. W.

The minerals of the grits of Segalas, Tunis. P. GAUBERT. *Bull. soc. franc. min.* 41, 33-8(1918).—This deposit contains an unusual number of heavy minerals, of which brief descriptions are given. It was found to be an easy matter to distinguish some of them by study under the microscope after melting in S.

E. T. W.

Some fashioned objects from Timbuctu. P. GAUBERT. *Bull. soc. franc. min.* 41, 38-40(1918).—By detns. of  $d$  and  $n$ , and by microchem. tests, amazonite and lazulite were recognized. Neither has as yet been found in place in Africa.

E. T. W.

A general summary of the mineral production of Canada during the calendar year 1917. JOHN MCLEISH. Can. Dept. of Mines, Mines Branch, Adv. Chapter, *Ann. Rept. on Mineral Production of Canada during 1917*, No. 499, 27 pp.(1919); cf. C. A. 12, 978.

E. J. C.

Deposits of gold in French colonies and particularly in Madagascar. A. LACROIX. *Rev. sci.* 56, 225-33(1918).—The deposits in Madagascar are described from the geologic and petrographic points of view. Statistics of the production and export of Au are given for the period 1902-1915.

L. W. RIGGS.

Oilology. A. PETERSON. *Oil & Gas J.* 17, No. 37, 40(1919).—In the Mid-Continent oil fields ocean currents flowed from the northeast to the southeast, carrying org. matter which was deposited at various points. Thus where the bed of the ocean formerly had been the oil will always be found and not necessarily always will there be domes or ridges. P. attempts to disprove the anticlinal theory, and does not believe there have been uplifts or faulting which allows lighter oil to filter up. The oil is found where it was originally produced from organic remains.

R. R. MATTHEWS.

Report on the Colorado coal field of Texas. N. F. DRAKE. Univ. Texas, *Bull.* 1755, 75 pp.(1917).—Seven analyses of coal, and one of clay, are given.

S. G. GORDON.

Texas granites. J. P. NASH. Univ. Texas, *Bull.* 1725, 8 pp.(1917).—Large deposits of gray, red and pink granite occur in Burnett, Gillespie, Llano, and Mason counties, Texas. Absorption tests and the compressive strength, and four analyses of the granites are given.

S. G. GORDON.

A spilitic facies of Lower Carboniferous lava-flows in Derbyshire. HENRY C. SARGENT. *Quart. J. Geol. Soc.* 73, 11-25(1918).—The lavas of Derbyshire, of Lower Carboniferous age, embrace rocks of spilitic and mugearitic types, and basalt, both having been derived from a common magma. These rocks are described, and analyses given.

S. G. GORDON.

Enstatite-dacite from the Figeac region and an enstatitic, feldspar-free lava, analogous to boninite, from Madagascar. A. LACROIX. *Bull. soc. franc. min.* 41, 43-52(1918).—Dacite from Figeac, Lot, France, is described petrographically, with analyses by Raoult of 2 different types. For comparison with type A analyses of 4 other similar rocks have been made: dacite from Mt. Pelee, eruption of 1902; that of the last eruption of Bandai San, Japan (after Wada); esterellite, Boulouris, Esterel, France; and hornblende-augite-hypersthene dacite from Antibes, Var, France. Type b

is compared with quartz-basalt from Martinique and norite from California. Cumbrante from Scotland also shows similar characters. A peculiar rock from Makobo, Madagascar, has also been analyzed by Raoult, and shows close resemblance to one of the above types, as well as to a hypersthene basalt from Mexico. It is also like boninite from Japan, but no accurate analysis of this is available for comparison.

E. T. W.

**The geology of Terrell County.** D. D. CHRISTNER AND O. C. WHEELER. Univ. Texas, *Bull.* 1819, 1-32(1918).—A physiographic and stratigraphic report. Three analyses of spring waters and one of well water are given.

S. G. GORDON.

**Geologic exploration of the southeastern front range of Trans-Pecos, Texas.** C. L. BAKER AND W. F. BOWMAN. Univ. Texas, *Bull.* 1753, 67-176(1917).—Chiefly stratigraphic. Four analyses of white Caballos novaculite (Devonian) are given.

S. G. GORDON.

Radioactivity and the coloration of minerals (NEWBERRY, LUPTON) 3. The assignment of crystals to symmetry classes (TUTTON), (WHERRY) 2. The classification of mimetic crystals (WHERRY, ADAMS) 2. The syn-crystallization of potassium and ammonium nitrates (CAILLART) 6. Determination of the principal indices of refraction of anisotropic substances (LEDoux) 2. Optical properties of magnesium chloroplatinate (GAUBERT) 2. Analyses of county limestone deposits (AMES) 15.

## 9. METALLURGY AND METALLOGRAPHY.

WILLIAM BRADY, WILLIAM T. HALL.

**Economics of combustion in metallurgical operations.** M. ESCHER. *Stahl u. Eisen* 38, 977-82(1918); *J. Soc. Chem. Ind.* 38, 18A.—The dissoc. temp. of  $\text{CO}_2$  in presence of incandescent C, the temp. at which C and O combine to form CO, is  $1300-1400^\circ$  under practical conditions. It is the highest temp. obtainable by combustion of CO (producer gas), above which the monoxide and O co-exist uncombined; but combination takes place as soon as the temp. falls below the dissoc. point. Higher temps. are attained by the combustion of C, H, or hydrocarbons. In open-hearth furnaces fired with producer gas, in which the charge melts at about  $1300^\circ$ , CO does not contribute to the raising of the temp. beyond that point and after this temp. is reached combustion of the CO takes place only in the regenerators. Only the H and hydrocarbons present in the producer gas are of value for raising the temp. further. Hence the vol. of gas blown in must be increased. The most economical manner of working would consist in melting down the metal with producer gas and finishing the charge with a gas rich in hydrocarbons. In cupola furnaces, the O-CO mixt. is formed at the tuyères, and combination to  $\text{CO}_2$  takes place higher up in the shaft in contact with the cooler charge. Where  $1300-1400^\circ$  has to be exceeded in foundry work, the most economical appliance would be a cupola with an upper and lower set of tuyères. The Fe would be melted down in the zone above the upper tuyères; in the lower part, where the furnace works as a gas-producer, the molten metal would become superheated.

E. J. C.

**Electrical valve control.** ANON. *Eng. Mining J.* 107, 411-2(1919).—A description of the application of the Dean valve control system to large blast furnace air valves. The feature of the system is that instead of the automatic cutoff of the power occurring before closing and depending on drift to close the valve, the gate is seated home and then the gears are thrown off. In this way the motor cannot jam the gate by its momentum. The system may be applied to any ordinary gate valve.

W. L. BADGER.

Cobalt, molybdenum, nickel, titanium, tungsten, radium, uranium and vanadium in 1916. FRANK L. HESS. U. S. Geol. Survey, *Mineral Resources of U. S.*, 1916, Part I, 775-807 (preprint No. 25, published Feb. 25, 1919). E. H.

The value of sulfur in ores, with special reference to blende-roasting contracts. R. PAUL. *Metall u. Ers* 15, 371-86 (1918); *J. Soc. Chem. Ind.* 38, 18A.—In high-grade sulfides (e. g., pyrite) S. has a positive value, while the contrary is the case with medium- and low-grade sulfide ores. Values of S in Spanish pyrite are given. By calcg. the cost and profits of  $H_2SO_4$  manuf., the value of the S in blende was also worked out. The value of S in blende is lower than that of S in pyrite, due chiefly to the higher working-cost, as blende must be dead-roasted, while pyrite is less thoroughly calcined with a view to a large output in acid. E. J. C.

Zinc content of furnace ashes. O. MÜHLHAUSER. *Metall u. Ers* 15, 259-65 (1918); *J. Soc. Chem. Ind.* 37, 626A.—The Zn content of the ashes from the muffles varied from 2.9 to 14.5%, the total loss being on the av. about 10%. The ashes near the throat of the muffle contd. about 35% Zn, compared with an av. of just over 4% in the hinder part. The Zn present varied from 2.9 to 57% along the whole length of the muffle, due chiefly to the lower temp. at the throat, but also to the deposition of Zn oxide formed by the action of air entering between the muffle and the condenser. The Zn content of the ash increases but slowly at first from 3 to 6% over a distance of 105 cm. from the rear end of the muffle, finally rising rapidly in the last 20 cm. of the muffle. The Zn is present in the ashes chiefly as oxide and sulfide; if Fe is present the latter is reduced to metal. E. J. C.

Zinc slags. O. MÜHLHAUSER. *Metall u. Ers* 15, 303-5 (1918); *J. Soc. Chem. Ind.* 37, 658A.—The amt. of slag formed in the retorts during distn. should be small, and its compn. should be controlled by mixing the charge in suitable proportions so that it has as little action on the retort as possible. An av. slag sample obtained by distg. a mixt. of Joplin and Wisconsin ores was found to have an O ratio of 1:2.8, approaching that of a trisilicate. It was very viscous at distn. temps. and formed an internal coating, the thickest part of which was on the bottom of the retort. The latter was thus protected from corrosion, and the loss of Zn by vapor diffusion decreased. E. J. C.

Glazes on zinc retorts. O. MÜHLHAUSER. *Metall u. Ers* 15, 393-5 (1918); *J. Soc. Chem. Ind.* 38, 42A.—When Zn distg. furnaces are heated with coal rich in Fe, the volatile matter and dust from the fuel may attack the retorts and interior of the furnace, forming glaze-like materials which eventually collect into drops. If the glaze falls from one retort on to a lower one it may cause extensive erosion. Analyses of several "glazes" are given. Their compn. varies with the fuel and the conditions in the furnace. The "glazing" of the retorts is advantageous, as it restricts loss due to diffusion of Zn vapor through the wall of the retort; hence natural gas and Mond gas appear to be undesirable fuels, because their freedom from flue-dust precludes the formation of "glazes." These gases might be utilized, however, if a suitable artificially prepd. glaze could be applied to the retorts. E. J. C.

Extraction of mercury from its ores by sodium sulfide. C. H. HOLLAND. New Zealand. *J. Sci. Tech.* 1, 153-4 (1918); *J. Soc. Chem. Ind.* 37, 548A.—One part of an ore contg. cinnabar,  $Fe_2O_3$ , and a hydrocarbon is crushed, and agitated with 4.5 parts of an aq. soln. contg. 4% Na sulfide and 1% NaOH. The soln. is filtered and Hg is pptd. from the double sulfide of Hg and Na by Al shavings. The Hg is obtained partly in metallic form, and partly as a powder mixed with foreign matter, which is heated in a retort with  $MnO_2$  and lime. The total yield of Hg is 84.5%. E. J. C.

**Blast furnace treatment of low grade manganese ores.** R. CORDES. *Stahl u. Eisen* 37, 494-7(1917); *Rev. métal.* 15, Extraits, 310-2(1918).—Low-grade carbonate ore from the Siegerland district is hand-picked, or concd. by an electromagnetic process. The value of the concentrate as a source of Mn is the smaller the higher its  $\text{SiO}_2$  content. In smelting for pig-iron contg. 3.5-4% Mn, the slag normally takes up 3% Mn; hence the Mn content of the metal decreases as the quantity of slag increases. Ore of the best quality assays  $\text{SiO}_2$  10, Fe 48, and Mn 9%; ores contg. more than 30%  $\text{SiO}_2$  must be concd. E. J. C.

**Impurities in and purification of commercial aluminium.** ANON. *Ber. Physik.-Techn. Reichsanstalt* 1917; *Stahl u. Eisen* 38, 1044-5(1918); *J. Soc. Chem. Ind.* 38, 17A.—The impurities in 4 samples of com. metal varied from 0.4 to 2%. These were chiefly Fe and Si, with lesser amts. of C and traces of S, P and N. The analytical methods for detg. the impurities are as yet imperfect. The bulk of the Al may be eliminated as chlorine by satg. the acid soln. with HCl. The purification of the com. metal is difficult; Si may be largely removed by fusion with niter, but not the Fe. The bulk of the latter can be dissolved by digesting the metal with 2% HCl; borings contg. 1% Fe gave 60% of purified metal with less than 0.1% Fe. E. J. C.

**Melting of gray iron in an oil-fired furnace.** K. ABEKING. *Stahl u. Eisen* 38, 792-5(1918); *J. Soc. Chem. Ind.* 37, 624A.—A. describes the production of gray iron castings of special quality in furnaces of the oil-fired "drum" pattern without a crucible. The first cost of an installation for  $\frac{1}{2}$  ton melts is given as M. 5000-6000 (\$1,190-1,428). The furnace, which takes up little room and is equally satisfactory for other metals than Fe, is much more costly to run than a cupola. The iron can be run in a very fluid condition for thin castings, and less labor is required than for a cupola. The tensile strength of the cast Fe ranges from 21.7 to 30 kg. per sq. mm. The total C may vary from 2.45 to 3.26%, and the S from 0.062 to 0.12%. The Brinell hardness of the Fe varies from 160 to 180. The charge used consists of 5-10% of steel scrap, 20% of hematite Fe, and the rest foundry irons. The Si loss during melting reaches 15-20%. The av. heat lasts 2 hrs. E. J. C.

**Utilization of ash of pyrites in Italian steel making.** ALFREDO LOTTI. *Follonica. Bollettino del comitato centrale di mobilitazione industriale* 12, 196FF(1918); *Met. italiana* 10, 242-7(1918).—The ash is the residue from washings of pyrites in production of  $\text{H}_2\text{SO}_4$  and superphosphate. It constitutes more than half the wt. of the original pyrites. The 3 principal factors hindering the use of the ash are impurities in the ash (considering the ash as an Fe ore), distance from the metallurgical centers of utilization, and physical state of aggregation. The compn. of an av. sample of ash is as follows: insol. residue 11.60%,  $\text{Fe}_2\text{O}_3$  79.96 (= 55.93 Fe),  $\text{Al}_2\text{O}_3$  5.28,  $\text{SO}_3$  3.43 (= 1.37 S), ZnO. 0.64%. The S occurs as sulfide and sulfate, chiefly as basic Fe sulfate and  $\text{CaSO}_4$ . It is more harmful when combined with the Fe. As sulfide it passes directly into the pig Fe during reduction of the ore, and also as basic sulfate, being first reduced to sulfide.  $\text{CaSO}_4$  is not harmful, changing to sulfide and thence passing into the slag. It is important to reduce the amount of S contained in pyrites ash. The powdery or granular portion of the ash offers obstacles in the way of its utilization. This may be overcome by some form of agglomeration with binders or by fusion, with partial desulfurization in each case. ROBERT S. POSMONTIER.

**Influence of badly burnt lime in the basic steel process.** M. BACKHEUER. *Stahl u. Eisen* 38, 748-50(1918); *J. Soc. Chem. Ind.* 37, 547A.—Lime for slag making in the basic process should give a loss on ignition of not more than 2-4%, or at the highest 6%. Dead-burnt lime, however, is dissolved with difficulty in the slag. Badly burnt lime exercises a harmful influence both on the quality of the steel, resulting in non-

metallic inclusions, and also on the working of the heats as a result of the chilling effect. In the basic Bessemer process poor lime results in an excessive loss of Mn, the steel being highly oxidized. The blow is abnormal and the elimination of P in the after-blow uncertain. With badly burnt lime 1.3% Mn is the minimum necessary in the mixer-Fe used. Excessive loss during the blow and considerable production of scrap also result from the addition of incompletely burnt lime. E. J. C.

**Metals and alloys from a colloid chemical viewpoint.** JEROME ALEXANDER. *Bull. Am. Inst. Mining Eng.* 1919, 602-3.—Metals and alloys are compared to jellies or sponge-like structures having very great stiffness at ordinary temps.; the dispersion of their constituent phases depends upon chem. compn., mutual soly., speed of chilling, subsequent mechanical and heat treatment, "protective" action or crystal inhibition, etc. The use of the ultramicroscope is urged to develop the cause of the structure revealed by ordinary metallographic pictures. Analogies are drawn between metals and transparent soap, gold ruby glass, etc. JEROME ALEXANDER.

**Examination of metals by X-rays.** H. PILON. *J. Röntgen Soc.* 14, 17(1918).—A number of radiographs are given illustrating the application of X-rays to the examn. of metals by means of Collidge tubes and specially designed app. The radiographs demonstrate the faulty welding of an Fe tank, the rays passing through 20 mm. thickness of Fe, a fault in the Al gear case of an aircraft engine, where air holes in the Al had been filled with an alloy of greater density, etc. F. P. PHELPS.

**The Curie point in pure iron and in ferro-silicon.** A. SANFOURCHE. *Compt. rend.* 167, 683-5(1918).—At about 1280° Fe undergoes a transformation with respect to its magnetic properties and this is referred to here as the Curie or A<sub>1</sub> point. Recently this transformation has been detected by different investigators at varying temps. so that it seemed desirable to work with very pure materials to det. exactly where the change takes place normally. With such a material, the transformation was detected at 1310° on cooling and at 1365° on heating. Very pure, crystallized Si was then added to the Fe and it was found that the transformation took place at a lower temp. With 2% and with 2.5% Si, the A<sub>c</sub> temp. was at 1297° and the A<sub>r</sub> temp. was at 1225° and 1195°, respectively. W. T. H.

**A metallographic investigation of transverse fissures with special reference to high phosphorus streaks.** G. F. COMSTOCK. *Bull. Am. Inst. Mining Eng.* 1919, 598-602; cf. C. A. 13, 226.—In discussing the paper, James E. Howard points out that transverse fissures may be the result of fatigue, grade of steel, or mill practice. He places particular emphasis upon the fatigue of the steel and belittles any attempt to place the blame entirely upon the presence of microscopic flaws. The intense internal strains which develop in the use of rails make it seem probable that service conditions have reached that stage in which the ability of steel to withstand them has nearly reached its limit. W. T. H.

**A comparison of grain-size measurements and Brinell hardness of cartridge brass.** W. H. BASSETT AND C. H. DAVIS. *Bull. Am. Inst. Mining Eng.* 1919, 607; cf. C. A. 13, 307.—In the discussion of the paper W. R. Hibbard states that the technical dept. of the Am. Brass Co. has discarded grain measurements and relies upon Brinell detns. as a guide to the serviceability of cartridge brass of 0.1 in. gage or more. W. T. H.

**The premature rupture of pieces of steel subjected to repeated shocks.** CH. FRÉMONT. *Compt. rend.* 168, 54-6(1919).—In order that a piece of metal which is subject to alternating stresses and strains shall not deteriorate, it is necessary that the quantity of work borne by each part shall be absorbed elastically and that at no moment shall there be a strain or stress above the elastic limit of that part. On the

basis of such a theory it has been found possible to increase the life of axles of railroad cars, etc., by modifying the design of the material. The weakness of material is usually due to lack of homogeneity and it is pointed out that evidence of trouble caused by slag lines was noted by Piobert in 1836.

W. T. H.

**Corrosion of brass in sea water.** PAUL T. BRUHL. *Chem. Met. Eng.* 20, 239 (1919).—A general discussion of the influence of various corrosion products on the rate of corrosion.

W. T. H.

**A technical study of acid-Bessemer steel.** RICHARD S. MCCAFFERY. *Iron Age* 103, 626-7(1919).—From chem. examination of samples taken at various stages of work in the Bessemer converter, important conclusions regarding the changes that take place during the "acid Bessemer blow" have been drawn. During the "blow," FeSi burns first, forming  $\text{Fe}_2\text{O}_3$  and  $\text{SiO}_2$  and, as a result of the large amt. of heat liberated, the temp. rises.  $\text{Mn}_2\text{C}_3$  should be the next to burn to form MnO and  $\text{CO}_2$ . The  $\text{Fe}_2\text{O}_3$ , MnO and  $\text{SiO}_2$  unite to form an Fe-Mn-SiO slag. The temp. continues to rise and the  $\text{Fe}_2\text{C}$  begins to be oxidized. When nearly all the C has been acted upon, the Bessemer converter is ready to be turned down and its contents poured, at a temp. of 1600-1700° under normal conditions. Under these conditions no trouble is experienced. If, on the other hand, the temp. of the converter becomes too high, possibly because too much FeSi was in the pig Fe,  $\text{Mn}_2\text{Si}_3$  may begin to burn after the FeSi has been oxidized and while  $\text{Mn}_2\text{C}_3$  is left in the molten metal. This begins to cause trouble by reducing  $\text{Fe}_2\text{O}_3$  and  $\text{SiO}_2$ , making the slag more basic and making it possible to form some ferrite slag. The slag becomes less fusible and "spitting" ensues. This continues until all the  $\text{Mn}_2\text{C}_3$  has been eliminated. The  $\text{Fe}_2\text{C}$  then oxidizes and when sufficiently acted upon the blow is finished. The reaction  $2\text{Mn} + \text{O}_2 = 2\text{MnO}$  does not appear to be reversible in the converter. By steaming during the Si blow, the temp. can be kept low so that the  $\text{Mn}_2\text{C}_3$  is oxidized early in the operation without exerting any harmful effect. Certain observations indicate that  $\text{CO}_2$  rather than CO may be formed during the burning of the  $\text{Fe}_2\text{C}$ . By using a new converter bottom with increased no. of tuyères distributed in a new manner a large saving in time and power was effected. The blast pressure was reduced with the new converter bottom and air was not wasted in burning C to CO.

W. T. H.

**Metallographic examination of tinplate.** LEO MAYER. *Stahl u. Eisen* 1918, 960-2; *Engineering* 107, 150(1919).

W. T. H.

**Strength of solders at elevated temperatures.** C. W. HILL AND C. H. CARPENTER. *Metal Ind.* 17, 82(1919).—Cu cylinders of 0.5 in. bore were soldered together end to end in such a way that 0.005-0.05 in. of solder was between the 2 cylinders. The tensile strength of the joints was then tested at temps. ranging from 20° to 1400°. The solders used were (1) "half and half," (2) pure Sn, (3) a special solder composed of 90.6 Pb, 7.9% Cd, 1.5% Zn. The breaking strength fell off steadily as the temp. was raised. At 20° the joints showed a breaking strength of 11,000 to 12,000 lbs. per sq. in., but at 1400° the first solder had practically no strength, the second solder broke at 3,000 lbs. per sq. in. and the third at 6,000 lbs. per sq. in.

W. T. H.

**Solders for aluminium.** ANON. *Bureau Standards Circ.* 78(1919).—All metals used for soldering Al are electrolytically negative to Al and the joint is subject to rapid corrosion. Unless very heavy, so that surface corrosion is unimportant, all soldered joints should be protected. The solders are best applied without flux after preliminary cleaning and tinning of the surface. The solder should consist of a Sn base with additions of Zn or Zn and Al. The higher the temp. of tinning, the better is the adhesion. The tensile strength of a good joint is about 7,000 lbs. per sq. in.

W. T. H.

**Welding mild steel.** H. M. HOBART. *Bull. Am. Inst. Mining Eng.* 1919, 517-61. —In connection with emergency ship building during the war, welding has replaced

riveting to a considerable extent. Results are recorded here of a great many expts. which were performed in the study of the various methods of making welds and methods for testing them. The adequacy of welding as a substitute for riveting may be regarded as demonstrated by actual practice in ship-building. W. T. H.

A comparison between American and British practice in electric welding. S. V. GOODALL. *Engineering* 107, 254-6(1919).—Americans favor spot welding for bracket connections while the British prefer rivetting. For right-angled water-tight connections, Am. practice tends to heavy welding, the British to rivetting, or to notch angles with light intermediate rivetting. In England, welding is not applied to mild steel plates of greater thickness than the 25 lb. plates but no such limits have been set in the U. S. W. T. H.

Oxy-acetylene welding. J. H. DAVIES. *Engineering* 107, 169-70(1919).

W. T. H.

The development of the oxy-acetylene welding and cutting industry in the United States. HENRY CAVE. *Engineering* 107, 170-3(1919).

DESCH, C. H.: Introductory Lecture to the Classes in Metallurgy in the Royal Technical College, Glasgow. Session 1918-19. Glasgow: J. Maclehose & Sons.

JINZES, W. H.: *Ijzer, Kool en Zuurstof. Een eenvoudige Leerboek voor Ambachtsonderwijs en zelfstudie.* 2nd Ed. Deventer: A. E. Kluwer. 84 pp. f 1.25. For review see *Chem. Weekblad* 16, 184(1919).

Ore-concentrator and amalgamator. E. B. BENNETT. U. S. 1,292,684, Jan. 28.

Sintering ores. A. H. RICHARDS. U. S. 1,292,059, Jan. 21. Ore to be sintered is formed into a layer, the top surface of the layer is ignited, a draft is passed downwardly through the ore to carry the burning zone gradually through the layer and a second layer of ore is deposited on the first layer when the burning zone has penetrated the first layer to a suitable distance.

Amalgamator for treating ores. J. GARSIDE. U. S. 1,292,753, Jan. 28.

Recovering metals from ores. R. GAHL. U. S. 1,291,824, Jan. 21. Ores of Cu or other metals are deslimed, subjected to a flotation treatment to produce a middling product and the latter and also the tailings are leached to obtain a metalliferous soln., after the middling product is roasted. The method is especially adapted for treatment of porphyry Cu ores.

Extracting values from manganese ores. E. W. HASLUP and B. A. PRACOCK. U. S. 1,291,867, Jan. 21. Finely divided ore containing Mn and other metals which are attacked by  $H_2SO_4$ , such as K, Al, Zn, Ni, Co, Cu or W, is treated with concd.  $H_2SO_4$  and the reaction of the acid on the constituents of the ore is allowed to proceed in a closed vessel until the mixt. attains a temp. above  $100^\circ$  and substantially all the Mn and other values have been converted into sulfates. The latter are then extd. from the mass and Mn values may be recovered from the soln. thus obtained by pptn. and fractional sepn. Cf. C. A. 12, 567.

Hydrometallurgy of copper. W. N. ROSSBERG and G. E. SHERIDAN. U. S. 1,292,075, Jan. 21. Cu is recovered from oxidized ores by leaching with  $H_2SO_4$  to ob-

tain a soln. of  $\text{CuSO}_4$ , the Cu is pptd. from the soln. as  $\text{Cu}_2\text{S}$  in the presence of  $\text{SO}_2$  by the addition of  $\text{H}_2\text{S}$ , and the acid soln. regenerated by this last procedure is used for leaching additional quantities of ore and for decomposing sulfide to produce  $\text{H}_2\text{S}$  for further use in the process.

**Reducing iron in blast furnaces.** H. B. WEAVER and J. GAYLEY. U. S. 1,292,937, Jan. 28. In operating blast furnaces, the process is carried on to produce Fe and slag as usual and to produce by a heated air blast, supplied under pressure, an atm. of reducing gas in contact with the ignited fuel. Such portions of the reducing gases are withdrawn from the furnace as are not necessary for maintaining the required reducing conditions in the stack, and *compds. of alkali metals* are extd. from the gases so withdrawn. The withdrawal may take place intermittently to permit accumulation of alkali metal carbonate between the periods of withdrawal.

**Pure iron.** R. K. MUENCH. U. S. 1,292,630, Jan. 28. The pat. relates to the obtainment of pure Fe from  $\text{FeCl}_3$  solns. containing impurities, such, *e. g.*, as the liquor obtained by pickling Fe with HCl, or a soln. especially prepd. for the purpose by dissolving impure Fe in HCl. The soln. is evapd. to expel any excess of acid present, care being taken so far as possible not to permit oxidation.  $\text{K}_4\text{Fe}(\text{CN})_6$  is added to ppt.  $\text{K}_2\text{Fe}(\text{CN})_6$ , the ppt. is filtered out and, while still moist, is treated with somewhat more than a combining proportion of HCl with respect to the amt. of Fe present. Concd. solns. are used. The ppt. and HCl are heated together with addition of  $\text{H}_2\text{O}$  (after preliminary evapn. nearly to dryness) and the mixt. is boiled for 1 hr. to obtain a soln. of  $\text{FeCl}_3$  which is substantially pure except for alkali metal *compds.* This soln. may be electrolyzed to obtain pure Fe or may be oxidized, treated with a precipitant to obtain  $\text{Fe}(\text{OH})_3$  and the latter may be ignited and the oxide so obtained reduced by H.

**Melting readily oxidizable metal scrap.** J. COULSON. U. S. 1,292,582, Jan. 28. Turnings of magnalium or other readily oxidizable metal, in subdivided form to be melted, is heated in a melting chamber (while excluding air and adding the metal in small portions) with a small amount of Ca Al silicide as a deoxidizing agent.

**Apparatus for continuously sherardizing small metal articles.** H. C. HARRISON. U. S. 1,291,866, Jan. 21.

**Carburizing material.** G. W. PRESSL. U. S. 1,292,044, Jan. 21. A dry packing material for carburizing metals is prepd. by carbonizing coconut shells in a retort and treating the carbonized material, while at a temp. near to that of distn., with an aq. soln. of  $\text{Na}_2\text{CO}_3$ .

**Annealing copper and brass tubes.** J. A. MOORHEAD. U. S. 1,292,352, Jan. 21. Tubes of Cu or brass are bright-annealed by passing them through a tubular furnace of refractory material heated by an a. c. primary coil.

**Core compound.** J. S. ROBESON. U. S. 1,292,068, Jan. 21. An adhesive suitable for use in making sand cores for founding is formed of rosin size and desiccated waste sulfite liquor, with or without petroleum or other oils.

CHAS. A. ROUILLER.

**Esterification in aqueous solution.** ATTILIO PURGOTTI. Portici. *Gazz. chim. ital.* 48, II, 58-62 (1918).—P. carried out expts. in order to det. whether esterification takes place in very dil. aq. solns., to what extent it takes place and if it is influenced by the addition of various *compds.*, especially acids. AcOH and EtOH were mixed

in mol. proportions, and 50 cc. portions, with 100 cc.  $H_2O$  and 0.1  $N$   $HCl$ , resp. 10 cc. samples were removed and titrated for  $AcOH$  at 24-hr. intervals. The results showed that esterification in aq. soln. takes place to a very slight extent and reaches equil. with the esterification of about 1.2%  $AcOH$ . The addition of  $NaCl$  to the soln. accelerates and increases the esterification and equil. is reached at 7%. The addition of  $HCl$  and  $H_2SO_4$  accelerates and increases the esterification considerably which now reaches equil. quite quickly with 19% esterified. The addition of more acid increases the velocity of esterification still more but the final equil. comes with 19% esterified.  $NaCl$  in the same solns. increases and accelerates the esterification much as shown by the sepn. of the ester as a sep. layer and reaches equil. with 45% esterified. By diminishing the amt. of  $H_2O$  in an expt. using 60 g.  $AcOH$ , 50 g. 90%  $EtOH$ , 100 cc. satd.  $NaCl$  soln. and 20 g. concd.  $H_2SO_4$ , 55-60 g. pure  $AcOEt$  or a 70% yield was obtained.  $HCl$  and  $H_2SO_4$  accordingly act as catalysts. Additional expts. in which satd.  $NaCl$  to the extent of 1.5 times the original vol. of the  $AcOH$ - $EtOH$  mixt. was added as well as various acids and org. compds. showed the following: The catalytic power of the acids is of the same order as their dissociation consts. The acid salts like  $KHSO_4$  have a catalytic action. The org. acids also act as catalysts. Their action is slow at ordinary temp. but is quite rapid at 35° except  $(CO_2H)_2$ , which behaves nearly like an inorg. acid. Their catalytic power is of the same order as their degree of dissociation. Gallic and tannic acids retard the esterification so that it is slower than when only  $NaCl$  is used.  $K$  acid tartrate acts anticatalytically as shown also by its ability to retard the esterification with  $(CO_2H)_2$ . The catalytic effect is not limited to the carbonyl group as shown by the fact that the phenols catalyze this esterification. The most active was picric acid, next the cresols in the order, *m*-, *o*- and *p*-; *o*-, *m*- and *p*- $C_6H_4(OH)_2$  are less active than phenol and the tri- $HO$  compds. (phloroglucinol, pyrogallol) behave like gallic and tannic acids.

E. J. WITZEMANN.

$\alpha$ -,  $\beta$ -, and  $\gamma$ -Trinitrotoluenes. HUGH RYAN AND W. M. O'RIORDAN. Univ. College, Dublin. *Proc. Roy. Irish Acad.* 34B, 175-93 (1918).—Crude  $\alpha$ -trinitrotoluene is liable to contain small quantities of its  $\beta$ - and  $\gamma$ -isomers. Accidents which have occurred may be due to the presence of sensitive compds. of any one of the 3 isomers. In view of such a possibility this work was undertaken in order to det. the behavior of these isomers towards alkalis, amines, hydrocarbons, and aldehydes and the behavior of alkalis towards *sym*- $C_6H_3(NO_2)_3$ . A very thorough history of previous work done on the reaction of these reagents with the 3 isomers is given. When *sym*- $C_6H_3(NO_2)_3$  was heated with 5%  $NaOH$ ,  $NH_3$  was evolved and a dark solid formed. Extn. with  $C_6H_6$  and recrystn. from alc.- $Me_2CO$  yielded tetranitroazoxybenzene, m. 185°, sol. in  $C_6H_6$ ,  $Me_2CO$ , and alc. In  $Me_2CO$  it gave a violet color with  $NaOH$ , decolorized by  $HCl$ . Dil.  $NaOH$  reacted similarly with *sym*- $C_6H_3(NO_2)_3$ ; 5%  $Na_2CO_3$  reacted more slowly.  $BuONa$  with  $\alpha$ - $MeC_6H_3(NO_2)_3$  yielded a red solid, probably  $MeC_6H_3(NO_2)_3NaOBu$  (8.3%  $Na$ ; theory 7.1; discrepancy probably due to the presence of a dialcoholate). This compd. exploded when heated over a Bunsen flame or when dropped into a tube heated to 170°.  $\alpha$ - $MeC_6H_3(NO_2)_3$  reacted with  $KOH$  in the presence of  $I_2$  to form hexanitrodibenzyl, colorless, prismatic needles from  $C_6H_6$ , m. 210-3°. The same compd. was obtained by the reaction of  $Na_2CO_3$  and  $NaOH$  on  $\alpha$ - $MeC_6H_3(NO_2)_3$ ; it m. 216-7° (decompn.), is sol. in boiling  $C_6H_6$  or xylene and gives a red color with  $Na$ - $Hg$  and alc. and a brownish red color with  $NaOH$ . Although similar in properties, this compd. was shown not to be tetranitroazoxytoluene by prep. the latter by the method of Anschütz and Zimmerman (*C. A.* 9, 1062), and comparing the properties of the two. In an attempt to prep. hexanitrodibenzyl, dibenzyl was first prepd. by the reaction of  $Na$  with  $PhCH_2Cl$ . Nitration with  $HNO_3$ ,  $H_2SO_4$  and  $KNO_3$  yielded, however, 2,4,2',4'-tetranitrodibenzyl, colorless prisms from

$C_6H_6$ , m.  $165^\circ$ , gives a red color in alc. with Na amalgam. Attempts at further nitration failed.  $\beta$ - $MeC_6H_4(NO_2)_3$  dissolved almost completely in NaOH. Upon acidifying the soln., dinitro-*m*-cresol (Will, *Ber.* 47, 712(1914)) was obtained by crystn. from dil. alc., m.  $101^\circ$ .  $Na_2CO_3$  yielded the same results. The portion insol. in alkali exploded when heated. Both  $Na_2CO_3$  and NaOH probably yielded a dinitro-*m*-cresol, m.  $72-3^\circ$ , when heated with  $\gamma$ - $MeC_6H_4(NO_2)_3$ . From the portion insol. in alkali were obtained acicular crystals, m.  $190^\circ$ , which gave, in alc., a greenish yellow color with  $NH_3$  and was possibly a dibenzyl or stilbene deriv.  $NH_3$  reacted with  $\alpha$ - $MeC_6H_4(NO_2)_3$ , forming a dark brown amorphous residue which exploded on heating. The  $NH_3$  soln. gave a brown amorphous ppt. with acid.  $\beta$ -Dinitrotoluidine, m.  $95-6^\circ$  from alc., was obtained as a yellow solid by the action of alc.  $NH_3$  on  $\beta$ - $MeC_6H_4(NO_2)_3$ . Hepp's results (*Ann.* 215, 344) imply that this could occur only in a sealed tube. In alc. the dinitrotoluidine gave a bright red color with NaOH, turning crimson when warmed. The same dinitrotoluidine as above was obtained by the action of  $NH_3$  alone on  $\beta$ - and  $\gamma$ - $MeC_6H_4(NO_2)_3$ . When the  $NH_3$  soln. was acidified a slight brown ppt. occurred in each case.  $\alpha$ - $MeC_6H_4(NO_2)_3$  formed an additive compd. with *p*-toluidine, m.  $68-70^\circ$  (Jackson and Clarke, *Proc. Chem. Soc.* 1906, 83).  $\beta$ - $MeC_6H_4(NO_2)_3$  reacted readily with  $PhNH_2$ , yielding a dinitrotolylphenylamine, prismatic crystals, m.  $114-5^\circ$ .  $\beta$ - $MeC_6H_4(NO_2)_3$  with *p*-toluidine formed a dinitroditylamine, red prisms from alc., m.  $131^\circ$ .  $\gamma$ - $MeC_6H_4(NO_2)_3$  with *p*-toluidine formed an additive compd., yellow crystals, m.  $147^\circ$ , readily converted into a dinitroditylamine, orange solid, m.  $154^\circ$ . Thus Hepp's statement that  $\gamma$ - $MeC_6H_4(NO_2)_3$  does not form additive compds. with amines is incorrect.  $\alpha$ - $MeC_6H_4(NO_2)_3$  reacted readily with  $BzH$ , anisaldehyde, and piperonal on the  $H_2O$  bath in the presence of piperidine, forming, resp.: 2,4,6-trinitrostilbene, 2,4,6-trinitro-4'-methoxystilbene, and 2,4,6-trinitro-3',4'-methylenedioxy-stilbene (dull, yellow prisms, from  $C_6H_6$ , becoming scarlet upon losing  $C_6H_6$  of crystn.; scarlet substance, m.  $156-7^\circ$ ). Neither the  $\beta$ - nor the  $\gamma$ -isomer underwent such a transformation even at  $130^\circ$ . Phenanthrene with  $\alpha$ - $MeC_6H_4(NO_2)_3$  yielded an additive compd., bright yellow needles, m.  $98-9^\circ$ , sol. in  $C_6H_6$ ,  $Me_2CO$ ,  $Et_2O$ , or glacial  $AcOH$ ; forms a violet soln. in  $C_6H_5N$ . This compd.,  $MeC_6H_4(NO_2)_3 \cdot C_{10}H_7$ , is not decompd. by alc.,  $HCl$  or  $AcOH$ ; decompd. by NaOH, giving a violet color. Phenanthrene with  $\beta$ - $MeC_6H_4(NO_2)_3$  formed an additive compd.,  $C_{20}H_{13}N_3O_6$ , pale yellow plates from alc., m.  $105^\circ$ , sol. in  $C_6H_6$ ,  $Et_2O$ , or glacial  $AcOH$ ; decompd. by NaOH.  $\gamma$ - $MeC_6H_4(NO_2)_3$  also formed an additive compd. with phenanthrene,  $C_{20}H_{13}N_3O_6$ , dull, yellow prisms from alc., m.  $83^\circ$ , which otherwise resemble the deriv. of the  $\beta$ -isomer. The results show that although the 4 substances examd. all react differently with alkalis, in each case a reduction process occurs as shown by evolution of  $NH_3$ . The formation of an amine may be the first step in the reduction, the  $NH_2$  group being then replaced by  $OH$  with evolution of  $NH_3$ , following which reduction phenolic substances of a complex nature are formed. In the case of  $\alpha$ - $MeC_6H_4(NO_2)_3$ , oxidation occurs simultaneously with the reduction, hexanitrodibenzyl being formed. Only *s*- $C_6H_4(NO_2)_3$  yields a tetranitro-azoxy compd. In most cases dark substances insol. in alkali were formed and these exploded on being heated. The action of amines on the 3 trinitrotoluenes proceeds differently in the 3 cases. The additive compd. formed by the  $\gamma$ -isomer with *p*-toluidine contradicts Hepp's statement that this does not occur.  $\alpha$ - $MeC_6H_4(NO_2)_3$  is the only one of the trinitrotoluenes from which stilbene derivs. were obtained by the reaction of aldehydes. A significant fact in connection with the statement made in the beginning regarding the presence of sensitive compds. in the trinitrotoluenes is that a sample of crude  $\gamma$ - $MeC_6H_4(NO_2)_3$  was found to contain a dark, amorphous substance which exploded on heating.

C. H. KIDWELL.

Action of nitric acid and nitrous acid on diphenylamine. HUGH RYAN AND PHYLLIS RYAN. Univ. College, Dublin. *Proc. Roy. Irish Acad.* 34B, 194-204(1918).

—The products of the action of low concns. of  $\text{HNO}_3$  on  $\text{Ph}_2\text{NH}$  and  $\text{Ph}_2\text{NNO}$  were detd. in order to approximate conditions actually existing in a nitrocellulose explosive. The action of 1 mol. of  $\text{HNO}_3$  on  $\text{Ph}_2\text{NH}$  in glacial  $\text{AcOH}$  formed only the nitrate of the base; 2 mols. of  $\text{HNO}_3$  converted part of the amine into a brown, resinous solid, part into a yellow, oily solid, m.  $135-40^\circ$  (crystd. from alc. and  $\text{CHCl}_3$ ). 3 mols. of  $\text{HNO}_3$  also yielded the brown, resinous solid and from a similar yellow, oily solid  $[2,4-(\text{NO}_2)_2\text{C}_6\text{H}_3]_2\text{NH}$  (a) was crystd. from  $\text{Me}_2\text{CO}$ . 4 mols. of  $\text{HNO}_3$  yielded both the brown, resinous solid and the yellow solid. That part of the latter which was insol. in  $\text{CCl}_4$  was (a), m.  $198-200^\circ$  (crystd. from  $\text{Me}_2\text{CO}$  and alc.). The portion sol. in  $\text{CCl}_4$ , m.  $156-9^\circ$ , was  $(\text{NO}_2\text{C}_6\text{H}_4)_2\text{NNO}$ . 6 mols.  $\text{HNO}_3$  rapidly formed the brown solid which was filtered off; the yellow solid obtained from the filtrate by pptn. with  $\text{H}_2\text{O}$  was washed with  $\text{CHCl}_3$ . The portion insol. in  $\text{CHCl}_3$  was recrystd. from boiling xylene, and identified as (a). Evapn. of the  $\text{CHCl}_3$  ext. and treatment with  $\text{CCl}_4$  yielded  $(p\text{-NO}_2\text{C}_6\text{H}_4)_2\text{NH}$ , yellow crystals, m.  $210^\circ$  (uncor.), and unidentified orange crystals, m.  $195^\circ$ . The brown resinous solids did not melt below  $280^\circ$ , were nearly insol. and contained 12.25% N. The nitration of  $\text{Ph}_2\text{NNO}$  proceeded differently. With 1 mol. of  $\text{HNO}_3$ , o- and p- $\text{O}_2\text{NC}_6\text{H}_4\text{N}(\text{NO})\text{Ph}$  were formed. The latter consisted of colorless, leafy crystals, m.  $132-3^\circ$ , which, when boiled with alc. containing  $\text{KOH}$ , yielded p- $\text{NO}_2\text{C}_6\text{H}_4\text{NHPh}$ , S-yellow, platy crystals, m.  $131-2^\circ$ . 2 mols. of  $\text{HNO}_3$  formed yellowish white crystals, m.  $156-9^\circ$  (decompn.) and consisted of cinnabar-red 2- $\text{NO}_2\text{C}_6\text{H}_4(4\text{-NO}_2\text{C}_6\text{H}_4)\text{NH}$  (c), m.  $219^\circ$ , and 2- $\text{NO}_2\text{C}_6\text{H}_4(4\text{-NO}_2\text{C}_6\text{H}_4)\text{NNO}$  (d) (the white portion), the latter colored dark orange by  $\text{H}_2\text{SO}_4$ . From the filtrate, by pptn. with  $\text{H}_2\text{O}$ , was obtained (b), m.  $213-4^\circ$ , which, in alc., gave a violet color in the presence of a trace of alkali. From the action of 6 mols.  $\text{HNO}_3$  on p- $\text{O}_2\text{NC}_6\text{H}_4\text{N}(\text{NO})\text{Ph}$  in glacial  $\text{AcOH}$  a solid m.  $155-9^\circ$  sepd. It was probably (p- $\text{NO}_2\text{C}_6\text{H}_4)_2\text{NNO}$ . This compd., boiled with xylene under a reflux, liberated brown fumes and a portion sol. in  $\text{CCl}_4$  was obtained which m.  $205-10^\circ$  and was probably (b). (a) was obtained by pptn. with  $\text{H}_2\text{O}$  from the original  $\text{AcOH}$  soln. Each of the 3 light yellow dinitrodiphenylnitrosamines prepd. by the authors loses  $\text{NO}_2$  when heated, a property of interest in connection with heat tests for nitrocellulose powders stabilized by addition of  $\text{Ph}_2\text{NH}$ . These expts. indicate that in the absence of  $\text{HNO}_3$  the  $\text{Ph}_2\text{NH}$  is first converted into its nitrate, the color changes ranging through yellow, green and black-brown to red as the concn. of  $\text{HNO}_3$  is increased. In only one case was there a trace of nitrosamines formed during these reactions. The chief products are the brown resinous substance (a), (b) and (c). When one equiv. of  $\text{HNO}_3$  is present  $\text{Ph}_2\text{NNO}$  is first formed, being converted then into p- $\text{O}_2\text{NC}_6\text{H}_4\text{N}(\text{NO})\text{Ph}$ . In the next stage the sparingly sol., yellowish white (d) seps. from the system. (a) is the final product. 2,4-Dinitro- and 2,4,6-trinitrodiphenylamine were not isolated. A dinitrodiphenylnitrosamine is the main product in every case where  $\text{HNO}_3$  is also present. Its formation indicates the completion of the stabilizing action of the  $\text{Ph}_2\text{NH}$ . It interferes with heat tests at  $110$  or  $135^\circ$  and possibly with the Abel test. Owing to the loss of  $\text{NO}_2$  from the nitrosamine group, this compd. may lower the degree of stability of the powder.

C. H. KIDWELL.

The constitution of acetic acid. J. C. THOMLINSON. *Chem. News* 118, 23-4 (1919).— $\text{AcOH}$  vapor at  $135^\circ$  has d. 3.01, at  $300^\circ$  2.08. At the lower temp. it is assumed that the vapor has the mol. formula

while at  $300^{\circ}$  the d. corresponds to the formula  $\text{MeCO}_2\text{H}$ . Additional evidence justifying the first formula is: the sp. heat of  $\text{AcOH}$  vapor taken as 0.4 would indicate an absorption per g. mol. of  $0.4 \times 165 \times 60 = 3960$  cal. through the range of temp. in which this change occurs, corroborating conclusions drawn for a C atom changing from a single to double linking (*Chem. News* Jan. 1906); possibility of stereo-isomerism which is shown by a divergence in b.-p. detns. and by slight differences in titrating with  $\text{NaOH}$  or  $\text{Ca(OH)}_2$ , since the normal Na salt is slightly alk. while the Ca salt is neutral;  $\text{AcOH}$  of max. d. is formed by a union of 67.7 parts of acid with 18 of  $\text{H}_2\text{O}$ , but with a hydrate,  $\text{C}_2\text{H}_4\text{O}_2 \cdot \text{H}_2\text{O}$ , the ratio would be 60:18. The possible persistence of the double

structure of  $\text{Ac}_2\text{O}$ ,  $\begin{array}{c} \text{Me}-\text{CO} \\ \diagdown \quad \diagup \\ \text{O} \\ \diagup \quad \diagdown \\ \text{Me}-\text{CO} \end{array}$ , in the mol. of  $\text{AcOH}$  may be due to the fact that its d.

is almost identical with the max. for  $\text{AcOH}$ .

C. H. KIDWELL.

**The manufacture of synthetic acetic acid and other organic chemicals in Canada.** ANON. *Can. Chem. J.* 3, 56-7(1919).—The Canadian Electro Products Co., Ltd., at Shawinigan Falls, Que., has erected 2 plants each having a capacity of approx. 700-800 gross tons glacial  $\text{AcOH}$  per month by the following process: 1. Conversion of  $\text{C}_2\text{H}_2$  to  $\text{MeCHO}$  in the presence of  $\text{H}_2\text{SO}_4$  and a Hg salt. 2. Conversion of the  $\text{MeCHO}$  to  $\text{AcOH}$  by oxidation in the presence of a catalyzer. 3. Catalytic decompn. of glacial  $\text{AcOH}$  into  $\text{Me}_2\text{CO}$ . Only pure products are used for each successive step, glacial  $\text{AcOH}$  of over 99% thus being obtained on the first run. This  $\text{AcOH}$  is free from  $\text{H}_2\text{SO}_4$ , tar, and resinous matter and is water-white, a great advantage in the manuf. of colors. It is possible that alc.,  $\text{Ac}_2\text{O}$ ,  $\text{C}_2\text{H}_2\text{Cl}_2$ ,  $\text{CCl}_3\text{CH(OH)}_2$ ,  $\text{CHCl}_3$ ,  $\text{C}_2\text{H}_2\text{Cl}_2$ ,  $\text{AcOEt}$ ,  $\text{HCHO}$ ,  $\text{CH}_2\text{ClCO}_2\text{H}$ , and  $(\text{C}_2\text{H}_4\text{O})_2$ , may be manufd. at the same plant. C. H. K.

**Intramolecular wandering of the phenyl group.** P. J. MONTAGNE. *Leyden. Chem. Weekblad* 15, 1195-204(1918); cf. *C. A.* 13, 730. JULIAN F. SMITH.

**The reduction products of hydroxymethylenecamphor.** I. H. RUPE, A. AKERMANN AND H. TAKAGI. *Basel. Helvetica Chim. Acta* 1, 452-72(1918).—The attempts of Kötzt and Schaeffer (*C. A.* 6, 2757; 8, 1094) to prep. keto alcs. by reducing hydroxymethylene compds. in presence of colloidal Pd or Pt yielded chiefly Me ketones. By using Ni as the catalyst, however, a smooth reduction to the keto alc. is possible. Ni pptd. on various carriers, as recommended by Kelber (*C. A.* 10, 897), gives unsatisfactory results. The best reductions are obtained with a catalyst made by pptg. Ni on finely powdered clay (made from porous plates). This powder, containing about 33% of Ni, can be kept for months in a sealed tube, in an atm. of  $\text{CO}_2$ , with very little deterioration. The hydrogenation of hydroxymethylene-camphor (A) is best carried out at slightly more than 1 atm. pressure. The substance is dissolved in 10 parts by wt. of  $\text{EtOH}$ , or in dil.  $\text{NaOH}$ . When  $\text{EtOH}$  is used, part of it is reduced to  $\text{MeCHO}$ . The velocity of reduction depends on the amt. of catalyst, being much greater if the ratio of catalyst to substance is 2:1 than if it is 1:1. As a rule the absorption of H ceases before the calcd. amt. is used, partly because some absorption occurs while replacing the  $\text{CO}_2$  in the reduction chamber with H, and partly because of the decompn. of  $\text{H}_2\text{O}$  by the Ni. Very little unchanged (A) is left. The absorption curve rises rapidly to the point of complete hydrogenation, where it suddenly becomes almost horizontal. Slight amts. of Cu, or larger amts. of  $\text{Fe}^{2+}$ , poison the catalyst, but  $\text{Fe}^{3+}$  does not. The yield of camphylcarbinol (B) varies from 80 to 95% of the theoretical, the remainder being chiefly methylenecamphor (C) and other low boiling substances. Purification is best effected by means of the  $\text{CaCl}_2$  compd., which is powdered and washed thoroughly with  $\text{PhH}$ , then decompd. with  $\text{H}_2\text{O}$ , yielding pure (C), b.  $138-41^{\circ}$ . The  $\text{HBr}$  ester (camphylbromomethane), m.  $65.5-66^{\circ}$ , is obtained with 96% yield by treating with 1.5 mols. of  $\text{PBr}_3$  at about  $0^{\circ}$ . When treated with moist  $\text{Ag}_2\text{O}$  it yields (B), but the

yield is low. The HCl ester, m.  $53-4^{\circ}$ ,  $b_{14}$   $125-7^{\circ}$ , is obtained, with 80% yield, by treatment with  $\text{SOCl}_2$ . When prepd. by passing dry HCl into liquid (B), the yield is only 55%. Oxidation of (B) with an excess of  $\text{CrO}_3$  gives up to 50% yields of camphorquinone, m.  $197^{\circ}$ , and a mobile oil,  $b_{10}$   $125-30^{\circ}$ , which is not an aldehyde. No (A) is formed. Though camphoraldehyde has not yet been prepd. by oxidation of (B), the suggestion is made that it is probably formed and immediately rearranges to (A), which is then oxidized to camphorquinone; or, less probably, it may be oxidized to the  $\text{CO}_2\text{H}$  acid and then to the quinone. Oxidation with  $\text{MnO}_2$  in  $\text{H}_2\text{SO}_4$  yields very small amts. of a compd., m.  $201^{\circ}$ , having 76.44% C and 8.78% H. No camphorquinone is formed. Comparison of the optical properties of (B) after purification by distn., by means of the  $\text{CaCl}_2$  compd., and by esterification with  $\text{BzCl}$  and sapon., gave evidence that only the last named method yields optically pure (B); the values of  $[\alpha]_D^{20}$  are consistently somewhat higher than for samples prepd. by the first 2 methods. All 3, however, give samples having the same sp. gr. ( $d_4^{20}$  1.0502) and b. p. ( $b_9$   $138-41^{\circ}$ ). The purification by means of the Bz ester is unexpectedly difficult. The ester can be obtained, with 98% yield, by esterification with  $\text{BzCl}$  in  $\text{C}_6\text{H}_6\text{N}$ ; but sapon. with alc. KOH yields only (C), owing to dehydration of (B) as fast as formed. Other alk. sapon. agents give the same results. Acids react very slowly, with partial dehydration of (B), and give very low yields. Phthalic anhydride does not esterify (B); the product of the reaction is (C). The formyl ester, however, can be obtained in quant. yield by esterifying with 86%  $\text{CH}_2\text{O}_2$ . From dil. EtOH it forms long, silky needles, m.  $74-5^{\circ}$ ,  $b_{11}$   $142-3^{\circ}$ . In view of the dehydrating power of  $\text{CH}_2\text{O}_2$ , this easy prepn. is unexpected; but (B) seems to be peculiarly susceptible to dehydration by alk. rather than acid agents. Similar success is possible with the Ac ester, which is a colorless, mobile liquid of pleasant odor,  $b_{10}$   $148.5-49^{\circ}$ . As by-products of the hydrogenation of (A), the following substances are formed: (I) (C),  $b_{10}$   $82-4^{\circ}$ , m. slowly about  $40^{\circ}$  (impure). The crude substance yields the pure hydrobromide, m.  $65-6^{\circ}$ , and dibromide, m.  $108-9^{\circ}$ . Pure (C) can be prepd. by treating the hydrobromide, or better still (B), with KOH in MeOH. The substance described by Minguin (*Compt. rend.* 136, 752(1903)) is repeatedly described in the literature as pure, but it was not. Pure (C), m.  $43.5-44^{\circ}$ , congeals when cooled to  $35-30^{\circ}$  to a white, waxy mass. Its odor is like that of camphor, but less pleasant. It is so sol. that no solvent has been found from which it can be recrystd. When distd. repeatedly *in vacuo*, it polymerizes slowly. (II) Methylcamphor, recovered from the filtrates after treating (C) with HBr, or prepd. by reduction of (C) (yield quant.). It is a camphor-like solid, m.  $37.5-8.5^{\circ}$ ,  $b_{10.5}$   $90-1^{\circ}$ ,  $b_{11}$   $88-9^{\circ}$ . (III) The Et ether of (B), and (IV) the Et ether of (A), formed by condensation with the EtOH used as solvent. No optical isomer of (B) has yet been isolated. JULIAN F. SMITH.

**Constitution of strychnine.** Preliminary note. L. REUTTER. Geneva. *Schweiz. Apoth.-Ztg.* 56, 650-1(1918).—Strychnine (100 g.) was dry-distd. with 1 kg. Zn dust under reduced pressure. The distillate was aq., then oily, recalling the odor of pyridine and conicine. The distn. residue was successively extd. with  $\text{Et}_2\text{O}$ , EtOH,  $\text{CHCl}_3$ . After distg. off the solvents, the united extn. residues were in part subjected to fractional distn., yielding apparently indole, pyridine, conicine and quinoline. In another part a mixt. of bases was isolated by means of dil. HCl, NaOH and  $\text{Et}_2\text{O}$ ; these bases were fractionated. In the fraction  $110-30^{\circ}$ ,  $\text{C}_8\text{H}_9\text{N}$  was identified by its b. p. and the m. p. of the picrate and chloroplatinate. Between  $130$  and  $150^{\circ}$ , picoline and lutidine were probably present; between  $150$  and  $190^{\circ}$  conicine was identified (C and H detns. and b. p.; m. p. of the HCl salt and aurate). The fraction  $200-250^{\circ}$  contained quinoline. S. WALDBORT.

**Thienylquinolinecarboxylic acid.** MAX HARTMANN AND ERNST WYBERT. Soc. Chem. Ind., Basel. *Helvetica Chimica Acta* 2, 60-3(1919).—The purpose of the

investigation was to det. the influence of a substitution of the thiophene group for the Ph group in the cinchoninic acid mol. H. and W. find that this substitution increases the antiphlogistic and analgesic properties and that a peculiar side effect is produced when the new S compound as an acid or an ester is administered to animals by feeding the acid or by injection of a sol. salt into the blood. The animal shortly assumes a violet color and the urine is colored a deep permanganate which persists for a very long time; the color spreads to nearly all internal organs. This coloring matter was isolated from the urine in good yields but its constitution remains unknown. H. and W. believe this coloring matter to be produced within the animal through oxidation and subsequent condensation with unknown substances of animal origin. The production of the same coloring matter from the S compd. *in vitro* was not accomplished even when treated with enzymes or sections from various organs. *2-Thiënnylquinoline-4-carboxylic acid* is prepd. by heating on a water bath with stirring for three hrs. a mixt. of 80 g. acetothienone, 88 g. isatin, 470 cc. 28% KOH and 70 cc. alc.; on cooling the acid is pptd. with AcOH and recrystd. from alc.; yellow crystals, m. 211°; slightly sol. in H<sub>2</sub>O; fairly sol. in hot alc.; sol. in alkalis with pptn. by dil. acids; sol. in excess of concd. acids. Variation in crystn. gives either colorless or yellow crystals of the same m. p. An ester, m. 83° is prepd. from EtOH and HCl; the salts are very sol. in H<sub>2</sub>O with neutral reaction. The violet coloring matter in the urine was obtained by adding a large vol. of slightly acidified alc., filtering and evapg. to dryness and recrystg. from alc.; it is sol. in alkalis, forming brown salts.

N. A. LANGE.

**Hydroxycarbonyl compounds. I. A new synthesis of hydroxyaldehydes.** P. KARRER. Univ. Zurich. *Helvetica Chimica Acta* 2, 89-94(1919).—The interaction of CNBr and polyhydric phenols in the presence of HCl produces aldehydes in good yields but does not produce carboxylic acids nor ketones, as might be expected from the similarity of this reaction to the Gattermann aldehyde synthesis. K.'s method is better than G.'s because CNBr can be employed in place of the dangerous dry HCN and since the yields are good K. believes it will replace the older method for the prepn. of this class of compds. *2,4-Dihydroxybenzaldehyde*. (A) A rapid stream of dry HCl was passed for several hrs. into a soln. of 10 g. resorcinol (B), 150 cc. abs. Et<sub>2</sub>O, 3 g. anhydrous ZnCl<sub>2</sub>, 5 g. CNBr. Crystals appear after several hrs. and the reaction mixt. is allowed to stand overnight; these crystals are an intermediate compound (C) of the probable constitution  $\text{C}(\text{OH})\text{:C}(\text{OH})\text{:CH.CH:NCl}$ . After decanting

the Et<sub>2</sub>O, the crystals (C) are washed with abs. Et<sub>2</sub>O, dissolved in H<sub>2</sub>O and the aq. soln. is extd. with Et<sub>2</sub>O to remove (B). The aq. soln. is boiled 20 min. and then extd. with Et<sub>2</sub>O; the dried Et<sub>2</sub>O ext. is evapd.; the residue is recrystd. from Et<sub>2</sub>O by addition of ligroin when (A) is obtained. Phloroglucinaldehyde was obtained in a similar manner when phloroglucinol.

N. A. LANGE.

**Ring formation with the loss of a nitro group.** S. REICH AND MILE. V. NICOLAEVA. Org. Chem. Lab., Geneva. *Helvetica Chimica Acta* 2, 84-8(1919).—*2,4-Dinitroacetophenone oxime* (A). A soln. of equimol. proportions of dinitroethylbenzene and Am nitrate in abs. alc. is cooled to 0° and Na alcoholate is gradually added. The soln. turns brown and a brown ppt. forms. After several hrs. it is treated with H<sub>2</sub>O, filtered, and the oxide is pptd. by acidifying the filtrate. After repeated crystns. from alc. (A) is obtained in yellow prisms, m. 124°. (A) is heated for 1/4 hr. with 15% HCl; H<sub>2</sub>O is added, and the soln. extd. with Et<sub>2</sub>O. The Et<sub>2</sub>O is dried with CaCl<sub>2</sub> and distd., the ketone *2,4-dinitroacetophenone* (B) forming an oily yellow liquid which does not solidify after 3 months. (B) forms a *phenylhydrazane*, red-brown clusters from alc., m. 165-6°. When (B) in alc. is treated with cold. aq. KOH, the original red soln. changes to blue,

then green and finally yellow; upon addition of  $\text{H}_2\text{O}$  methylphenylnitroisindazole (I) is pptd.; recrystd. from dil. alc. it is obtained in yellow crystals, m.  $139-40^\circ$ . Among the 3 by-products in the prepn. of (A) is a methylnitroindoxazine (II). This is sepd

from the other two by fractional crystn. from alc.; it is obtained in largest quantity and m.  $114^\circ$ . The other two components m.  $200^\circ$  and  $63^\circ$ ; they were not further investigated. N. A. LANGE.

**Action of magnesium and zinc on dichloromethylarsine.** ENRIQUE V. ZAPPI. Chem. Inst., Buenos Aires. *Bull. soc. chim.* 23, 322-4 (1918).—1 mol.  $\text{MeAsCl}_2$  and 2 mols. Mg were boiled 3 hrs. in 25 cc. anhydrous  $\text{Et}_2\text{O}$  under a cold reflux. 1 part of the  $\text{Et}_2\text{O}$ , upon evapn., left a residue of  $\text{MeAsCl}_2$  which was not decompd. by addition of 1 part  $\text{H}_2\text{O}$ . But the part remaining in the flask with the Mg was decompd. rapidly by  $\text{H}_2\text{O}$  with the production of an As-contg. gas. To 1 mol. granular Mg and 1 mol.  $\text{MeAsCl}_2$ , contained in a flask fitted with a Br tube and a tube to collect the gas,  $\text{H}_2\text{O}$  was added through the Br tube. A violent reaction occurred yielding a gas (A), a red substance (B) and an aq. residue (C). (A) was a colorless gas, insol. in  $\text{H}_2\text{O}$ , which burned with production of  $\text{CO}_2$ , oxidized in air producing white fumes, reduced  $\text{NH}_3$ - $\text{AgNO}_3$  and HI; it was absorbed by  $\text{HNO}_3$ , the soln. giving the reactions of  $\text{H}_2\text{AsO}_4$ , although the residue from the evapn. of the  $\text{HNO}_3$  soln. gave the reactions of  $\text{MeH}_2\text{AsO}_4$ . The per cent. compn. of the mixed gas was:  $\text{MeAsH}_2$ , 33;  $\text{H}_2$ , 60;  $\text{CH}_4$ , 2.6;  $\text{N}_2$ , 4. The presence of the last 3 gases is due to the action of small amts. of  $\text{O}_2$  getting into the flask. (B), filtered from (C) and boiled with  $\text{H}_2\text{O}$  acidified with  $\text{H}_2\text{SO}_4$  to remove excess Mg, washed with  $\text{H}_2\text{O}$  and dried over  $\text{H}_2\text{SO}_4$ , changed slowly from red to violet in color. It had a nauseating odor, melted and volatilized, giving  $\text{As}_2\text{O}_3$  fumes without leaving a residue; it was ignited when dropped into boiling  $\text{HNO}_3$  and the soln., evapd., left a residue possessing the reactions of an acid of  $\text{MeH}_2\text{AsO}_4$ , and not those of  $\text{H}_2\text{AsO}_4$ . Analysis showed it to be MeAs. (C) contained  $\text{MgCl}_2$  and did not give the reactions of  $\text{H}_2\text{AsO}_4$ . These results show that Mg does not act directly on  $\text{MeAsCl}_2$  in the presence of anhydrous  $\text{Et}_2\text{O}$  and is not capable of forming a Mg deriv. In the presence of  $\text{H}_2\text{O}$  there is a violent reaction with the formation of  $\text{MeAsH}_2$ ,  $\text{H}_2$ ,  $\text{CH}_4$  and pptn. of  $(\text{CH}_3\text{As})_x$ . Zn is capable of producing the same reactions. C. H. KIDWELL.

**Synthesis of alcohols in the thiophene series.** V. THOMAS AND V. COUDERC. Clermont-Ferrand. *Bull. soc. chim.* 23, 326-8 (1918).—T. has shown that  $\text{C}_4\text{H}_5\text{SI}$  reacts with Mg, forming organo-Mg compds. possessing the general properties of those of the  $\text{C}_4\text{H}_5$  series (*Bull. soc. chim.* 5, 730). The  $\text{C}_4\text{H}_5\text{SMgI}$  is employed here to react with ketones in the prepn. of alcs. of the  $\text{C}_4\text{H}_5\text{S}$  series. It reacts with  $\text{Ph}_3\text{CO}$ , forming diphenylthienylcarbinol,  $\text{Ph}_2\text{C}(\text{OH})\text{C}_4\text{H}_5\text{S}$ , which is also obtained by condensation of  $\text{PhMgI}$  with  $\text{PhCOC}_4\text{H}_5\text{S}$  (72% yield).  $\text{C}_4\text{H}_5\text{SMgI}$  appears to condense with the  $\text{PhNH}_2\cdot\text{HCl}$  in  $\text{AcOH}$  to form colorless leaflets which are being studied.  $(\text{C}_4\text{H}_5\text{S})_2\text{C}(\text{OH})\text{Ph}$  results by condensing  $\text{C}_4\text{H}_5\text{SCOPh}$  with  $\text{C}_4\text{H}_5\text{SMgI}$ . A compd. m.  $90^\circ$  can also be isolated, hexagonal lamellae or large, prismatic needles; alters in air and light more easily than the  $(\text{C}_4\text{H}_5\text{S})_2\text{C}(\text{OH})\text{Ph}$  but both compds. dissolve in  $\text{H}_2\text{SO}_4$ ,  $\text{HNO}_3$  and  $\text{HCl}$  to a brown soln. not produced by  $\text{AcOH}$  and  $\text{Me}(\text{CH}_2)_3\text{CO}_2\text{H}$ .  $(\text{C}_4\text{H}_5\text{S})_2\text{C}(\text{OH})\text{Ph}$  is sol. in alc.,  $\text{Et}_2\text{O}$  and benzene; insol. in  $\text{H}_2\text{O}$ ; 50% yield.  $\text{C}_4\text{H}_5\text{SMgI}$ , prepd. with  $1/8$  mol.  $\text{C}_4\text{H}_5\text{SI}$  and  $7/8$  mol. Mg, was condensed with  $1/8$  mol.  $(\text{PhCO})_2$ . Upon evapn.

a brown, resinous material appeared which yielded by steam distn. colorless needles m.  $56^{\circ}$ . By the same method, the wash  $H_2O$  yielded the same product; long, colorless needles, m.  $56^{\circ}$ , were obtained by soln. in alc. and purification with animal charcoal. Although its constitution has not been detd., the compd. is probably thienylphenylbenzoin,  $Ph(C_6H_5S)C(OH)COPh$ ; calcd. mol. wt. 294; found, 285.

C. H. KIDWELL.

Some derivatives of isatin. ANDRÉ MEYER. *Compt. rend.* 167, 1070-3(1918).—Knorr (*Ann.* 238, 192) obtained, by oxidation of aminophenylmethylpyrazolone, a dark red compd., rubazonic acid. M. has investigated a series of rubazonic acids derived from phenylisoxazolone (*C. A.* 5, 3224). Baeyer and Knop (*Ann.* 140, 37) observed a fuchsin-red color, reflecting green, as an intermediate step during the synthesis of isatin by reduction of isonitroso-oxindol and further oxidation of amino-oxindol. On oxidation with air of the product of the reduction of nitroso- $\gamma$ -hydroxycarboxystyryl, Baeyer and Homolka (*Ber.* 16, 2219) noted a dark blue indigo ppt. The purpose of this investigation is to study the nature of such products. Isatoxime, reduced by Sn and concd. HCl until the soln. was decolorized, the soln. then being filtered and evapd. at a low temp. to drive off excess HCl, yielded the amino-oxindol chlorostannate, colorless leaf-like crystals, after crystn. from dil. HCl. The chlorostannate, decompd. by  $H_2S$ , furnished a soln. of the hydrochloride which turned red in the air and from which the salt was isolated by concn. *in vacuo*. The acidity of the soln. was detd. by titration and sufficient alkali was added to liberate the amine. When oxidation was carried out by a calcd. amt. of  $K_2Fe(CN)_6$ , only a small yield of red ppt. was obtained, a large amt. of the amino-oxindol being converted into isatin. Reduction of the red compd. by  $Na_2S_2O_4$  in a strong alk. medium, and warming, gave a yellow soln.  $H_2SO_4$  dissolved the compd.; the red soln. decomposed on diln. with the formation of a yellow color. Concd. alkali produced a violet color. Isatoxime, reduced with AcOH and Zn, yielded a dark red color, reflecting green, from which dark red crystals pptd. This compd., washed with dil. AcOH and  $H_2O$  and recrystd. from alc. and AcOH, was  $C_{16}H_{10}O_2N_2Zn$ , the salt of an isomer of indigo,  $C_{16}H_{10}O_2N_2$ . It gave a violet color with concd.  $H_2SO_4$ , dissolving to orange-red; on diln. and warming it was hydrolyzed to produce a brown soln.  $Na_2S_2O_4$  in an alk. medium dissolved it, forming a brown soln. These characteristics indicate that the compd. acts here as the indine of Laurent (*Ann. chim. phys.* [3] 3, 471), which is probably identical with the iso-indigotin of Wahl and Bagard (*Bull. soc. chim.* 5, 1039). Some mixed rubazonic acids of the isatin series were prepd. by condensing, in alc., aminoantipyrine with isatin, 5-bromisatin, 5,7-dibromisatin and naphthisatin. These red compds., sol. in  $H_2SO_4$  with dark violet color, hydrolyzable in dil. acids, insol. in  $H_2O$  and slightly sol. in organic solvents, are of the general type:

X representing the substituted  $C_6H_5$  or  $C_{10}H_7$  nucleus.  $C_6H_4.CH.NH_2.CO.NH$  cannot

be diazotized, thus behaving as a substituted benzylamine, not as a heterocyclic amine. It condenses with aromatic aldehydes.

C. H. KIDWELL.

New salts of *As-dimethylarsepedine*. ENRIQUE V. ZAPPI AND JUAN L. LANDABURU. *Chem. Inst., Buenos Aires. Bull. soc. chim.* 23, 324-6(1918).—The prepn. of these salts was accomplished by the satn. of a soln. of the hydrate of *As-dimethylarsepedine* (*C. A.* 10, 2874) with the acid of which a salt was desired. The resulting soln. was evapd. over  $H_2SO_4$ , then solid NaOH and finally over  $P_2O_5$ . Vacuum was not used since it partially decomp. the salts. *As-Methylarsepedine methochlo-*

ride,  $\text{CH}_3 \begin{array}{c} \text{CH}_3-\text{CH}_2 \\ \text{CH}_2-\text{CH}_3 \end{array} \text{As} \begin{array}{c} \text{CH}_3 \\ \text{CH}_3 \\ \text{Cl} \end{array}$ , is a white, odorless cryst. solid, m.  $237^\circ$  (decompn.),

very hygroscopic, forms a neutral soln. in  $\text{H}_2\text{O}$  possessing characteristic Cl reactions. The corresponding *bromine compound*,  $\text{C}_7\text{H}_{13}\text{AsBr}$ , is a white solid, somewhat hygroscopic, m.  $277-80^\circ$  (decompn.), giving a neutral soln. possessing the reactions of Br. The *sulfate*,  $(\text{C}_6\text{H}_{13}\text{AsMe}_2)_2\text{SO}_4$ , is an odorless, slightly hygroscopic white solid, m.  $232^\circ$  (decompn.), whose  $\text{H}_2\text{O}$  soln. is neutral to litmus and ppts. with Ba salts. The *nitrate*,  $\text{C}_7\text{H}_{13}\text{NO}_2\text{As}$ , is a hygroscopic light brown solid, m.  $260^\circ$  (not sharp); its soln., reduced by  $\text{H}_2\text{SO}_4$  and Zn, liberates the N as  $\text{NH}_3$ . By passing  $\text{CO}_2$  into a soln. of arsenic dimethylarsenedine, the alkalinity of the hydrate is lost to phenolphthalein but not to litmus. When this soln., which contains the carbonate,  $\text{C}_6\text{H}_{13}\text{AsMe}_2\text{CO}_2\text{H}$ , was evapd. over  $\text{P}_2\text{O}_5$  it left a dirty white residue with the disagreeable odor of methylarsenedine. The carbonate, m.  $156-7^\circ$  (decompn.), is very hygroscopic; its soln. is decompd. by acids with evolution of  $\text{CO}_2$  and ppts. Ag and Fe salts. C. H. KIDWELL.

**Synthetic camphor.** ANDRÉ DUBOSC. *Rev. prod. chim.* 21, 369-72 (1918).—A general review of the various methods available for the prepn. of synthetic camphor. No new facts are presented. M. P.

Silver-asbestos, lead chromate-asbestos and lead peroxide-asbestos for use in combustions (BINDER) 7. Acetone (BASSETT) 22. Determination of halogens in organic compounds (BUSCH) 7. Sapidity and stereoisomerism (BARRAL, RANC) 11H.

BAUER, RUDOLF AND WIELAND, H.: *Reduktion und Hydrierung organischer Verbindungen*. Leipzig: Otto Spamer. 324 pp. M. 20. For review see *Chem. Weekblad* 16, 185 (1919).

**Toluenesulfonic acids.** J. A. AMBLER and H. D. GIBBS. U. S. 1,292,950, Jan. 28. Toluenesulfonic acids are made continuously by passing vapors of toluene into contact with a descending current of  $\text{H}_2\text{SO}_4$  in a reaction tower. The pat. is "dedicated to the public" for free use without payment of royalty.

**Rectifying alcohol.** E. A. BARRET. U. S. 1,292,676, Jan. 28. Concd. alc. is obtained from fermented alc. liquid by heating the liquid sufficiently to drive off first runnings as vapors, and rectifying these first runnings by fractional condensation, heating the liquid from which the first runnings have been removed sufficiently to vaporize all the alc. which it contains, rectifying the alc. vapors thus produced together with the alc. condensate from the rectification of the vaporized first runnings, and withdrawing separately the alc. condensate from the rectification of the combined alc. vapors.

**Trinitrophenol and trinitrocresol.** RASIK LAL DATTA and PHULDEO SAHAY VARMA. U. S. 1,292,266, Jan. 21. Trinitro derivs. of phenol or cresol are produced by reacting upon phenol- or cresolsulfonic acid with nitrous gases such as the mixt. of  $\text{N}_2\text{O}_4$  and  $\text{N}_2\text{O}$  produced by the oxidation of N in an elec. arc furnace. A soln. of the pure trinitro compd. is obtained, except for the presence of a small amt. of  $\text{H}_2\text{SO}_4$  produced in the reaction. No charring or blackening of the product takes place.

**Urea.** K. NIKRISHNEM, C. BOSCH and A. MITTASCH. U. S. 1,292,019, Jan. 21.  $\text{NH}_4$  carbamate, mixed with 5% of  $\text{K}_2\text{CO}_3$  or 3% of  $(\text{NH}_4)_2\text{SO}_4$ , is heated under pressure to  $135-40^\circ$ . Formation of urea takes place more quickly than with  $\text{NH}_4$  carbamate alone. Other  $\text{NH}_4$  salts may be used, e. g., selenite, chloride, acetate, oxalate or citrate, and other salts also (e. g.,  $\text{Na}_2\text{SO}_4$ ,  $\text{Na}_2\text{S}$ , Na formate or

$\text{CaCl}_2$ ), may serve as catalysts. After the reaction, the urea may be freed from the catalytic salts by dissolving it in alc. A small quantity of  $\text{H}_2\text{O}$  or of  $(\text{NH}_4)_2\text{CO}_3$  may be added, as promoters of the reaction.

## II. BIOLOGICAL CHEMISTRY.

HATTIE L. HEFT AND WILLIAM J. GIES.

### A. GENERAL.

FRANK P. UNDERHILL.

**Value of modern chemistry.** JOHN G. WURTZ. *Hahnemannian Monthly* 53, 740-7(1918).—A summary of recent researches on the chemistry of the blood and urine, and their clinical application. JOSEPH S. HEPBURN.

**Technic for following the progress of proteolysis in a "gelatin-trypsin" medium.** L. LAUNOY. *Compt. rend. soc. biol.* 81, 742-4(1918).—The action of trypsin on a litmus-gelatin medium neutral to litmus results in an acid reaction within 1 hr. at  $41^\circ$ . The acidity increases rapidly until the 4th hr. of digestion, when it attains a concn. capable of retarding enzymic action; the acidity then increases slowly. The acidity is a good index of the rate of tryptic action. Production of acidity is at first more rapid in gelatin neutral to phenolphthalein than in gelatin neutral to litmus; the final result is the same in both cases. The action of trypsin results in the formation of certain acid substances (the identity of which is unknown) which may be titrated directly with NaOH; in addition, amino acids are produced, the acidity of the latter being titratable after action of formol (Sørensen method). In a "gelatin-trypsin" medium neutral to litmus the acidity liberated by formol is, during the first few hrs. of digestion, distinctly less than that of the acid substances above mentioned; the respective curves first diverge, then become parallel, approach each other, and finally cross at approx. the 30th hr. of digestion. Practically identical results were obtained with gelatin dialyzed 7 days as with undialyzed gelatin; the acidity produced during digestion cannot, therefore, be due to pre-existent compds. such as acids and acid salts which escaped neutralization and were then liberated by tryptic action. It is possible that these acid substances may be of the nature of the acid peptones studied by Siegfried and Krüger. This method of following the course of tryptic action by titration of the acidity produced may be applied to detn. of the antitryptic power of blood serum; in this case the serum and trypsin are added to gelatin which is neutral to litmus.

H. S. PAINE.

**Catalytic action of serpents' venom upon nucleic acids.** C. DELEZENNE AND H. MOREL. *Compt. rend.* 168, 244-6(1919); cf. *C. A.* 5, 1943, 3093; 7, 1752; 8, 3591.—Nucleic acids from beer yeast and from animal thymus were prepd. in as pure form as possible and made into the Na salts. These were dissolved in a concn. of 1 to 2% in a 9% soln. of salt water and the solns. made strictly neutral to phenolphthalein. To these were added variable amts. of venom from serpents of the families Colubridae and Viperidae made into 1% strength in physiol. saline. All manipulations were made in a manner to favor sterility of the mixts., and the latter were placed in a thermostat at  $50^\circ$  for varying lengths of time. The results showed that the nucleic acids were hydrolyzed by the venom. The cobra venom, which was most active, caused the nucleate rapidly to lose the property of being pptd. by HCl. Thymonucleate, which gelatinizes readily, remains liquid or gelatinizes slowly after being acted upon by the venom. The liquid medium becomes acid to both phenolphthalein and tournesol due to the liberation of  $\text{H}_2\text{PO}_4$ , the progress of the reaction being detd. by titration with NaOH. Acidity which at first increases rapidly with the time later augments more

slowly, the reaction being of a diastatic type. On the other hand small amts. of venom develop the same acidity with the time as large amts., there being no relation between amts. of material transformed and the quantity of venom utilized. There is no action at 0°; it is slow at ordinary temps.; the optimum temp. is 50 to 52°. The venom loses its hydrolyzing properties by being heated a few min. at 100°. The activity of the venom is totally destroyed by the addition to the medium of a specific antivenomous serum. The more toxic the venom the greater is its hydrolyzing power.

L. W. RIGGS.

**Biological reactions of the species and parasitic specificity.** J. DUFRÉNOY. *Rev. gén. sci.* 30, 44-7(1919).—Parasitic specificity and the resistance of the hosts are characters which, although relative, are rather stable, permanent, hereditary and depend immediately upon no one ecologic factor. It is important to exterminate the receptive hosts which perpetuate the parasite, resulting in massive infections. The parasites which form with their hosts a durable syntrophic association, appear with a specific exigence such that they separate into physiologically racial groups, the more pronounced into morphologic groups. Accordingly these parasites show the best reactions for the purpose of defining their specific groupings and the phyletic relations of the different species. The work of Stakman (Univ. Minnesota) is freely quoted. L. W. RIGGS.

## B. METHODS AND APPARATUS.

STANLEY R. BENEDICT.

A method for the determination of fat in dried feces and its distribution as soap, free fatty acids and neutral fat. An application to feces of the Roesse-Gottlieb method for determining fat in dried and condensed milks. L. E. HOLT, A. M. COURTNEY AND H. L. FALES. *Am. J. Dis. Children* 17, 38-42(1919).—A sample of thoroughly dried and powdered feces is treated with dil. HCl on the water bath until well heated and disintegrated. The mixt. is transferred to a Roehrig tube and extd. with Et<sub>2</sub>O and petrol. ether. The residue from these exts. gives the total fat. Another sample is disintegrated with water before extg., giving neutral fat and free fatty acids. The difference between these detns. gives the soaps. The ext. from the non-acidified sample is dissolved in benzene and titrated while very hot with alc. NaOH, using phenolphthalein as indicator. The NaOH soln. is standardized with stearic acid. This gives the free fatty acids.

S. AMBERG.

Sudan III and the detection of fat. V. H. MORTRAM. *Proc. Physiol. Soc., J. Physiol.* 52, xviii(1918).—It is proposed to use Sudan III as a qual. test for fats as follows: 1 g. powdered solid is shaken with 10 cc. satd. soln. of Sudan III in 70% alc. for 1 min. The fluid is filtered off through a small fat-free paper and the color of the resultant soln. compared with that of a control. The control is prepd. by shaking 1 g. of a fat-free powder (*e. g.*, starch or casein) with Sudan III soln. and treating as above. When the tested-solid contains more than 0.04 g. of fat the Sudan III filtrate is markedly lighter in color than the control. It is thought that in some cases the test might be quant.

J. F. LYMAN.

A promising chemical photometer for plant physiological research. CHARLES S. RIDGWAY. *Mo. Weather Rev.* 46, 117-9(1918).—The method proposed by Bacon (*C. A.* 5, 1360) was used. The oxalic acid decompd. by light in the presence of U salts was detd. by titrating the undecompd. acid with 2 N KMnO<sub>4</sub>. It was found un-

necessary to ppt. the U before titration. A mixt. of 5 cc. of 1% U acetate and 20 cc. of 5% oxalic acid in a 100 cc. Florence flask was placed so that only its surface was exposed to light. Comparisons were made with the Callender recording pyrheliometer. The mean ratio, cal. recorded by the pyrheliometer to g. oxalic acid decomposed, was 978. In 9 cases the deviation from the mean ranged between 0.2% and 3% on either side. Greater variations in 4 cases were thought to be due to the occurrence of clouds or haze which affected the intensity of the rays at one end of the spectrum to a greater extent than those at the other end, or to intermittent cloudiness which made it impossible to evaluate the pyrheliometer record accurately. The chem. photometer probably shows the effect of light belonging chiefly to the violet end of the spectrum. No decompn. of the oxalic acid occurs in the dark in 3 days. In the diffuse light of the lab. several hrs. exposure are necessary before measurable decompn. results. The temp. coeff. over a wide range is negligible. R. considers that the simplicity and accuracy of the method should make it useful for plant physiological work. J. G. PHILLIPS.

**Detection of quinine in urine.** MEYER. *Pharm. Ztg.* 1918, 49; *Schweiz. Apoth. Ztg.* 56, 609(1918).—Add to urine  $(\text{NH}_4)_2\text{CO}_3$  in excess and  $\text{MgSO}_4$  ppt. with tannic acid, filter, set free quinine by  $\text{Ca}(\text{OH})_2$  on the water bath. Filter, dissolve all the quinine by washing with hot  $\text{H}_2\text{O} + \text{NH}_4\text{OH}$ , ext. the quinine in the filtrate by shaking with  $\text{Et}_2\text{O}$ . Evap. and weigh. S. WALDBOTT.

**Determination of fructose in presence of aldoses (HERZFELD, LENART) 7.**

MCJUNKIN, F. A.: **Clinical Microscopy and Chemistry.** Philadelphia: W. B. Saunders Co. 470 pp. \$3.50. For review see *J. Am. Med. Assoc.* 72, 819(1919).

### C. BACTERIOLOGY.

**A biochemical study of the plankton of Lake Mendota.** H. A. SCHUETTE. *Trans. Wis. Acad. Sci., Arts, and Letters* 19, 594-613(1918).—This is the first record, the author says, of a chem. examn. of composite catches of fresh-water plankton. The nature of the catch depends largely upon meteorological conditions, and the chem. compn. varies with the proportions of plant and animal forms. Data are given for ash,  $\text{SiO}_2$ ,  $(\text{CH}_3)_2\text{O}$  ext., physical and chem. constns. of oils, crude fiber, N in crude fiber, total S, total P, total N, protein N, non-protein N, N as  $\text{NH}_3$ , diamino N, monoamino N and "humic" N. Qual. tests showed small amts. of reducing sugars. All samples gave measurable amts. of furfural, but the amts. do not vary enough with vegetable and animal forms to apply detn. of pentosans as a means of estg. proportions of vegetable matter in mixts.

A. L. BARKER.

**Action of ozone on artificial culture media and on various bacteria, yeasts, and molds.** R. HEISE. *Arb. kais. Gesundh.-Amt.* 50, 418(1917); *Chem. Ztg.* 42, 137(1918); *J. Soc. Chem. Ind.* 37, 634A.—An  $\text{O}_3$  concn. of 3 mg. per cu. m. of air was sufficient to kill in 3-4 hrs. more than 95% of the bacteria present as individuals on the surface of a culture medium. The  $\text{O}_3$  penetrates with difficulty into the medium and into masses of bacteria; consequently colonies were hardly affected. Low temp. favored the action of the  $\text{O}_3$ . Similar results were obtained with yeasts, which proved to be slightly more sensitive. Both the spores and the mycelia of molds growing on the surface of a medium were killed, but any mycelium below the surface was not killed. It is concluded that only a partial destruction of organisms present on the flesh of animals preserved in cold storage can be expected by the use of ozonized air, but sufficient to improve the keeping qualities of the meat. E. J. C.

**Observations on the rate of growth of *Bacillus coli*.** RAYMOND C. SALTER. Iowa State College, Ames, Ia. *J. Infect. Dis.* 24, 260-84(1919).—A study of the rate of growth of *B. coli* under various conditions led to the following conclusions: After a period of lag, the rate of growth at 37° in 1/4% Difco peptone is const. and at a max.

from 6 to 8 hrs. Subcultures, during a period of const. rate of growth, as previously shown by Barber and others, do not show lag. Crystal violet decreases the rate of growth of *B. communis* in dilns. as great as 1:1000000. The effect of the dye is greatest during the lag period. *B. communis* will not grow in  $\frac{1}{2}\%$  Difco peptone H<sub>2</sub>O containing a concn. of crystal violet greater than 1:200000. A slight inhibition of growth is caused by a diln. of 1:1000000. Brilliant green in dilns. of 1:600,000 and 1:10,000,000. inhibits the growth of *B. coli* in  $\frac{1}{2}\%$  Difco peptone. Inhibition disappears between dilns. of 1:6,000,000 and 1:10,000,000. A slight stimulation is noted at 1:10,000,000. Crystal violet and brilliant green have a greater inhibitive effect on rapidly growing cultures than on old cultures. The action of dyes varies in different ways. Bile salts stimulate the growth of *B. communis* when added to  $\frac{1}{2}\%$  peptone in dilns. as high as 0.3-0.5%. Higher concns. of bile salts inhibit growth; 1% shows marked inhibition. Increasing the concn. of peptone up to 5% stimulates the rate of growth. The lag period is shortened in the greater concns. of peptone. Addition of K<sub>2</sub>HPO<sub>4</sub> to peptone in amts. up to 1% accelerates the rate of growth. Addition of beef ext. to peptone increases the rate of growth of *B. communis*, 0.5% giving slightly more rapid growth than 0.3%. The age of the culture greatly influences the rate of growth of *B. communis* during the lag period. Both the generation times and the duration of the lag are greater in old cultures. A marked increase in lag appears after 3 days.

JOHN T. MYERS.

**Note on the nature of the reaction of *B. coli* on Endo medium.** REUBEN L. KAHN. U. S. Army. *J. Bact.* 3, 547-54(1918).—Both chem. and physical factors enter into the formation of typically metallic colonies of *B. coli* on Endo agar. During the growth of these organisms on Endo medium, they adsorb the various sol. substances contained in the medium and proceed to break down the lactose first. After ten to fifteen hrs. incubation the trace of lactose adsorbed is probably transformed into lactic and other org. acids, and the colony is colored red. On further incubation, the org. acids are probably reduced by the bacteria to aldehyde and alc., which volatilize from the surface, leaving the non-volatile fuchsin behind, thus producing a metallic sheen. The carbohydrate being disposed of, the organisms proceed to attack the nitrogenous materials. NH<sub>3</sub> and other substances are produced in which fuchsin goes back into soln., and ultimate decolorization takes place. Several references are given.

JOHN T. MYERS.

**Bacteriological notes.** I. Gas production by *Bact. pullorum*. II. *Bact. pullorum* infections in adult birds. III. Relation between sucrose fermentation and immunizing power by *B. avisepticus*. PHILIP HADLEY, DOROTHY W. CALDWELL AND BERTHA M. HEATH. R. I. State College. *J. Bact.* 4, 65-9(1919).—Gas production by *B. pullorum* may depend upon whether the cultures are grown in glucose ext. or in glucose infusion broth. *B. avisepticus* typically produces an acid fermentation in sucrose. Among several strains examd., however, one was negative for this sugar. In this instance the absence of sucrose fermentation was correlated with the ability to produce, in rabbits, resistance against powerful infections with virulent cultures, an ability possessed by no other strain. Whether this relation of biochem. features is coincidental or whether it is of some definite significance in immunity production remains a question.

JOHN T. MYERS.

**Studies in forage poisoning.** The relation of *Bacillus botulinus* to forage poisoning or cerebral spinal meningitis in horses. ROBERT GRAHAM AND A. L. BRUECKNER. *J. Bact.* 4, 1-21(1919).—An anaerobic, spore-bearing bacillus isolated from a corn silage, proved to be responsible for an outbreak of forage poisoning. It engendered

forage poisoning in a mule following the ingestion of 2 cc. of the sterile filtrate broth culture. 0.02 and 0.03 cc. broth culture *per os* generally proved fatal in guinea pigs in 22 to 84 hrs. A goat serum was produced which protected guinea pigs, mules and horses from lethal doses of the isolated organism. This antitoxin was also protective against *B. botulinus* toxin. Serum immune to *B. botulinus* contained agglutinins against the organism isolated from forage.

JOHN T. MYERS.

**Studies on the proteolytic enzymes of soil fungi and Actinomycetes.** SELMAN A. WAKSMAN. *J. Bact.* 3, 309-30(1918).—The proteolytic enzymes contained in the fungi studied appear to differ from known proteolytic enzymes of animal origin in the following particulars: Their range of optimum reaction is greater; a reaction neutral to litmus was found to be the optimum one for the majority. The temp. optimum is somewhat lower. Although acting best in a neutral or sometimes in a slightly acid medium they differ from animal trypsin in not being pptd. by safranin. The exoenzymes can pass through a Pasteur-Chamberland filter. The sugar content of the medium has no influence upon the production of proteolytic, exo- and endoenzymes of *Aspergillus niger*. Both exo- and endoenzymes are produced by microorganisms on protein-containing and protein-free media, but the activities of the enzymes from organisms grown on the media containing proteins are greater than those obtained from organisms grown on the protein-free media. The age of the culture at which the most active enzymes are obtained depends on the organism itself, its rapidity of growth, and the nature of the waste products produced in the medium. Fibrin and cryst. egg albumin are decompd. by both the exo- and endoenzymes of the organisms used. Small amts. of  $\text{NH}_3$  were found to be produced in the decompn. of peptone and casein by the proteolytic enzymes of the microorganisms studied. This fact indicates the probable presence of the desamidases among the enzymes produced.

JOHN T. MYERS.

**The differentiation of lactose-fermenting anaerobes from *B. coli*.** REUBEN L. KAHN. U. S. Army. *J. Bact.* 3, 561-4(1918).—Anaerobic lactose-fermenting organisms found in waters of the southeastern area of the U. S. appear to be unable to produce gas when grown anaerobically in Endo medium.

**Non-lactose fermenting bacteria from polluted wells and sub-soil.** I. J. KLIGLER. Rockefeller Institute. *J. Bact.* 4, 35-42(1919).—A study of the biol. and serological characters of the non-lactose-fermenting bacilli isolated from polluted well waters and contaminated sub-soils.

JOHN T. MYERS.

**A rapid method for the identification of bacteria fermenting carbohydrates.** J. BRONFENBRENNER AND M. J. SCHLESINGER. *Am. J. Pub. Health* 8, 922-3(1918).—After pointing out the significance of such a test in sanitary work, the authors outline the method as follows: One prepares medium containing 1.5% of agar, 0.5% NaCl, and 1% peptone. This mixt. is brought to boiling and the reaction not adjusted. At this point a suitable amt. of indicator is added and the medium distributed into small tubes containing 1 or 2 cc. of medium, autoclaved and stored on ice. When used the medium is melted and to it is added 0.1 or 0.2 cc. of a 20% lactose soln. While hot, this medium is deposited in drops on the inner surface of the bottom of a sterile Petri dish. This may be placed symmetrically by marking the outside of the dish. Each of these drops is inoculated from the suspected colonies or material, leaving two drops uninoculated on each plate, as controls. After this a fresh drop of the medium is placed over the inoculated drops, giving conditions of slightly lowered O tension favorable to carbohydrate metabolism of bacteria. In order to prevent the volatilized

acids formed in some drops from causing a color change in other drops, filter paper satd. with NaOH was placed in the top of the Petri dishes. When desired, sterile slides with a concave well may be used. The hollow of the slide is filled with lactose agar, prepd. as outlined above, and a sterile cover glass placed over it. This method greatly decreases the length of time required for the formation of gas.

FRED W. TANNER.

**A simplified fuchsin sulfite (Endo) agar.** MAX LEVINE. *Am. J. Pub. Health* 8, 864-5(1918).—The Endo medium ordinarily used gives variable results in confirmatory work with *B. coli*. In the past much importance has been attributed to the reaction but the work of Clark and Lubs would indicate that this is unreliable as formerly carried out. L. believes that it is preferable to use a medium whose reaction is automatically cared for in its prepn. He proposes the following medium: Distd. water 1000 g.,  $K_2HPO_4$  2 to 5 g., agar 15 to 30 g. Boil these ingredients until dissolved, replacing loss by evapn. with distd. water. The agar is then flaked in definite quantities and autoclaved. Just before use the following materials are added to each 100 cc. of agar: 1 g. or preferably 5 cc. of a 20% soln. lactose;  $\frac{1}{2}$  cc. of a 10 % alc. soln. of fuchsin;  $2\frac{1}{2}$  cc. freshly prepd. sodium sulfite which has been heated for a few min. in the Arnold or brought to a boil over a small flame. After this the medium is used in the usual way.

CARL L. ALSBERG.

**The state of the problem of carbon assimilation.** INGVAR JØRGENSEN AND WALTER STILES. *Scientia* 25, 196-207(1919); cf. *C. A.* 12, 2209. E. H.

**Cause of the poisonous action of coal-gas on plants.** C. WEHMER. *Z. angew. Chem.* 31, 1, 205-9(1918); *J. Soc. Chem. Ind.* 37, 745A; cf. *C. A.* 12, 591.—Expts. carried out by W. prove that the injurious action of coal-gas on the growth of plants and germination of seeds (*C. A.* 11, 3300; 12, 591) is due to HCN which is present in minute quantity in coal gas. E. J. C.

**Resin secretion in *Balsamorhiza sagittata*.** ERNEST CARROLL FAUST. Univ. Ill. *Bot. Gaz.* 64, 441-79(1917).—The results are reported of anatomical, ecological and physiol. studies of resin secretion in *B. sagittata*. F. concludes that the resin is a member of the resinic acid group, forming a salt with  $NH_4OH$  similar to that of abietic acid. The resinic acid is formed from a resin which in turn is derived from inulin by polymerization and reduction. The resin is a by-product of the metabolic activities of the plant, and it is probably toxic to the plant. It is stored in special tubes or canals in the endodermal region. T. G. PHILLIPS.

**Application of the biochemical method to the study of the leaves of *Hakea laurina*.** **Extraction of a glucoside (arbutin) and of quebrachite.** EM. BOURQUELOT AND H. HÉRISSEY. *Compt. rend.* 168, 414-7(1919).—*H. laurina* R. Br. is a tree belonging to the family Proteaceae. It is a native of Australia and is cultivated on the Mediterranean coast of France. The hot alc. ext. of 100 g. of the leaves was treated by B.'s method (*C. A.* 5, 967). The following conclusions were reached: (1) The leaves contain sucrose, as do those of all phanerogams. (2) They contain 2 glucosides, one having an index of reduction (cf. *C. A.* 5, 1971-2) greater than 570, the other less than 380. (3) They also contain a levorotatory substance which is not hydrolyzed by emulsin. Two substances were sepd. from the alc. ext. of the fresh leaves, and identified: (1) Quebrachite, or 1-methyinositol, m. 190°,  $[\alpha]_D$  -80.6°. Treatment with

HI gave 1-inositol,  $[\alpha]_D = -64.9^\circ$ . (2) Arbutin,  $[\alpha]_D = -60.5^\circ$ . Treated with emulsin, this gave an index of reduction of 670, calcd. for arbutin 700. Hydroquinone was found in the ether ext. of the hydrolysis mixt. Both of these substances have been found in the leaves of *Grevillea robusta* A. Cunn., a tree belonging to the same family. (Cf. C. A. 6, 1816; 7, 679.) T. G. PHILLIPS.

The temperature coefficient of photosynthesis. W. J. V. OSTERHAUT AND A. R. C. HAAS. *J. Gen. Physiology* 1, 295-8(1919).—The temp. coeff. of photosynthesis in the marine alga, *Ulva rigida*, between  $17^\circ$  and  $27^\circ$  is 1.81. This high figure is explained on the assumption that there occurs first a light reaction with a low coeff. followed by an ordinary reaction with a high coeff. CHAS. H. RICHARDSON.

### NORMAL.

Comparative metabolism of certain aromatic acids. II. Fate of *p*-hydroxybenzoic acid and *p*-hydroxyphenylacetic acid in the organism of the monkey. CARL P. SHERWIN. Fordham Univ. Med. School. *J. Biol. Chem.* 36, 309-18(1918); cf. C. A. 11, 2923.—"After feeding a monkey (*Macacus rhesus*) *p*-hydroxybenzoic acid 50-60% of it was isolated from the urine as the free acid. When a monkey received 1 g. of *p*-hydroxyphenylacetic acid 32% of it was found in the urine in an uncombined state. After feeding 4.5 g., 48.37% was regained from the urine in an uncombined state while 11.27% occurred (in combination with glycocholic acid) as *p*-hydroxyphenylacetic acid. *p*-Hydroxyphenylacetic acid, found in only a very small amt. by Salkowski and Salkowski (*Z. physiol. Chem.* 7, 171), was obtained in sufficient amts. for analysis and the prepn. of the Cu salt. The process of metabolism of the aromatic amino acids in the monkey is the same as that of the lower animals and different from that of man. The monkey excretes the *p*-hydroxybenzoic acid in the urine in an uncombined state while a partial combination with glycocholic acid takes place in the human organism. The *p*-hydroxyphenylacetic acid is partly excreted as *p*-hydroxyphenylacetic acid in the case of the monkey and lower animals but is excreted in an uncombined form in the urine of man." A. P. LOTHEP.

The influence of protein feeding on the concentration of amino acids and their nitrogenous metabolites in the tissues. H. H. MITCHELL. Univ. Ill. *J. Biol. Chem.* 36, 501-20(1918).—"The main purpose of the expts. was to det. whether or not an increase in the amino-acid concn. of the tissues actually occurred during protein digestion, and, second, to obtain information, if possible, as to the rate of amino-acid catabolism, by investigating the changes in concn. in the tissues of the nitrogenous metabolites of the amino-acids,  $\text{NH}_3$ , and urea. The investigation was undertaken with the conviction that the accumulation of a considerable amt. of data is requisite before satisfactory conclusions can be drawn; the problem is essentially a statistical one. The concn. of amino-acids,  $\text{NH}_3$ , and urea in the tissues of rats is comparable to that of the tissues of other mammals thus far investigated. In the young growing rat the concn. of amino-acid and of  $\text{NH}_3$  in the tissues is considerably higher than in the older animal. In adult rats, protein feeding has only an inconsiderable effect upon the amino-acid concn. of the tissues, while increasing distinctly the urea content. In young growing rats, on the contrary, protein feeding increases considerably the amino-acid and urea content of the tissues, and, less certainly, the  $\text{NH}_3$  content. The  $\text{NH}_3$  and urea content of the livers of rats, both fasting and fed, is in general higher than that of the muscles. The more rapid and general synthesis of proteins in the tissues of the young animal may require at all times a greater concn. of amino-acids and  $\text{NH}_3$ , upon which

to draw, which may be assured by a greater avidity of the tissues for these substances and a less intense catabolism of them than in the adult." The distinct increment in the amino-acid content of the tissues during protein digestion in the vigorously growing animal might be explained in any one of the following ways: (1) "The digestive and absorptive powers of the young organism are more vigorous than of the old, so that of a given protein ration, more is digested and absorbed in a given time, producing a higher amino-acidemia and, by this factor alone, a greater increase in the amino-acid concn. of the tissues. (2) The deaminizing function of the tissues, especially of the liver, in the young animal is less intense than in the old, permitting a greater influx of amino-acids through the portal circulation and a more delayed catabolism in the tissues. (3) The tissues of the young animal possess a greater absorptive power for amino-acids than those of the adult, so that the equil. in amino-acid concn. between tissues and blood is considerably more than 10:1." M. is inclined to the view that unchanged amino-acids rather than the  $\alpha$ -hydroxyl- and keto-acids arising in the metabolism of the amino-acids are responsible for the sp. dynamic action of protein. "It is quite conceivable that the qual. make-up of the amino-acid fraction of a tissue bears some relation to its rate of heat production, quite aside from any change in the size of this fraction. In the postabsorptive period it seems reasonable to suppose that the proteins of the tissue and the free amino-acids and peptides held in it have reached, or approximate to some sort of an equil., which is suddenly disturbed at times when there is an influx of amino-acids from the intestines, constituting a mixt. quite different from that normal to the tissue. This disturbance in tissue equil. may possibly initiate chem. changes leading to an increased tissue metabolism until a readjustment is made as the resultant of catabolic and anabolic transformations, and after several hours an equil. is again established. The fact, as Lusk has shown, that the different amino-acids occurring in proteins have very different sp. dynamic effects, perhaps lends some support to such theoretical considerations." There is no direct evidence that the  $\alpha$ -hydroxyl- and keto-acids exist in the tissues in more than traces and acids of the same type are produced in the metabolism of fatty acids and glucose, substances which have practically no sp. dynamic effect.

A. P. LOTHROP.

**Creatinuria. I. Exogenous origin of urinary creatine.** H. STEENBOCK AND E. G. GROSS. *Univ. Wis. J. Biol. Chem.* 36, 265-89(1918).—"In the pig creatine in the urine may or may not be produced by fasting. Animals giving every external appearance of being normal may or may not have creatine in the urine on such rations as it is customary to feed in good animal husbandry practice. Creatinuria obtained during fasting may be reduced by carbohydrate feeding or by administration of alk., but both treatments applied simultaneously need not necessarily prevent it. In addition acid administration resulting in a slight acidosis may or may not increase the creatine, and protein feeding, if sufficiently intensive, will always produce creatinuria, or if already present will increase it in degree. This effect obtains even during alkalosis and cannot be attributed to acids resulting from the metabolism of the protein mol. We realize fully that our conclusions are at variance with many that have been made on an apparently unimpeachable exptl. basis and we realize also that in the contentions here presented it may appear as though confusion in the study of creatine metabolism has been increased rather than diminished. On critical analysis this shows itself to be far from the case. We are convinced that in one form or another creatine is etiologically related to protein metabolism, whether of exogenous or endogenous origin, and that in addition, in a manner as yet unknown, it is related to the creatine stored in the muscles and other tissues as well. With this fundamental conception it becomes possible to correlate all reliable observations hitherto made on creatine excretion." In S. and G.'s opinion, creatine is an end-product in the catabolism of certain

precursors in the protein mol. just as urea is of others. It might be formed from the splitting of arginine in such a way as to leave the guanidine grouping intact in which case cleavage could occur at the linkage of the C chain with the imino group or the C chain might be deaminized and then oxidized to a 2-C residue, AcOH. In one case guanidine would be formed which would be acetylated as it is exceedingly toxic; in the other case guanidineacetic acid would result and methylation in either case results in the formation of creatine. The great variability in the amt. of creatine excreted under different conditions and the lack of a definite ratio between the total and creatine N may be explained on the basis that the metabolism of creatine precursors may proceed in different directions and that during maintenance and especially during growth, body tissue restitution, and milk production these precursors are utilized and not completely metabolized into creatine. The effect of protein feeding on the excretion of creatine is dependent on the supplementation of amino-acids in such a manner that after the demands of the body are satisfied no creatine precursors are left over to be metabolized into creatine. If creatine precursors are present in excess of the amts. demanded for protein synthesis, the excess is metabolized to obtain energy and part of the N is excreted as waste in the urine in the form of creatine. During excessive endogenous protein metabolism creatine precursors are liberated and creatine appears in the urine. On feeding protein yielding sufficient amts. of those amino acids already destroyed, the creatine precursors are utilized in protein synthesis and creatine disappears from the urine, but if the ingested protein is especially rich in creatine precursors, creatine does not disappear as excessive amts. will be formed from the exogenous protein metabolism. The non-appearance of creatine in the urine when excessive amts. of protein are fed to mature men where there can be no extensive utilization of creatine precursors in tissue construction and where conditions would soon be especially propitious for the formation of large amts. of creatine, must be explained on the basis "that either the metabolism of creatine precursors in these individuals proceeds primarily in another direction from that leading to creatine (with arginine this would mean breaking up the guanidine residue) or that the destructive ability of the individual for creatine is greater. The suggestion is made that the difference in the behavior of men and women in the facility with which creatinuria is produced on the ingestion of protein may be related to the well known variations in the activity of the thyroid and that the relations of the endocrine secretions to creatinuria might well be investigated under carefully controlled conditions.

A. P. LOTHROP.

## F. PHYSIOLOGY.

ANDREW HUNTER.

The significance of undissociated carbon dioxide in respiration. R. W. Scott. Western Reserve Med. School. *Am. J. Physiol.* 47, 43-59(1918).—The slow injection of  $\text{Na}_2\text{CO}_3$  (0.35 g. per kg.) changes the  $P_H$  of the arterial blood from a normal value of 7.4 to 7.8; total arterial  $\text{CO}_2$  is increased 100%, but the free  $\text{CO}_2$  remains at the normal level and the regular type of breathing maintains. It is concluded that: (1) There is no close parallelism between  $P_H$  of the arterial blood and respiration. (2) At slightly alk. levels of  $P_H$ , pulmonary ventilation is so regulated as to maintain the  $\text{CO}_2$  tension in the blood normal. (3) A condition of true alkalosis is accompanied by apnea only when the method used to lower  $P_H$  causes at the same time a sudden fall in the  $\text{CO}_2$  tension. (4) Undissociated  $\text{CO}_2$  acts as a sp. respiratory hormone; therefore, the physiol. effect of  $\text{CO}_2$  on respiration cannot be attributed solely to its acid properties when in soln.

J. F. LYMAN.

## G. PATHOLOGY.

H. GIDRON WELLS AND ANDREW HUNTER.

A note on crystallized gallstones. EDO CLAASSEN. *Am. J. Pharm.* 91, 164 (1919).—C. reports that a number of interesting bodies were passed by a woman, 45 years old. Most of them were small, grain-like; several, however, were of a larger size, up to that of a pea. Their color was yellowish, somewhat shiny; heated on Pt foil they melted at first, then evapd., leaving a little of a dark substance and, when ignited, burned with a yellow flame. They dissolved in hot alc., the soln. leaving four-sided rhombic plates when evapd. on a slide. The largest crystals were polyhedral with a diam. from 6 to 10 mm. and wt. up to 0.384 g. One of these, weighing 0.208 g., surpassed the others by its quite regular shape; it belonged to the regular (the tesseral) crystal system, being a combination of the predominant cube with the octahedron and the dodecahedron = 0000.O.00O., which was proven by measuring the angles by means of a hand goniometer. All the above properties are known to be the same as those of cholesterol.

W. G. GAESSLER.

Serum diagnosis of syphilis. The method of Vernes and syphilimetry. R. DOURIS AND R. BRICQ. Nancy. *Bull. sci. pharmacol.* 25, 321-324(1918).—Elaboration of a technic based on the expts. of Vernes for the serum diagnosis of syphilis. Cf. *C. A.* 12, 2009; 13, 38, 866.

E. S. HAMMETT.

The remote effects of absorption of urine from the colon: A case of traumatic unilateral uretero-intestinal anastomosis. ARTHUR B. CECIL AND ROLAND S. CUMMINS. Los Angeles, Cal. *J. Urol.* 2, 469-80(1919).—Marked toxic symptoms occurred which seemed to be dependent upon absorption of urine from the colon. Great improvement followed an unilateral nephrectomy.

JULIAN H. LEWIS.

The use of a provocative vaccine in determining the cure of gonorrheal urethritis. GERALD H. PEARSON. London, Ontario. *J. Urol.* 2, 455-68(1919). J. H. L.

Alkaptonuria and acetonuria. G. KATSCH. Marburg. *Deut. Arch. klin. Med.* 127, 210-41(1918).—A case of alkaptonuria in a boy 3½ yrs. old is described in which homogentisic acid is made to disappear completely from the urine by fasting. It is noticed that the amt. of acetone in the urine varied inversely with the amt. of homogentisic acid excreted. As aromatic amino acids and their derivs. can give rise to acetone. The author believes that the homogentisic acid is converted into acetone.

JULIAN H. LEWIS.

The connection of milksickness with the poisonous qualities of white snake-root (*Eupatorium urticaefolium*). WALTER G. SACKETT. Univ. Chicago. *J. Infect. Dis.* 24, 231-59(1919).—S. brings forth convincing evidence that "milksickness" or "trembles" of sheep is produced by the ingestion of white snake-root (*Eupatorium urticaefolium*). The poisonous principle can be extd. from the dried leaf powder of the plant with 95% alc. It is toxic for rabbits but not for guinea pigs. J. H. L.

Further observations on antigens used in the Wassermann reaction. E. H. RUXDIGER. Bismarck, N. D. *J. Infect. Dis.* 24, 204-17(1919); cf. *C. A.* 13, 614, 753.—Alc. ext. of dog heart gave 32%, and alc. ext. of guinea pig heart gave 34% positive results with the sera of 50 clinically non-syphilitic patients. Alc. exts. of human, beef and rabbit hearts gave positive results with these same sera. With the sera of known syphilitics the alc. ext. of beef heart and of rabbit heart frequently gave stronger positive results than did the alc. ext. of human heart. The results obtained with the alc. exts. of dog hearts and guinea pig heart corresponded to those obtained with alc. ext. of human heart, while the alc. ext. of sheep heart reacted less strongly. When antigen was added 15 min. after the complement the same results were obtained as when antigen was added 15 mins. before the complement. Antigen dilns. of 1:35,

1:45, 1:50 and 1:75 gave results that were identical with those given by a diln. of 1:25. Dilns. of 1:100, 1:200, and 1:300 gave irregular results, sometimes stronger, sometimes identical with, and other times weaker than those given by a diln. of 1:25. Dilns. higher than 1:300 usually gave weaker positive results than did the diln. of 1:25.

JULIAN H. LEWIS.

**The perfusion experiment in the study of cellular anaphylaxis.** W. P. LARSON AND E. T. BELL. *Univ. Minn. J. Infect. Dis.* 24, 185-90(1919).—A strong evidence of the cellular theory of anaphylaxis is the fact that an anaphylaxis reaction can be obtained in an animal after all its own blood is removed and replaced by that of another animal and that an isolated organ washed supposedly free of blood will give a reaction. The authors' expts. throw doubt on this evidence by showing that it is impossible to wash all the blood out of an organ by perfusion methods. The efferent fluid becomes free from blood and albumin in a short time, but these reappear if the perfusion is temporarily discontinued for a few mins. By perfusing organs with Locke's soln. containing India ink, the course taken by the fluid through the organ was mapped out. It was found that a surprisingly small part of the capillary system is really washed out by the perfusing fluid. This technic does not therefore remove circulating antibodies completely, as has been assumed, and this type of expt. does not establish the presence of cellular antibodies.

JULIAN H. LEWIS.

**Is diabetes mellitus an increase in the formation of sugar or a disturbance of sugar utilization?** S. BERNSTEIN AND W. FALTA. *Wien. Deut. Arch. klin. Med.* 127, 1-46(1918).—In mild forms of diabetes the gaseous metabolism under certain conditions is the same as in normal individuals. During a period when a full diet containing much carbohydrate is given, the respiratory quotient does not rise at first (filling of the glycogen depots); later it does rise, showing that sugar is burned. The increase is very much more marked when on a protein-poor diet. On intravenous injection of sugar the relations are just the opposite from what they are in the normal. There is little or no rise in the respiratory quotient and a glucosuria is produced. Injections of adrenaline lead to a glucosuria but no rise of the respiratory quotient. Injections of pituitary gland ext. cause a lowering of the heat production but no increase in the respiratory quotient. In diabetes of the severest form, it is not possible to increase the respiratory quotient by a carbohydrate-rich diet, by a protein-poor diet, or by intravenous injection of sugar, or by injecting adrenaline or pituitary gland ext. The extra sugar is completely excreted. From these facts it is believed that the metabolic disorder consists primarily of a lower ability of the body cells to take up sugar and to use it and does not consist of an over-production of sugar.

JULIAN H. LEWIS.

**Nature of the substances which play a part in the sigma (Wassermann) reaction.** LOUIS BORY. *Compt. rend. soc. biol.* 81, 128-30(1918).—B. proposes to substitute the word "sigma" for "Wassermann" in designating this reaction. Fixation of complement by syphilitic sera in the presence of an appropriate antigen is due simply to a quant. modification of the proteins of the serum, particularly globulin. This is indicated by the fact that a typical sigma reaction was obtained (without intervention of a sp. serum) by use of Desmoulières antigen, a 2:100 globulin (from horse serum) soln., physiol. NaCl soln. and guinea pig complement; the reaction was negative in the absence of antigen. Serine also plays an important, but less sp. role in the sigma reaction. The sigma reaction is a simple morbid reaction and is not a phenomenon of immunity. Josué, commenting on the above, suggests that the name of this reaction be changed to "Bordet" instead of "sigma."

H. S. PAINE.

**Appearance of precipitins in the serum of rabbits prepared by injections of egg white.** A.-CH. HOLLANDE AND J. GATÉ. *Compt. rend. soc. biol.* 81, 148-51(1918).

—Undild. egg white was subcutaneously injected 9 times (0.5, 1.0 and 1.5 cc. for the 1st 3 and 2 cc. each for the last 6 injections) at 6-day intervals in 2.5–3 kg. rabbits. The serum of the rabbits was examd. 6 days after each injection; pptg. power was detd. in the presence of egg white dild. 1:100, 1:1000, 0.5:1000 and 0.25:1000 with physiol. NaCl soln. Observations on 6 rabbits showed that precipitins first appeared after 30 days, reached a max. in 36 days, decreased after 42 days, and again increased toward the 54th day without attaining the values of the 36th day; individual variations in the different animals were noted. When rabbits received a single injection of 10–30 cc. undild. egg white no precipitins were detected in the serum, even in the presence of a 1:100 egg white soln. and after a period of approx. 2 mos. (examn. every 6 days). When undild. egg white was subcutaneously injected in amts. greater than 5 cc. the sera had little or no pptg. power, even though the injections were repeated every 6–8 days.

H. S. PAINE.

Some chemical examinations of urine and blood in the present gripe. G. PATEIN AND G. COLOMBET. *J. pharm. chim.* 18, 357–63(1918).—In the observation of 20 cases nearly always indoxyl and urobilin were present, as is often the case in infectious diseases. Albumin was not const., often absent, never abundant. The striking feature is the large amt. of urea in urine, confirming Marchadour and Dénier (*Acad. de méd.*, Sep. 10, 1918), who also mention the decrease of eliminated  $\text{Cl}^-$ . The formation of urea is the result of autocombustion, causing high temp. and falling off in wt. It is noted also in other pathol. conditions: Henry Reynès observed in cases of uremia in war wounds 40, 50, 60, 70 g. urea per 24 hrs. in concns. of 30, 35, 40 and 45 g. per l. As to occurrence of urea in blood serum, P. and C. find that while it is slightly above the av., it does not present the same abnormal state as in urine.

S. WALDBOTT.

Proteolytic nitrogen of the exudate of wounds in its relation to secondary sutures. W. MESTREZAT AND MARIANNE ROMME. *Compt. rend. soc. biol.* 81, 1147–50(1918).—The ratio of formol N of proteolysis (of wound exudates) to chlorides is proposed as a criterion for detg. when secondary sutures can safely be performed; since the chloride content of the blood is nearly identical with that of the exudates directly derived therefrom the amount of chlorides found in a compress is practically proportional to the vol. of exudate with which the compress is impregnated. The ratio is applied in the following form: formol index =  $100 \times \text{NH}_3/\text{NaCl}$ . This expression is proportional to the value of the N of proteolysis (autolytic and putrefactive) of the exudate of the wound under the conditions of the examn. and may also be regarded as a coeff. of putrescibility of the fluids of the wound. The detn. is performed as follows: The compresses (after being in place 48 hrs.) are digested  $\frac{1}{2}$  hr. in 100–300 cc. distd.  $\text{H}_2\text{O}$  at room temp. The liquid is filtered through glass wool and to 80 cc. of the filtrate are added 16 g. pure, crystd.  $\text{Na}_2\text{SO}_4$  and 1.5–2.5 cc. of 50%  $\text{AcOH}$  (according to the degree of purulence of the compresses). After heating 10 mins. on a  $\text{H}_2\text{O}$  bath to coagulate albumins the liquid is filtered through paper and the filtrate is used for detn. of chlorides (Charpentier-Volhard method) and formol N (Ronchèse method). A close relationship was observed between the values of the formol index and the results which followed secondary suture. In the case of old wounds of the fleshy parts of the body complete success attended secondary suture when the value of the formol index was less than 10. In the case of recent wounds it was preferable to perform only a secondary suture when the value of the formol index was less than 8.

H. S. PAINE.

The excretion of rest nitrogen and urea in the bile after nephrectomy. E. BECHER. Giesen. *Deut. Arch. klin. Med.* 127, 13–9(1918); cf. C. A. 13, 750.—After nephrectomy there is a vicarious excretion of N through several channels, one of which is the gall bladder. The increased N in the bile after nephrectomy in the dog is less than

that in the blood; the increased hypobromite N is about the same. The % of the amt. of retained N which is excreted in the bile is small. JULIAN H. LEWIS.

## H. PHARMACOLOGY.

ALFRED N. RICHARDS.

**Experimental research on the effect on the gastro-intestinal tract of the excretion of poisons, considering the age of the animals.** N. OKUBO. *Am. J. Dis. Children* 16, 376-87(1919).—The animals used were: rabbits, dogs and chickens, grown and very young, besides grown white rats and pigeons. The substances tested were injected subcutaneously and intravenously. They were: colloidal Bi, HgCl<sub>2</sub>, colloidal Ag, As<sub>2</sub>O<sub>3</sub>, K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, ricin, cantharidin, snake poison, emulsions of Shiga bacilli, paratyphoid B, typhoid and cholera bacilli. Three characteristics are pointed out with regard to the excretion of poisons in the intestinal tract of very young animals. (1) The excretion takes place diffusely and is consequently thinned. (2) The enteritis by excretion is anatomically of a diffuse character and less sp. to every poison offered. (3) The destructive process is relatively distinct in regard to the histol. findings, showing a diffuse epithelial alteration, while the reactive process is slighter in comparison with findings in grown animals. S. AMBERG.

**Cesium ions and heart activity.** [Biological antagonism between K, Rb, Cs and U, Th, Ra, Ra Em.] H. ZWAARDEMAKER. *Vers. Akad. Wetenschappen Amsterdam* 26, 776-81(1918).—An excized frog heart can be kept beating by replacing the KCl of Ringer soln. by either (A) CsCl or RbCl (40-80 mg. per l.) or (B) radioactive salt, namely UO<sub>2</sub>(NO<sub>3</sub>)<sub>2</sub> or UO<sub>2</sub>(OAc)<sub>2</sub> (1-6 mg. per l.) or Th(NO<sub>3</sub>)<sub>4</sub> (2-10 mg. per l.) or Ra salt (less than 3<sup>-4</sup> mg. per l.) or Ra emanation (less than 100 Mache units). The action of the salts A (to which also belongs KCl) is balanced by the salts B; if both are present in proper concn. the heart will be at rest; if one is present in excess the heart will beat again. Thus, e. g., a heart beating with CsCl (40 mg.) (= Cs-beating) comes suddenly to rest with Th(NO<sub>3</sub>)<sub>4</sub> (20 mg.) (= Cs-Th-equil.) and resumes beating (= Th-beating) again after 25 min. Compare also K-U-equil. in *C. A.* 11, 3058. The addition of fluorescein (100 mg. per l.) shifts the equil. (cf. *C. A.* 12, 2621), for a heart at rest by the presence of both (A and B) will resume beating. Fluorescein sensitizes the heart more for the influence of B than for A. Cs (like K and Rb) very probably emits β-rays, upon which its activity depends. Also in *Proc. Acad. Sci. Amsterdam* 20, 773-8(1918).

I. W. D. HACKH.

**The influence of hydrogen peroxide on the peristalsis of the isolated intestine.** H. J. HAMBURGER AND E. BROUWER. Univ. Groningen. *Vers. Akad. Wetenschappen Amsterdam* 26, 791-4(1918).—The rhythmic movements of intestines of rabbits suspended in Tyrode soln. are not changed by altering the flow of O through the soln. Addition of H<sub>2</sub>O<sub>2</sub>, however, increases the activity for a definite time period, after which the normal rhythm is again resumed. This is also observed in the presence of a narcotic (like CHCl<sub>3</sub>). A repeated dose of H<sub>2</sub>O<sub>2</sub> produces a weaker effect than the first one. The lowest concn. of H<sub>2</sub>O<sub>2</sub> causing a distinct reaction was 1:1,300,000. With a relatively high concn. (1:15,000) the contractions became smaller and smaller and finally ceased entirely, but by placing the intestines in a new Tyrode soln. the contractions slowly returned. It is probable that the substances necessary for the peristalsis are decomposed by H<sub>2</sub>O<sub>2</sub>. Also in *Proc. Acad. Sci. Amsterdam* 20, 861-4(1918).

I. W. D. HACKH.

**Physiological actions of essential oils.** S. FURUKAWA. *Tokyo Kwagaku Kwaishi* (*J. Tokyo Chem. Soc.*) 40, 42-59(1919).—Soly. of the oils in H<sub>2</sub>O, blood serum and milk serum and also the minimum concn. of the substances in aq. soln. at which a loach is killed were detd. The soly. of the substances in the 3 solvents is observed to

be the same. Values are: amyl alc. 0.4% (0.1% min. concn.), octyl alc. 0.03% (0.002%), decylol 0.0075% (0.0018%), citral 0.001% (0.0032%), citronellal 0.0005% (0.0028%), Me salicylate 0.013% (0.0067%), Et salicylate 0.010% (0.0039%), Pr salicylate 0.0006% (0.0037%), Bu salicylate 0.0003% (0.0041%), Am salicylate 0.00015% (—), phenol 0.5% (0.0045%), cymene 0.02% (0.0017%), carvacrol (0.0014%). From the data F. discussed the theory of narcosis. S. KOMATSU.

**The absorption of drugs and poisons from the ureter and pelvis of the kidney.** DAVID I. MACHT. Johns Hopkins Hosp., Baltimore. *J. Urol.* 2, 491-6(1919); cf. *C. A.* 12, 1215, 1488.—It seems that aconitine, cocaine, apomorphine and KCN are easily absorbed through the walls of the ureter and kidney pelvis. These findings are not only of theoretical scientific interest but are also of some practical importance and should be borne in mind by the practical urologist inasmuch as various drugs such as Ag compds., Th, etc., are introduced into these organs for diagnostic and therapeutic purposes. JULIAN H. LEWIS.

**The toxicity of cresylic acid.** ANNIE HOMER. *Proc. Physiol. Soc., J. Physiol.* 52, xxxiv(1918).—Cresylic acid dissolved in saline or serum adjusted to  $P_H$  6.6-7.0 may produce only a transitory effect in mice and guinea pigs when the same amt. in solns. adjusted to  $P_H$  8.3 may be fatal. When trikresol is used as an antiseptic in serum care should be used in selecting ampoules and bottles of a suitable quality of glass from which little or no alkali can be dissolved. J. F. LYMAN.

**Chemical stimulation of cerebral cortex.** S. S. MAXWELL. *Am. J. Physiol.* 47, 283-5(1918).— $NEt_4Cl$ , unlike other substances which stimulate medullated nerve, is also a stimulant of gray matter. J. F. LYMAN.

**Use of antiseptics in the treatment of infected wounds.** MAURICE CAZIN AND S. KRONGOLD-VINAVER. *Compt. rend. soc. biol.* 81, 1214-7(1918); cf. *C. A.* 12, 953.—C. and K. report results obtained with various antiseptics. The bactericidal action of  $AgNO_3$  in 1:200,000 soln. was only manifested in wounds with flora composed principally of the pyocyanic bacillus or staphylococci associated with diplococci and similar bacteria.  $AgNO_3$  in this concn. had a very favorable influence on proliferation of tissue.  $NaClO$  solns. prepd. according to Dakin or Daufresne so as to contain 5:1000 of  $NaClO$  were too caustic, as was distinctly shown by histological examn. of fragments of human skin after 2 hrs. contact with the soln. Javel soln. dild. in the proportion of 15 g. to 1 l. of  $H_2O$  contained only 0.427:1000 of  $NaClO$  and had no injurious action on human tissues (even after 24 hrs. contact). The dild. Javel soln. had greater bactericidal power than Dakin soln. and was particularly active in the case of wounds infected with anaerobes; sp. action on this group of bacteria was observed in a large no. of instances. In a no. of cases of particularly serious gangrenous wounds direct antiseptic action was effected by subcutaneous injections of Weinberg vaccine (against *B. perfringens*). In streptococcic infections the indirect bactericidal action of Leclainche and Vallée polyvalent serum yielded excellent results; its efficacy was slight in *B. perfringens* and septic vibrio infections. The above results emphasize the selective action of various antiseptics on bacteria. Disinfection of wounds should be systematically regulated according to the bacterial flora as detd. from day to day. H. S. PAINE.

**Use of solutions of sodium fluoride and cadmium sulfate for disinfection of war wounds.** PIERRE PHILARDEAU. *Compt. rend. soc. biol.* 81, 1228-30(1918).—P. studied the antiseptic action of a 4:1000  $NaF$  soln. and a 0.40:1000  $CdSO_4$  soln. on recent wounds which were treated with Dakin soln. prior and subsequent to these expts.; these concns. are greatly in excess of those which were found by Richet and Cardot to have a pronounced bactericidal action on lactic acid bacteria *in vitro*. Intermittent irrigation of the wound was practised for 10 days. The antiseptic action was unsatis-

factory; no intoxication or local irritation was observed.  $\text{NaF}$  produced an abundant fibrinous exudate which protected the bacteria from the action of this compd.;  $\text{CdSO}_4$  was less objectionable in this respect. The particular merit of Dakin's soln. consists in its action on exudates and the rapid liquefaction and elimination of protein material in process of necrosis; this is followed by disappearance of bacteria.

H. S. PAINE.

**Use and applications of chlorinated alum solution; general considerations relative to antiseptics.** W. MESTREZAT. *Compt. rend. soc. biol.* 81, 1211-4(1918); cf. C. A. 13, 232, 483.—M. makes the following classification of chem. compds. and products used in the treatment of wounds: (1) those (such as horse serum, physiol.  $\text{NaCl}$  soln., etc.) which permit free exercise of the local and general means of defense of the organism; (2) those which reinforce one or more of these natural means of defense; (3) those which have a peculiarly selective action (action on toxins, etc.). Chlorinated alum soln. belongs to the 2nd class and has a different action from the chlorinated solns. usually employed in that it provokes a considerable flow of lymph to the wound (comparable to that produced by hypertonic sera). It has an energetic detergent action and produces at the expense of the diseased tissues a coagulated and imputrescible magma which is eliminated on the compresses. It has a pronounced bactericidal action in addition to the above.

H. S. PAINE.

**Sapidity and stereoisomerism.** FRANÇOIS BARRAL AND ALBERT RANC. *l'Industrie chim.* 5, 279-81(1918).—The authors compare the stereoisomeric amino acids as regards their effect upon the sense of taste. Thus, *d*-phenylalanine and *d*-histidine are sweet, whereas the *l*-compds. are bitter. *d*-Tryptophan is tasteless, *l*-tryptophan slightly bitter in taste, and the racemic mixt. of the two is sweet. Several other similar instances among the amino acids are cited. No explanation for this phenomenon is given.

M. P.

**Action of antiseptics on the virulent bacteria of the rhinopharynx.** H. MÉRY AND LUCIEN GIRARD. *Compt. rend. soc. biol.* 81, 1251-2(1918).—M. and G. detd. the effect on mice (subcutaneous injection) of the rhinopharyngeal mucus of school children before and after treatment of the latter with 1:100 collargol (introduction through the nostrils so as to bathe the rhinopharynx); the mice died of pneumococcic septicemia in both cases. Similar results were obtained when gomenol was used instead of collargol. Treatment of the rhinopharynx with these antiseptics reduced the no. of bacteria but did not diminish the virulence of those which survived. The difference in the action of collargol and gomenol *in vitro* and *in vivo* is probably due to mechanical protection of the bacteria by mucus, folds of the mucosa, etc. These results explain the prevalence of pneumococcic infections in epidemics of influenza in spite of all the precautions which were observed.

H. S. PAINE.

**Present status of the question of the use of antiseptics.** PAUL CARNOT. *Compt. rend. soc. biol.* 81, 1166-92(1918).—C. discusses the question of the use of antiseptics in all its phases and especially the advance in knowledge of this subject which was made during the war (particularly with reference to the treatment of wounds). A large proportion of the antiseptics which were used with success during the war were only slightly bactericidal *per se* and apparently produced their effects indirectly through secondary chem. transformations on contact with the organism or parasitic microorganisms or through stimulation of the natural defensive reactions of the organism. The future course of the development of antiseptics should be directed along this line and also along the line of systematic study of a series of chem. compds. which should be modified by introduction of groups and chains with sp. action on bacteria and little or no injurious effect on the tissues.

## 12. FOODS.

W. D. BIGELOW AND F. F. FITZGERALD.

Detection of decomposition in foods. K. BRAUER. *Chem. Ztg.* 42, 421-2(1918); *J. Soc. Chem. Ind.* 37, 668A.—Incipient decompn. in sausages, preserved foods, etc., can be detected by inoculating dextrose-bouillon with a small portion of the sample, incubating at 38° for 24 to 48 hrs., and noting whether or not gas is produced during this period. If there is formation of gas, organisms capable of decomposing the food are present; further investigation by sub-cultures will, if desired, indicate the kind of organism. The dextrose medium employed is prepd. by dissolving 1 g. of meat ext. in 100 cc. of water, adding 1 g. of peptone and 0.5 g. of NaCl, sterilizing the soln., then adding 1 g. of dextrose, introducing portions of the soln. into a series of Einhorn fermentation tubes, and again sterilizing for a short time. E. J. C.

Analysis of commercial saccharin. II. The detection and estimation of impurities. H. DROOP RICHMOND AND CHARLES A. HILL. *J. Soc. Chem. Ind.* 38, 8-107 (1919).—The tests given in the U. S., British, and French pharmacopeias are in no instance specific for any impurity. The loss on drying in the water oven is taken as moisture, although if the sample is damp a minute portion of the saccharin (*s*) will be hydrolyzed. Moistening 1 g. *s* with 1 cc. H<sub>2</sub>O after each successive 2 hrs. heating showed steady increases in wt. Boiling with H<sub>2</sub>O showed 97.4% hydrolyzed in 96 hrs. and contact with H<sub>2</sub>O at room temp. showed 17.6% hydrolyzed in 166 days. In ashing it is advisable to heat gently to volatilize *s*, leaving the mineral matter. Strong heating at first will produce C, difficult to burn off. Acetone will dissolve *s*, leaving mineral impurities. Heat 1.5 g. *s* with 10 cc. of 70.5% H<sub>2</sub>SO<sub>4</sub> so that the liquid boils in 1 min. Boil for 1/2 min. exactly and pour into 15 cc. H<sub>2</sub>O (cold). "Seed" with a trace of *p*-sulfoaminobenzoic acid and place in ice H<sub>2</sub>O. If 1% of para acid is present crystals form in 1/2 hr.; if 3% is present they usually form on cooling before seeding and 10% begin to sep. while still hot. This test is believed more reliable for the *p*- acid than 4 others which are discussed. A table of solubilities of *s* and *o*- and *p*-sulfoaminobenzoic acids is given as the basis for the detection of the *o*- acid which is an unlikely impurity. A method is given for *o*-toluenesulfonamide, but good com. *s* contains only small traces of this. Methods for Pb and As are given. As *s* is hydrolyzed (with lowering of m. p.) on drying little importance is given to the m. p. test although official in U. S. and French pharmacopeias. The U. S. P. test for NH<sub>3</sub> is not very delicate. Nessler reagent is recommended. NH<sub>3</sub> is practically never found except in traces (below 0.01%). The boiling with 70.5% H<sub>2</sub>SO<sub>4</sub> for *p*-acid above shows easily carbonizable org. matter by brown coloration. Na<sub>2</sub>CO<sub>3</sub> 0.05 g. and *s* 0.1 g. in 1. of H<sub>2</sub>O can be compared with 5% sucrose soln. and on diln. the sweetness of *s* can be estd. to within 5%. No tests for salicylic and benzoic acids or glucose and milk sugar are given. Cf. C. A. 12, 2215. H. A. LEPPER.

**Use of hydrofluoric acid for preserving fruit juices.** A. BEYTHIEN AND P. PANNWITZ. *Z. Nahr. Genussm.* 36, 116-9(1918); *J. Soc. Chem. Ind.* 38, 25A.—HF and sol. fluorides have distinctly poisonous properties, and the use of the acid as a preservative for fruit juices is dangerous to health. The added HF cannot be removed completely by the addition of  $\text{CaCO}_3$  in quantity slightly larger than that required by theory, and if more than this quantity of  $\text{CaCO}_3$  is added, the quality of the fruit juice is affected.

E. J. C.

**Determination of carbon dioxide and carbonate in baking powder.** G. RUFF AND E. WOHLNICH. *Z. Nahr. Genussm.* 36, 101-10(1918); *J. Soc. Chem. Ind.* 38, 25A.—To ascertain the available  $\text{CO}_2$  and excess  $\text{NaHCO}_3$  in a baking powder, detns. are made of the total  $\text{CO}_2$  and the amt. remaining after a portion of the sample has been boiled with water for 30 min.; the difference between the 2 detns. gives the available  $\text{CO}_2$ . In the case of baking powders contg.  $\text{CaCO}_3$  in addition to  $\text{NaHCO}_3$ , the mixt. after boiling, must be filtered and the  $\text{CO}_2$  detd. both in the insol. portion and in the filtrate. All the detns. are made in a Keissler-Erdmann  $\text{CO}_2$  app.

E. J. C.

**Digestion of aleurone cells incorporated in bread as now made.** L. LAPICQUE AND A. LIACRE. *Compt. rend. soc. biol.* 81, 217-20(1918).—Flour mixed with  $\text{H}_2\text{O}$  and baked at  $100^\circ$  was fed to mice; the feces of the latter contained aleurone cells which were practically intact. When unmodified flour was fed to the mice the feces contained empty as well as intact aleurone cells, this being probably due to fracture of the envelope of the cells (thus permitting digestion of the contents) during mastication, whereas the baked flour paste was swallowed with little or no mastication. Examn. of French war flour after the latter was washed free of starch showed the aleurone cells to be all practically intact. The feces of man, mice and dogs after ingestion of bread made from this flour contained, however, very few intact aleurone cells; practically all of these cells had been ruptured during panification (as shown by microscopical examn. of the bread) and the contents had been digested. The aleurone cells remained intact in flour which had been simply mixed with  $\text{H}_2\text{O}$  and heated at the b. p. for  $\frac{1}{2}$  hr. The same was true when the mixt. was subjected to fermentation by yeast before heating. The rupture of the aleurone cells during panification is attributed to fracture of the envelope of the cells during remilling of the bran which is used in producing war flour and to the subsequent action of forces of traction and torsion in the glutinous mass during the processes of kneading and fermentation; the effect of these forces on the fractured envelopes of the aleurone cells which are imbedded in and adhere to the mass of dough is relatively powerful. There is no doubt, therefore, that as war flour is now prepd. most of the aleurone cells are digested and contribute to the food value of the bread. This utilized material constitutes about  $\frac{1}{3}$  of the portion of the flour which has heretofore been regarded as not possessing human food value. In an 85% flour containing 4-6% of aleurone envelopes this increase amounts to 1-2% of the total food value. The rupture of the aleurone cells is only effected during panification, however, in case the envelopes have been previously fractured during the milling process; such fracture is attributed primarily to remilling of the bran.

H. S. PAINE.

**The measurement of the acidity of bread.** EDWIN J. COHN, P. H. CATHCART AND L. J. HENDERSON. Harvard Univ. and Med. Dept., U. S. Army. *J. Biol. Chem.* 36, 581-6(1918).—"The degree of acidity is of importance in bread making in that it det. the physical state of the gluten, influences the growth and the activity of the yeast, and controls the growth of many other microorganisms, such as the rope-producing bacillus, *B. mesentericus*. The growth of the yeast and other microorganisms in turn influences the acidity of dough and of bread." A colorimetric method for measuring the relative acidity of bread is described in which the H-ion concn. is measured by means of the color produced when an ordinary indicator soln. of methyl red is allowed to fall

upon a slice of bread. The color produced varies from orange to red corresponding to initial values of  $P_H$  ranging from approx. 6.0 to 4.5. If the loaf is ropy, the color will be yellow due to the alkali produced in the metabolism of *B. mesentericus*. The H-ion concns. of suspensions of bread run closely parallel with the colors produced on the cut surface by the addition of methyl red. "The loaf is cut cleanly, and upon a point near the center of the loaf 4 drops of a 0.02% soln. of the indicator in 60% alc. are allowed to fall. After waiting 5 min. the color is observed. By comparison with a color chart or with a loaf of bread of known acidity, the H-ion concn. of a loaf of bread may be estd." The H-ion concns. of 54 loaves from the largest Boston bakeries varied from  $P_H = 5.01$  to 5.7.

A. P. LOTHROP.

German (prisoners of war) bread. W. PARTRIDGE. *Analyst* 44, 48(1919).—Analysis of one sample is given. Small yellowish particles embedded in the crust showed the structure of finely pulverized wood.

H. A. LEPPER.

Zeiss butyro-refractometer: The conversion of scale readings to refractive indices. J. F. LIVERSIDGE. *Analyst* 44, 48(1919).—The formula given by Roberts for the calcn. of  $n_D$  from the scale reading (C. A. 11, 410) is inconvenient for the converse. L. recommends as more convenient: scale reading =  $287.3 - \sqrt{97,966 - 703,235(n_D - 1.4)}$ .

H. A. LEPPER.

Some observations on the efficiency of the present standard agar for the estimation of bacteria in milk. H. J. SEARS AND LULU L. CASE. *J. Bact.* 3, 531-6(1918).

JOHN T. MYERS.

Methods of calculating added water in milk. LESLIE J. HARRIS. *Analyst* 44, 43-5(1919).—A table is given from which added water in milk can be calcd. when fat and solids-not-fat are known. The table is based on a formula previously derived (C. A. 13, 147). Directions are given for making an alignment chart or slide rule to simplify calcn.

H. A. LEPPER.

The fat-free dry residue of milk. N. SCHOORL. Utrecht. *Pharm. Weekblad* 55, 1645-64(1918).—The direct detn. of the dry residue of milk may give results which vary as much as 0.5%, on account of variations of manipulation by different investigators. Of the numerous formulas in use for calcg. the residue, all are about equally accurate; but each is limited to particular conditions of analysis. There should be an official standard method of analysis, and a corresponding formula for calcn. For this purpose, preference is given to the formula of Moeslinger:  $D_{ff} = (S + V)/4$ , or  $D = (S + 5V)/4$ , where  $D_{ff}$  is the fat free dry residue,  $D$  the dry residue,  $V$  the fat content and  $S = 1000$  (sp. gr. of milk - 1), which is the lactodensimeter unit. If the fat and sp. gr. detns. were uniformly carried out in conformity with this formula, the calcn. of the dry residue would be simple and sufficiently accurate. In judging the quality and nature of milk, this value is as important as that of the f. p. depression.

JULIAN F. SMITH.

Cooling milk and storing and shipping it at low temperatures. J. A. GAMBLE AND J. T. BOWEN. U. S. Dept. Agr., *Bull.* 744, 28 pp.(1919).—Expts. were conducted to det. (1) the relative efficiency of cooling tanks of different construction handled under varying conditions, (2) the most efficient method of cooling and storing milk on the farm, and (3) the transportation of milk at low temps. to market. Milk should be kept at a temp. of 50° or below in order to maintain its quality. The cork-insulated tank was found most efficient for the cooling of milk. The felt jacket or insulated cans proved very efficient in keeping milk during long shipments in hot weather and in preventing freezing during cold weather.

J. J. SKINNER.

Determination of water in margarine by heating in aluminium beakers. J. PRESCHER. *Z. Nahr. Genussm.* 36, 70-1(1918); *J. Soc. Chem. Ind.* 37, 746A.—The

usual method of detg. water in margarine by heating the sample in an Al beaker until the water has been evapd. presents some difficulty in the case of margarine as now sold in Germany. Excessive spurting takes place, probably owing to the presence of traces of soap (from the purification of the crude fats) and of potato starch; the soap appears to coat the starch granules and the steam escapes violently. Distn. with xylene or drying on sand in the water-oven is recommended in the case of such samples.

E. J. C.

**Fat extraction apparatus.** E. GRIFFITHS-JONES. *Analyst* 44, 45-7(1919); illus. —The thimble is attached to the end of a vertical condenser with a cork and is surrounded by a flask containing the solvent also attached to the condenser. A side tube parallel with the condenser leads from solvent flask to interior of condenser to level of  $H_2O$  intake. This app. was found more rapid than the Soxhlet.

H. A. LEPPER.

**Preservation of liquid eggs with boric acid.** A. W. J. MACFADDEN. *J. Soc. Chem. Ind.* 38, 50R(1919).—A review of the report of the work of the inspectors of foods 1917-18. Liquid eggs imported into England from China were found to contain 1.35-2.08% of  $H_3BO_3$  which is considered excessive. Packages containing an equiv. of 9-12 eggs designed for home use contained 40-113.4 grains per lb. Public health authorities have made it a condition on importation that the importer guarantee the eggs to be sold only to bakeries and confectioners where their use will only introduce negligible amts. of  $H_3BO_3$  and that they be not sold in small retail packages (under 7 lbs.) to consumers.

H. A. LEPPER.

**Formaldehyde in smoked meat.** M. ISHIO AND S. AOKI. *Yakugaku Zasshi (J. pharm. soc. Japan)* 443, 20-40(1919).—On testing 20 smoked meats obtained from Japanese markets, the authors observed that they contain  $1/10000$ - $1/10000$  HCHO. As regards the test for HCHO, they are of the same opinion as Kawahata and Namba (*C. A.* 12, 1217).

S. KOMATSU.

**Castor bean meal.** ANON. *J. Board Agr.* 24, 1444(1918); *Bull. Imp. Inst.* 16, 395(1918).—Trials were carried out to det. whether the residue of castor beans, after the removal of the oil, can be used satisfactorily for the feeding of pigs, and in particular to ascertain whether the toxic properties of the residue, which are due to ricin can be removed by submitting the material to a high temp. The heating process was carried out by the manufacturers but the temp. employed is not mentioned. The pigs refused to eat the meal when merely mixed with  $H_2O$  or with treacle. When the meal was given with house-wash of good quality which had been boiled and mixed with other meals, a considerable amt. was consumed with good results. In no case was any symptom of poisoning observed.

R. L. SIBLEY.

**Experiments with bolly refuse.** C. T. DOWELL AND W. G. FRIEDEMANN. Oklahoma Agr. Expt. Sta., *Bull.* 121, 2-8(1918).—Two steers were not only maintained but also gained in wt. with no impairment of health in a digestion expt. of 3 weeks on a lot of bolly refuse (material remaining from the ginning of bollies, partially opened or unopened bolls of cotton) from the Coyle Gin Co. The chem. compn. of this sample on the moisture-free basis was dry matter as weighed out 88.79, ash 5.77, protein 9.97, fiber 41.55, N-free ext. 40.30, and fat 2.41%; the mechanical analysis gave cotton 9.76, seed 15.5, and burrs 74.74%. This bolly refuse served as a good roughage on account of its large amt. of digestible carbohydrates resulting from the high % of unginned cotton. The bolly refuse from the Coyle Gin Co. was used by farmers as a cattle feed. The bolly refuse from the Thompson Gin Co. showed considerable variation in compn., due to closer ginning and was not used as a cattle feed but only as a fuel under the boilers of this gin. The mechanical compn. of a sample taken from this gin was cotton 3.87, seed 4.06, and burrs 92.07%. The ash from bolly refuse contains valuable

fertilizing constituents. One sample of bolly refuse ash (Thompson) contained  $P_2O_5$  7.45,  $K_2O$  32.01, and  $CaO$  12.27%. Another sample (Coyle) contained  $P_2O_5$  6.42,  $K_2O$  26.14, and  $CaO$  8.69%. One thousand lbs. of the bolly refuse from the Coyle Gin Co. contained  $P_2O_5$  3.30 lbs.,  $K_2O$  13.40 lbs., and  $CaO$  4.40 lbs. Analyses of the seed from bollies, and of the oil cake from bolly seed, showed that the seeds were of inferior quality, especially with reference to the oil content of the seed, and that the 2 samples of oil produced from bolly seed examd. were of low grade. W. G. F.

**Chopped soapweed as emergency feed for cattle on southwestern ranges.** C. L. FORSLING. U. S. Dept. Agr., *Bull.* 745, 20 pp. (1919).—Soapweed (*Yucca elata*) is a valuable feed so far as its chem. analysis is concerned. It occurs abundantly on the southwestern ranges, from western Texas to southern Arizona. It is higher in crude fiber and ash than fresh green alfalfa, immature corn silage, and fresh green timothy; the comparison in the amt. of ether ext., protein, and N-free ext. is favorable enough to indicate a good stock feed. Feeding expts. demonstrate that soapweed, with a supplemental ration of cottonseed meal or similar concentrates is practicable as a means of maintaining range cattle in time of drought. From 15 to 20 lbs. of chopped soapweed with 1 to 1.3 lbs. of cottonseed meal daily will maintain a cow. There was no accumulative ill effects on the digestive tract of cattle fed on soapweed over a long period, neither was there any harmful purgative effect except occasional scouring. J. J. SKINNER.

**Apparatus for desiccating milk.** C. H. CAMPBELL. U. S. 1,292,577, Jan. 28.

**Coffee extract.** W. A. HAMOR and C. W. TRIGG. U. S. 1,292,458, Jan. 28. In prepg. an aromatized coffee ext., volatilized caffeol is brought into contact with an absorbing medium such as petrolatum and the caffeol is then extd. from this absorbing medium by the use of alc.,  $CCl_4$  or other solvent, and the caffeol thus recovered is added to a concd. coffee ext. for use in making a beverage.

## 14. WATER, SEWAGE AND SANITATION.

EDWARD BARTOW AND W. F. MONFORT.

**A ready method for the extraction and estimation of dissolved gases in water.** F. W. RICHARDSON. *J. Soc. Chem. Ind.* 38, 32-3T.—“A stout glass bottle is completely filled with water. The lower tube of a bulb or thistle funnel head, of 50 cc. cap, and provided with 2 stoppers, as described in *C. A.* 4, 2590, is passed through a rubber stopper, the bulb is evacuated, and the stopper inserted into the bottle, thereby connecting the tube with the water. When the lower tap of the bulb is opened a little of the water rushes up, and it becomes possible to press the cock firmly into the bottle neck. Evolution of gas at once begins. If the bottle is placed in a vessel of water at about  $40^\circ$  and the gases are occasionally removed from the small bulb, the water will continue to boil until all gases have been removed.  $CO_2$  is tenaciously held by water, and when it is present alone repeated evacuations of the small bulb are necessary, but a number of experiments have proved that  $CO_2$  can be completely removed in the apparatus.” If the water contains much dissolved air in proportion to  $CO_2$  the latter is more easily removed. ERLE M. BILLINGS.

## 15. SOILS, FERTILIZERS AND AGRICULTURAL POISONS.

J. J. SKINNER.

**Saline soils and their improvement.** K. K. GEDROIC. Reprint, 1-16 pp.; *J. Soc. Chem. Ind.* 37, 598A.—G. describes the treatment necessary for the improvement of soils contg. excess of neutral salts, such as the so-called white alkali land, and those contg. soda, such as the black alkali land. E. J. C.

**Nitrification. II. Intensive nitrite formation in solution.** AUGUSTO BONAZZI. Ohio Agr. Exp. Station. *J. Bact.* 4, 43-59(1919).—The ordinary Omelianski soln. for the growth of the nitrite former studied will support a very abundant growth of this organism as measured by the production of the by-product of its growth,  $\text{HNO}_2$ , or its salts. The conditions under which this luxuriant growth was produced were shallow layers of the soln., slow rotary movement of the culture, and a temp. of  $25^\circ$  to  $30^\circ$ . The growths reported are far in excess of any previously reported for equal periods of time in soln. cultures. It would seem that better aeration may not be the only factor contributing to intensive nitrification, but that change of local environment is in some way associated with it. This assumption throws a new light on the study of conditions favoring growth in the solns. Whether this change of environment, if it proves to be actually operative, is associated with removal of by-products or better access of mineral nutrients, or possibly some other factor must be detd. by subsequent work. Numerous references are appended. JOHN T. MYERS.

**Nitrates, nitrification, and bacterial contents of five typical acid soils as affected by lime, fertilizer, crops and moisture.** H. A. NOYES AND S. D. CONNER. Ind. Agr. Expt. Sta. *J. Agr. Research* 16, 27-42(1919); cf. *C. A.* 12, 1808.—Two series of expts. were carried out with 5 types of acid soils, in one series the soils being treated with  $\text{CaCO}_3$ , acid phosphate, or complete fertilizer, and cropped with wheat or clover, while in the other the soils were uncropped and kept at  $1/4$ ,  $1/2$ , or full, moisture content. The results reported are acidity, crop yield (first series), nitrates when sampled and after, six weeks' incubation with  $(\text{NH}_4)_2\text{SO}_4$ , and numbers of aerobic, anaerobic and  $\text{CO}_2$ -surviving bacteria. All the soils were acid, the acidity being much reduced after the application of lime. The use of  $\text{CaCO}_3$  greatly increased nitrification in all soils as also did complete fertilizer to a lesser degree. Cropping with clover kept down the nitrate content. Soils kept  $1/2$  satd. with  $\text{H}_2\text{O}$  showed higher nitrifying power than those kept  $1/4$  satd., while those kept fully satd. were devoid of nitrates and showed no nitrifying power. The use of  $\text{CaCO}_3$  greatly increased the number of bacteria, especially the aerobes and small increases resulted from the use of complete fertilizer. Soils kept  $1/2$  satd. had the largest number of aerobes while the number of anaerobes was highest in the fully satd. soils. In general there was a close parallelism between the number of aerobes and the nitrifying power. R. N. HARGER.

**Manufacture of artificial fertilizers in the Dutch East Indies.** VAN REYERSBERG VERSLUYS. *Meded. v. d. Comm. tot Ontw. v. d. Fabrieksnijverheid in Ned. Indië* 1917,

No. 3; *Chem. Weekblad* 16, 78-9(1919).—A discussion of natural resources and possibilities of manuf. of fertilizers in the Dutch East Indies. Nothing is known as to phosphate deposits. Potash probably occurs, and some potash fertilizer is already being made from molasses. The fertilizer most used is  $(\text{NH}_4)_2\text{SO}_4$ , partly of domestic manuf., but mostly imported from England. The fixation of atm. N can probably be developed on a com. scale. Competition from Chile or Norway is not much feared.

JULIAN F. SMITH.

**Fertilizer from the effluent from potassium chloride works.** W. HÜTTNER. *Chem. Ztg.* 42, 434-5(1918); *J. Soc. Chem. Ind.* 37, 666A.—The effluent is introduced into a tank contg. quicklime, the latter being covered with the liquid; heat is developed and the whole is converted into a powdery mass which consists of  $\text{MgO}$ ,  $\text{Mg}$  and  $\text{Ca}$  oxychlorides, small quantities of  $\text{KCl}$ ,  $\text{NaCl}$ ,  $\text{CaSO}_4$ , etc. Its fertilizing value depends chiefly on the presence of the  $\text{Mg}$  oxide.

E. J. C.

**Flue dust.** J. A. VOELCKER. London. *Roy. Agr. Soc. England, Occasional Notes*, No. 3, 4-5(1918).—Attention is called to the variable  $\text{K}_2\text{O}$  content of flue dust, and it is recommended to purchasers that guarantees be demanded not merely as to the total amt. of  $\text{K}_2\text{O}$  in the material, but also as to the amt. that is sol. in water. An analysis of a typical flue dust showed 5.99% of total  $\text{K}_2\text{O}$ , and 2.65% sol. in water.

W. H. ROSS.

**Utilization of nitrogenous refuse (leather and horn waste, etc.).** E. DONATH AND G. ULRICH. *Chem. Ztg.* 20, 165-8(1917); *Z. angew. Chem.* 31, II, 218(1918); *J. Soc. Chem. Ind.* 37, 598A.—Refuse, rich in nitrogenous matter, is heated with waste  $\text{H}_2\text{SO}_4$ ; a portion of the N is thus converted into  $(\text{NH}_4)_2\text{SO}_4$  and the remainder is obtained in the form of a highly nitrogenous charcoal. Products which are practically dry, and rich in  $(\text{NH}_4)_2\text{SO}_4$ , are obtained by heating for several hrs. at over  $240^\circ$ . Chamber acid or waste  $\text{H}_2\text{SO}_4$  may be used. If larger proportions of acid are employed, pasty products are obtained from which fertilizer mixts. may be prepd. by combining them with ground limestone or phosphate. The yield of  $(\text{NH}_4)_2\text{SO}_4$  can be increased by carrying out the destruction in the presence of certain catalytic agents, preferably at  $250-70^\circ$ .

E. J. C.

**Potassium ammonium nitrate, a new top-dressing for sugar-beet.** M. HOFFMANN. *Deut. Zuckerind.* 43, 149-50(1918); *Z. angew. Chem.* 31, II, 313; *J. Soc. Chem. Ind.* 37, 744A.— $\text{K NH}_4$  nitrate prepd. from  $\text{NH}_4\text{NO}_3$  and  $\text{KCl}$  has been used in some places for small expts. It is easy to distribute over the land, and contains about 13% N, 25%  $\text{K}_2\text{O}$ , 3-4%  $\text{H}_2\text{O}$ , and 27-30% Cl. This material can be used with perfect safety as a top-dressing. It has the advantage over  $\text{NH}_4\text{NO}_3$ , that it can be spread more uniformly and is much less hygroscopic and explosive. According to Schneidewind,  $\text{K NH}_4$  nitrate has exactly the same action as an equiv. amt. of  $\text{NaNO}_3$ . It is proposed to put a  $\text{Na NH}_4$  nitrate on the market.  $\text{NH}_4\text{Cl}$  contg. 23-25% N has been put on the market this year, and has the same effect as the sulfate, but care must be taken in using it for plants sensitive to Cl.

E. J. C.

**By-product lime (Endlaugenkalk).** B. KOSMANN. *Tonind. Ztg.* 42, 579-80(1918); *J. Soc. Chem. Ind.* 37, 744-5A.—A very brief summary of the various processes patented for prepg. a lime fertilizer from the waste liquors obtained in the extn. of K from the Stassfurt salts. Essentially they consist in treating the liquor with an excess of  $\text{Ca}$  oxide.  $\text{Mg}(\text{OH})_2$  and  $\text{CaCl}_2$  are formed, and these, together with excess of lime, form the principal constituents of the product. An analysis of one sample is given, which contd. 9% of  $\text{Mg}(\text{OH})_2$ , 50% of  $\text{Ca}(\text{OH})_2$ , and 34.26% of calcium chloride ( $\text{CaCl}_2 \cdot 6\text{H}_2\text{O}$ ).

E. J. C.

**Analyses of county limestone deposits.** J. W. AMES. *Mo. Bull. Ohio Agr. Exp. Sta.* 3, 222-3(1918).—Analyses of 254 samples from various parts of the state are given. Results are expressed in terms of percentage of  $\text{CaCO}_3$  equiv. to the neutralizing power of the Ca and Mg content. A. suggests that many of these deposits not developed commercially might serve as local sources of ground limestone for agricultural uses.

T. G. PHILLIPS.

**New experiments in potassium fertilization.** H. G. SÖDERBAUM. *Kgl. Landtbruks-Akad. Handl. Tid.* 57, 501(1918).—*Experiments with marine salts:* These salts are made to simulate such as may be obtained through the evapn. of sea water. They are characterized by a low content of KCl and a high content of NaCl and  $\text{CaCl}_2$ . The results showed that the presence of Cl up to a certain amt. was of benefit to the formation of seed, oats being the cereal tried. Beyond a certain amt. the Cl was very harmful. The most significant result was that a large amt. of Cl can be tolerated in the presence of a sufficient amt. of lime, showing that these marine salts can be used on soils rich in lime or on soils to which large amts. of lime have been added. *Experiments with potash-lime:* This is manufd. by mixing one part of feldspar of high potassium content, one part limestone and one part gypsum, all ground fine, briqueted and burned at  $1180^\circ$ . Application of this material gave larger crop increases than the check pots in which a mixt. of 80% KCl, 10% NaCl, and 10%  $\text{CaCl}_2$  was used for comparison. That this soil was in need of lime was shown by the good results obtained from the application of  $\text{CaCO}_3$  from marble. The good results obtained from the use of potash-lime can in a measure be ascribed to the benefit from the extra addition of lime.

C. O. SWANSON.

**The effect of manganese on the growth of wheat; a source of manganese for agricultural purposes.** J. S. MCHARGUE. *J. Ind. Eng. Chem.* 11, 332-5(1919).—Wheat plants grown in both pot and water cultures with and without Mn were found to exhibit in the absence of Mn a lack of chlorophyll development and a tendency to droop, which was not observed at any time in the case of plants receiving Mn. The use of the Mn in suitable diln. was observed to stimulate the growth of the wheat and to increase the size and N content of the grain, and thus evidently performs an important function in the normal growth and development of the plant. Basic slag contains about 100 lbs. of Mn to the ton, and it is thought possible that some of the benefit to crops resulting from the use of this fertilizer on certain soils may be due to this element. A convenient support is suggested for growing plants in water cultures.

W. H. ROSS.

**Continuation of field trials with newer nitrogenous fertilizers.** SIGURO RHODIN. *Kgl. Landtbruks-Akad. Handl. Tid.* 57, 443(1918); cf. *C. A.* 7, 1573; 8, 195.—While  $\text{CaCN}_2$  is the cheapest of the newer nitrogenous fertilizers, the fine powdered form is objectionable because of the difficulties in handling. Before it can be utilized by plants it must undergo chemical change, and to bring this about rapidly, catalyzers are needed. The soil furnishes these and also carbonaceous matter. To test the advantage of adding these catalyzers to the  $\text{CaCN}_2$  before it was applied to the soil was the object of these expts. The catalyzers added were calcd. also to improve the physical condition of the  $\text{CaCN}_2$ . A number of substances were used, mostly by-products from iron and stone works, carrying Fe, Mn or Al. In addition to these NaCl and powdered charcoal were used. The field trials were so contradictory with respect to most substances that no definite conclusions could be drawn except with powdered charcoal. The pronounced results obtained from this substance are thought to be due to the great adsorptive power of charcoal. Ordinary Norwegian saltpeter, basic Norwegian saltpeter,  $\text{CaCN}_2$ ,  $(\text{NH}_4)_2\text{SO}_4$  from German coke ovens,  $(\text{NH}_4)_2\text{SO}_4$  from Swedish gas works,  $\text{NH}_4\text{NO}_3$  from the Norwegian Hydro-electric Nitrogen Stock Co., were used in field trials with

ordinary Chili saltpeter as a standard for comparison. The largest increase was obtained with  $\text{NH}_4\text{NO}_3$ , followed by the different kinds of saltpeter, all of which produced essentially equal results. The  $(\text{NH}_4)_2\text{SO}_4$  was third in value while the smallest increases in the crop were obtained from the use of  $\text{CaCN}_2$ . C. O. SWANSON.

**Farmer's experiment plots.** Southern district. H. C. STENING. *Agr. Gas. N. S. Wales* 29, Pt. 10, 717-23(1918).—Summer fodder expts. (1917-18) were conducted with 5 varieties of maize, 3 saccharine sorghums, 4 non-saccharine sorghums, and a variety each of black cowpeas, Japanese millet and Sudan grass. The original article should be consulted for details of the results of the variety tests. Fertilizer tests with Funk's Yellow Dent were also conducted. R. B. DEEMER.

**Effect of carbon disulfide and toluene upon nitrogen-fixing and nitrifying organisms.** P. L. GAINNEY. *Kans. Agr. Expt. Sta. J. Agr. Research* 15, 601-15(1918); cf. *C. A. S.* 8, 1634.—Using the methods employed in previous work, soils rich in nitrifying organisms were treated with varying amts. of toluene or  $\text{CS}_2$ , the moisture content of the soils being varied, and the soils were incubated for 6 months, and at intervals analyses were made for *Azotobacter*, nitrates and  $\text{NH}_3$ . Both toluene and  $\text{CS}_2$  when applied in sufficient quantities destroyed *Azotobacter* and checked nitrification, the quantities needed to do this increasing with rise in moisture content up to about 10% of  $\text{H}_2\text{O}$ , greater moisture content having little effect. The *Azotobacter*, if affected at all, was usually killed, and at this point the rate of nitrification was  $\frac{1}{4}$  to  $\frac{1}{2}$  as great as normal, showing that other organisms than *Azotobacter* cause nitrification, and to destroy these latter organisms much more of each chemical was required, and even 10 cc. of toluene per 50 g. of soil failed to destroy all nitrification. An accumulation of  $\text{NH}_3$  occurred only where nitrification was checked. R. N. HARGER.

**Lime-sulfurs.** VERMOREL AND DANTONY. *Compt. rend. acad. agr.* 5, 161-4 (1919).— $\text{CaS}_2\text{O}_3$ ,  $\text{CaS}_4$ ,  $\text{CaS}_5$  and oxysulfides of Ca are contained in the soln., while S, CaO,  $\text{CaSO}_3$ ,  $\text{CaSO}_4$  and oxysulfide of Ca occur in the sediment. At ordinary temp. oxysulfides of Ca and  $\text{CaS}_2\text{O}_3$  and a little  $\text{CaS}_4$  are formed after contact of several months. The quantity of sol. salts formed increases with increase of temp. up to  $100^\circ$ .  $\text{CaS}_2\text{O}_3$  is chiefly formed at low temps. and sulfides predominate at elevated temps. though the absolute quantity of thiosulfate increases. The content of dissolved S increases with time of boiling up to 45 min. and then decreases. Tetrasulfide is first formed and then pentasulfide progressively appears. The max. S in soln. is obtained with a proportion of 3.2 of S to 1 of Ca. Below 2.9 of S to 1 of Ca pentasulfides are obtained, above this a mixt. of tetra- and pentasulfides. The quantities of S and CaO that dissolve increase with increase of  $\text{H}_2\text{O}$  up to 3.1 of  $\text{H}_2\text{O}$  to 1 of the sulfur and lime mixt. The slower the cooling the less the proportion of  $\text{CaS}_2\text{O}_3$ . The greater the surface exposed to air the more the  $\text{CaS}_2\text{O}_3$  formed. MgO caused a loss of S by disengagement of  $\text{H}_2\text{S}$ . The presence of an excess of CaO in the sediment tends to the formation of oxysulfides of Ca. The d. of the soln. does not regularly accord with the content of S and consequently it is no criterion on which to base an estimate of the S in soln. ALBERT R. MERZ.

---

**Potash salts in Hungary (KONEK-NORWALL) 18.** Bolly refuse (DOWELL, FRIEDEMANN) 12.

---

**Fertilizer.** A. FOSS. U. S. 1,292,293, Jan. 21. A fertilizer is prepd. by adding sufficient  $\text{HNO}_3$  to raw phosphates associated with  $\text{CaCO}_3$  to render them sol., stirring the mass while it is in a semi-liquid state and simultaneously passing a current of air through it. Cf. *C. A.* 12, 1811.

## 16. FERMENTED AND DISTILLED LIQUORS.

ROBERT WAHL.

Food value of the ciders sold in open market. A. GUILLAUME AND H. CHLO. *Bull. sci. pharmacol.* 25, 334-42(1918).—Samples of ciders purchased by French troops during 1917 and 1918 gave the following minimum and maximum figures on analysis: Total alc., 0.0-0.94°; dry matter, 1.40-13.70%; reducing substances, 0.65-7.85%; total acidity, 1.52-3.53%; ash, 0.30-1.50%. The ciders made by the soldiers had a greater food value as evidenced by the following: Total alc., 1.20-4.02°; dry matter, 6.10-46.60%; reducing substances, 0.90-31.66%; total acidity, 1.91-2.80%; ash, 0.30-3.70%. A brief description of the process of manuf. is given.

F. S. HAMMETT.

Utilization of residues from Brunswick beer (wort). O. REINKE. *Chem. Ztg.* 42, 367(1918); *J. Soc. Chem. Ind.* 37, 557A.—In the manuf. of strong Brunswick beer, the wort is evapd. until it contains 60% of ext., and then filtered. The residue thus sepd. still contains about 54% of sol. matter which may be extd. and used over again, while the insol. portion, when dried and roasted, forms a coffee substitute. E. J. C.

Decarbonation of water used for diluting war beers. H. KRUMHAAR. *Woch. Brau.* 35, 121(1918); *J. Soc. Chem. Ind.* 37, 779A.—K. discusses the possible effects of carbonates present in waters used for dilg. beers. The formation of ppts. by interaction with the salts in the beer is not to be feared, since the concn. of the reacting substances is very low and the temp. also is low. Carbonates will, however, reduce the acidity of the beer by partially neutralizing free lactic acid. In some cases, e. g., lager beer, this is not of great importance; but where the character of a war beer depends on the presence of free acid, dilg. water rich in carbonates should be decarbonated.

E. H.

Influence of stimulants and of storage under water and beer, on the maltase-activity of yeast. F. SCHÖNFELD AND M. KORN. *Woch. Brau.* 35, 129-32(1918); *J. Soc. Chem. Ind.* 37, 779A.—Treatment of bottom-fermentation beer yeast with 4% solns. of  $K_2PO_4$  for several hrs., was found to stimulate the activity not only of the ymase but also of the maltase (see *C. A.* 12, 972, 973). The maltase activity was also increased by treatment with 0.6% solns. of lactic, phosphoric and tartaric acids, especially by the first named. Yeast stored under water suffered a very slow reduction of maltase-activity, amtg. to about 25% in 8 days. Storage under beer produced a more rapid change in the same direction. In general, conditions which affect the ymase of living yeast appear to exert a similar effect on the maltase.

E. H.

Iron-sickness in thin beers. W. WINDISCH. *Woch. Brau.* 35, 69-70, 95-6, 109-10(1918); *J. Soc. Chem. Ind.* 37, 779A.—In Germany war beers of very low gravity have proved subject to a malady resembling the iron-sickness of wines, which is due to the formation of ferric tannate. The beers affected become greenish and eventually blackish in color, and acquire an inky flavor. It is suggested that the Fe is probably dissolved by the wort after fermentation owing to contact with naked metal, or is introduced into the beer in the water used in some cases for diln. Decarbonation by boiling appears to render some waters more "aggressive" towards Fe, so that contact of such waters with the metal, during cooling or afterwards, becomes a source of danger. Cf. following abstract.

E. H.

Maladies of thin beers. W. WINDISCH. *Woch. Brau.* 35, 153-6(1918); *J. Soc. Chem. Ind.* 37, 779A.—The war beers of low gravity produced in Germany have been remarkably free from maladies due to microorganisms. The chief troubles have arisen from tannin-protein turbidity and Fe-sickness (cf. preceding abstr.), in both of which tannin plays an essential part. Some amelioration might be effected by reducing the

tannin content of the beer, *e. g.*, by using a smaller proportion of hops or extg. them with cold water before use, or by promoting the soln. of proteins during mashing with a view to the subsequent pptn. of tannins. The fact that the maladies are almost confined to beers of 3% gravity or under, probably indicates that these beers are deficient in some protective constituent, which W. conceives to be free acid. He therefore advocates higher acidities in thin beers, and in this connection recommends treatment with lime as the most economical and effective means of decarbonating brewing waters.

## 17. PHARMACEUTICAL CHEMISTRY.

---

W. O. EMERY.

A review of the advances in pharmacy. J. K. THUM. *Am. J. Pharm.* 91, 157-63 (1919); cf. C. A. 12, 2406.

W. G. GAESSLER.

Examination of a sample of gum asafetida. EDO CLAASSEN. *Am. J. Pharm.* 91, 164 (1919).—C. found adulterations representing nearly half the quantity of the gum as follows: gum 54.45%, calcite 35.51%, and granite 10.04%. W. G. GAESSLER.

Sulfuric acid test for strophanthus seeds. P. BOHRISCH. *Pharm. Zig.* 63, 318-9 (1918); *J. Soc. Chem. Ind.* 27, 559A.—The H<sub>2</sub>SO<sub>4</sub> test for strophanthin, by which a green coloration is obtained immediately with the official (Kombé) variety of seed, has not been very accurately specified. Especially when the word "cross-section" is interpreted to mean the surface of a seed which has been cut in half, the indications of the test are variable and indefinite. B. had investigated the various modifications of the test which have been proposed, and recommends the following procedure: Thin cross-sections of the seeds are placed on an object glass and treated with a little Et<sub>2</sub>O to remove the fat; they are then covered with 1 drop of H<sub>2</sub>SO<sub>4</sub> which has been dild. with 1/4 of its wt. with H<sub>2</sub>O. The endosperm and at least the outer portions of the embryo leaves show a deep green coloration, which is best observed under a low-power microscope or a strong magnifying glass.

W. O. E.

Keeping qualities of trypaflavin solutions. A. ABELMANN. *Pharm. Zig.* 63, 270 (1918); *J. Soc. Chem. Ind.* 37, 559A.—The yellow dyestuff trypaflavin (diaminomethylacridinium chloride) is employed therapeutically in the form of a 0.1% soln. as a bactericide which is comparatively non-toxic to animal tissues and preserves its activity in presence of serum. The 1% soln. is extremely sensitive to strong sunlight; it turns brown after exposure for 1 day, the brown color slowly increasing on further exposure to light. A soln. exposed to light and left open to the air for a month became dark brown and developed a growth of *Actinomyces*, in spite of undecomposed trypaflavin still present. With the addition of Na<sub>2</sub>CO<sub>3</sub>, sulfite, or chloride, decomposition takes place with the formation of a brown ppt., but the liquid remains bright yellow on exposure to light. Trypaflavin solns. keep perfectly well in the dark, and decompose only slowly in diffused daylight; 1% solns. are considerably more stable than 0.1% solns. Addition of AcOH or citric acid, or of H<sub>2</sub>O<sub>2</sub>, produces the brown color even in the dark, and must therefore be avoided. Adequate protection from light by the use of dark colored bottles and preservation in the form of more concd. solns. are recommended.

W. O. E.

Scammony and its substitutes. W. L. SCOVILLE. *J. Ind. Eng. Chem.* 11, 335-6 (1919).—A recently examd. sample of *Tesina drastica* revealed general characteristics resembling both true and Mexican scammony resins. It is slightly more acid and

strongly levorotatory ( $-32.4$ ); acid no., 28; sapon no., 136; color with  $\text{FeCl}_3$ , dark green. Its color alone would distinguish it, and treatment with decolorizing charcoal does not take out the color appreciably. Freshly pptd. it has an agreeable tea-like odor which disappears on drying. Probably a small amt. of volatile oil is present in the drug. The powdered resin resembles scammony resin in odor. W. O. E.

**Adulteration of neosalvarsan.** L. P. J. PALET. *Ann. fals.* 11, 299-300(1918).—A sample purporting to be "Novarsenobenzol Billon" was found to consist of some phenolic substance, sulfates and other salts of Na, together with coloring matter. Injection in a rabbit failed to produce any reaction worthy of mention. A test for As was negative. In this connection are mentioned numerous cases of substitution or sophistication of salvarsan and neosalvarsan, in Argentine and other countries of S. America, with NaCl and corn starch colored with picric acid. W. O. E.

**Detection of hydrochloric acid in chloroform.** *Ber. pharm. Ges.* 28, 385-8(1918); *J. Soc. Chem. Ind.* 38, 55A.—Ten cc. of  $\text{CHCl}_3$  are treated with a minute particle (about 0.01 mg.) of *p*-dimethylaminoazobenzene; if free HCl is present a violet-red coloration results; otherwise the soln. remains yellow. An excess of the indicator must be avoided, since the yellow color may mask a feeble coloration given by a mere trace of the acid. In doubtful cases, it is advisable to treat a further quantity of the  $\text{CHCl}_3$  with a few drops of the first portion containing the indicator. This method is more sensitive and reliable than the usual way of testing  $\text{CHCl}_3$  by shaking with  $\text{H}_2\text{O}$  and then testing with litmus, as there is risk of gradual decompn. of the  $\text{CHCl}_3$  in the presence of  $\text{H}_2\text{O}$ .  $\text{CO}_2$  and anhydrous  $\text{CO}_2\text{H}_2$  and  $\text{AcOH}$  do not give a red coloration with *p*-dimethylaminoazobenzene in  $\text{CHCl}_3$  soln. W. O. E.

**Digitalis substances.** XXXVIII. H. KILIANI. *Ber.* 51, 1613-39(1918); *J. Soc. Chem. Ind.* 38, 54A.—A record of some neutral and acid substances obtained by the oxidation or reduction of digitogenic acid, gitogenic acid, digitoxigenin, and digitaligenin. The sugar sirup previously obtained (cf. *C. A.* 10, 2720) could not be made to crystallize because the sugars in the sirup, which had been prepd. in an alc. medium, were present chiefly in the form of Et glucosides. After a 2nd hydrolysis with HCl, a partial crystn. was effected and *d*-galactose obtained by inoculation; dextrose, identified as *d*-gluconic acid, and apparently a 3rd sugar, a ketose, were also present. W. O. E.

**Detection of quinine.** H. SALOMON. *Ber. pharm. Ges.* 28, 273-5(1918); *J. Soc. Chem. Ind.* 38, 54A.—The fluorescence produced when a quinine soln. is treated with dil.  $\text{H}_2\text{SO}_4$  is a very sensitive test and will detect 1 pt. of the alkaloid in 100,000 pts. of soln. A less sensitive test (1 in 10,000) consists in treating the quinine with Cl and then with  $\text{NH}_3$ , a green coloration being produced (thalleioquin reaction). It is recommended that Br be used in place of Cl in this test; the Br water must be added cautiously until the soln. is just colored yellow and a drop of  $\text{NH}_3$  then introduced. Another reagent for quinine recommended by Giemsa and Halberkann (*Deut. med. Wochschr.* 1917, No. 48) consists of KI 10,  $\text{HgCl}_2$  2.7,  $\text{H}_2\text{O}$  200, and  $\text{AcOH}$  2.5 g. This gives a turbidity with a soln. containing 1 pt. of quinine in 200,000 pts. To detect quinine in urine, the alkaloid should first be extd. with  $\text{Et}_2\text{O}$ . W. O. E.

**Constitution of substances from gualiacum resin.** G. SCHROETER, L. LICHTENSTADT AND D. IRINEU. *Ber.* 51, 1587-1613(1918); *J. Soc. Chem. Ind.* 38, 55A.—Among the products obtained by the dry distn. of guaiacum resin are 2 substances of unknown constitution, pyroguaiacin and guaiene. The latter is now shown to be 2,3-dimethylnaphthalene by its synthesis. Pyroguaiacin is almost certainly 6-hydroxy-7-methoxy-2,3-dimethylnaphthalene. Guaiaretic acid, extd. from guaiacum resin by  $\text{Et}_2\text{O}$ , has the formula  $\text{C}_{20}\text{H}_{24}\text{O}_4$ , not  $\text{C}_{20}\text{H}_{26}\text{O}_4$  as stated by Herzig and Schiff (*Monats.* 18, 714-21 (1897); 19, 95-105(1898)). It is optically active,  $[\alpha]_D = -94^\circ$  in alc., and unsatd.

Herzig and Schiff's norguaiaretic acid is shown to be norhydroguaiaretic acid. Hydroguaiaretic acid methyl ether is most probably  $\alpha,\delta$ -diveratryl- $\beta$ -dimethylbutane, and guaiaretic acid methyl ether has the formula  $C_6H_5(OMe)_2.CH:CHMe.CHMeCH_2C_6H_5(OMe)_2$ . The synthesis of 1,2-dimethylnaphthalene,  $b.p.$  139-40°, is described.

W. O. E.

The history of compressed drugs. The dry salves of the Roman oculists. M. BOUVET. *Bull. sci. pharmacol.* 26, 28-32(1919).—A brief historical résumé of the development of the prepn. of drugs in tablet form.

F. S. HAMMETT.

A study of new methods of extraction and analysis of alkaloids. L. R. DE ROSEMONT. *Bull. sci. pharmacol.* 26, 23-8(1919).—On the basis that the use of dil. mineral acids in the extn. of alkaloids causes variability in the product, R. advocates the use of dil. org. acids in their place and gives detailed directions for methods of procedure when 2.5% acetic, oxalic, tartaric, citric, and  $\beta$ -naphthalenesulfonic acids are used. A table of results is appended giving the % yield of alkaloids from various sources when the above solvents are used.

F. S. HAMMETT.

*Cinchona robusta*. A. GROOTHOFF. *Ind. Merc.* 40, 1025-7(1917); *Chem. Weekblad* 16, 82(1919).—A review of G.'s own investigations and of the work of others on the growth and analysis of the bark of *Cinchona robusta*.

JULIAN F. SMITH.

Recovery of silver from albumose-silver solutions. Methods for the analysis of these solutions. G. MAURE. *Chem. Ztg.* 42, 513-5(1918); *J. Soc. Chem. Ind.* 37, 782-3A.—Large quantities of 0.1% albumose-Ag solns. are now used in certain hospitals and the recovery of the Ag from the used soln. is of importance. The following method is recommended for the purpose: Treat 360 l. of the waste soln. with 60 g. of  $H_2SO_4$  mixed with 200 cc. of water, and add 19 g. of NaCl dissolved in 200 cc. of water; allow the ppt. to settle, collect on a filter, dry, and fuse with a mixt. of  $K_2CO_3$  30,  $Na_2CO_3$  30, and  $KNO_3$  15 g. Pour the mixt. while still fluid into cold water and collect the metallic Ag. The cost of treating 360 l. of the soln. is estd. to be M. 0.12; the wt. of Ag recovered is 33.6 g., having a value of M. 13.75. An alternative method consists in pptg. the Ag with  $NH_4SCN$  in the presence of  $H_2SO_4$ ; the  $AgSCN$  is then treated as described. The estd. cost in this case is M. 0.23. To det. Ag in albumose-Ag soln., the Ag is first pptd. as metallic Ag (by reduction) or as some insol. salt which is fused with alkali carbonate and nitrate, and the Ag is then dissolved in  $HNO_3$  and titrated. Methods using the following reagents yield accurate results: Lactose and NaOH, tannin, HCl, KBr and  $H_2SO_4$ , KI and  $H_2SO_4$ ,  $NH_4SCN$  and  $HNO_3$ ,  $K_4Fe(CN)_6$  and AcOH. Reduction with  $FeSO_4$  or oxidation of the org. matter with permanganate, gives low results.

E. H.

The distribution and characters of some of the odorous principles of plants. FREDERICK B. POWER. *J. Ind. Eng. Chem.* 11, 344-52(1919).—An address. The chem. nature of essential oils, and the general methods for their extn. are discussed briefly. The more important oils are described and grouped according to the families of plants from which they are obtained.

T. G. PHILLIPS.

Note on opium analysis. D. B. DORT. *Pharm. J.* 101, 318(1918).—D. declares probably unwarranted the recommendation of Annett and Singh (*C. A.* 12, 2652) to remove codeine from the lime soln. by means of toluene previous to treatment with  $Et_2O$  and  $NH_4Cl$  (B. P.) so as to avoid the solvent effect of codeine on morphine. Using  $C_6H_6$  in place of toluene, he finds no gain of pure morphine when comparing results with a parallel detn. by the official process.

S. WALDBOTT.

Ghassoul, a Morocco drug. E. M. HOLMES. *Pharm. J.* 101, 317(1918); cf. *C. A.* 13, 770.—H. recalls the fact that in 1875 he identified this drug brought from Abyssinia by Dr. Leared, as a species of *Mesembryanthemum*.

S. WALDBOTT.

**Assay of tablets.** F. RICHARD. *J. pharm. chim.* 19, 5-17(1919).—Two tables summarize results of examn. of 12 com. samples, each of antipyrine and of aspirin tablets as to av. wt., no. per kg., % of the drug and g. per tablet; nature of excipient and of ash, also m. p. of the isolated drug. In 0.5 g. tablets, antipyrine varies from 0.450 to 0.560 g., aspirin from 0.44 to 0.582. French aspirins contain no trace of free salicylic acid. R. exts. aspirin with H<sub>2</sub>O-free Et<sub>2</sub>O; final drying at 100° should not go beyond 2 hrs. M. p., 130-134°; to obtain 135-6°, allow the crystals to "condense" for 3 or 4 days. Quinine tablets, containing 0.2 to 0.25 g. of the basic HCl-salt, are extd. with abs. EtOH or CHCl<sub>3</sub>. Dissolve the evapn. residue in 100 cc. H<sub>2</sub>O and polarize in a 20 cm. tube.  $[\alpha]_D^{20}$ —147.8° (Codex). It is generally between —148° and —155°, due to a small amt. of neutral HCl-salt,  $[\alpha]_D^{20}$ —219.5°. S. WALDBOTT.

**Note on podophyllin.** D. B. DORT. *Pharm. J.* 101, 318-9(1918).—D. recommends an NH<sub>3</sub> test to distinguish the resins of *Podophyllum peltatum* and *P. emodi*. The latter leaves a decidedly higher % of insol., gelatinized residue, upon treatment with dil. NH<sub>4</sub>OH. To 0.5 g. resin add 5 cc. dil. NH<sub>4</sub>OH and 5 cc. H<sub>2</sub>O, stir well, filter after 20 min., wash and dry near 100°. Not more than 0.13 g., i. e., 26% should be obtained, if the resin has been prepd. from the rhizome of *P. peltatum*. That of *P. emodi* would probably yield about 60% under the same conditions. S. WALDBOTT.

**Action of iodine on hypophosphorous and phosphorous acids.** Application to the determination of hypophosphites and phosphites. BOYER AND BAUZIL. *J. pharm. chim.* 18, 321-34(1918).—The detns. are based on the following reactions: (a)  $H_3PO_2 + 2I_2 + 2H_2O = H_3PO_4 + 4HI$ ; (b)  $H_3PO_3 + I_2 + H_2O = H_3PO_4 + 2HI$  (in acid medium only); (c)  $H_3PO_3 + I_2 + H_2O = H_3PO_4 + 2HI$  (in alk. medium only). In detg. hypophosphites, b + c are used. When phosphites are absent, reaction c consumes the same amt. of I as b. In b the speed of the reaction with AcOH is only 1/10 of that when HCl or H<sub>2</sub>SO<sub>4</sub> are employed. A graph shows the progress of I absorption in 1, 3, 7, 12 hrs. with different amts. of H<sub>2</sub>SO<sub>4</sub>. An increase will shorten the time. For reaction c, several graphs are given, showing the speed of oxidation in presence of NaOH, Na<sub>2</sub>CO<sub>3</sub> and NaHCO<sub>3</sub>, also the effect of equimol. amts. of each on the oxidation in 30 min. and in 3 hrs. Only about 33% as much I is absorbed when NaOH is used as when Na<sub>2</sub>CO<sub>3</sub> or NaHCO<sub>3</sub> is used, confirming Bougault (*C. A.* 11, 2643, 2756). The reaction is finished in 30 min. with NaHCO<sub>3</sub>, but not until after 3 hrs. with Na<sub>2</sub>CO<sub>3</sub>. With NaOH, secondary reactions predominate, e. g., formation of NaIO, or of H<sub>2</sub>SO<sub>4</sub> from Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>. An excess of NaHCO<sub>3</sub> does no harm, but it is best to acidify before detg. the excess of I. To det. H<sub>3</sub>PO<sub>2</sub> in hypophosphites, dissolve 1 g. in boiled H<sub>2</sub>O, fill to 100 cc.; to 10 cc. thereof add 10 cc. of 25% H<sub>2</sub>SO<sub>4</sub>, then 30 cc. 0.1 N I. Keep the mixt. in the dark for at least 8-10 hrs., then titrate with Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln. To det. H<sub>3</sub>PO<sub>3</sub> in phosphites, dissolve 1 g. in 100 cc. of H<sub>2</sub>O. To 10 cc. thereof add 10 cc. of 5% NaHCO<sub>3</sub>, then 20 cc. 0.1 N I. After 2 hrs. add 10 cc. of 10% AcOH and titrate with thio soln. The phosphates formed or added may be detd. by Bauzil's method (*C. A.* 12, 919). For control, detn. of total P as H<sub>3</sub>PO<sub>4</sub> may be made. Analyt. results of the examn. of 11 com. samples of hypophosphites and 4 of phosphites are given. Three Na salts of the former showed 92.0, 90.1 and 99.7% NaPO<sub>2</sub>H<sub>2</sub>.H<sub>2</sub>O. S. WALDBOTT.

**Gravimetric determination of glycyrrhizin.** A. ASTRUC AND G. PICHARD. *J. pharm. chim.* 18, 289-90(1918); cf. *C. A.* 12, 1235.—Dissolve 3 g. of licorice ext. dried at 100° in 30 cc. H<sub>2</sub>O containing 5 drops of NH<sub>4</sub>OH and filter. To 20 cc. of filtrate add 2.5 cc. H<sub>2</sub>SO<sub>4</sub> and allow to stand for 24 hrs. Decant the limpid liquid upon a filter, wash the residue with a total of 30 cc. H<sub>2</sub>O, filter and reject the washings. Dissolve the residue with 1 or 2 cc. NH<sub>4</sub>OH soln., pass the soln. through the filter and wash with 10 cc. H<sub>2</sub>O containing 5 drops of NH<sub>4</sub>OH, until the washings are colorless.

Evap. the soln. on a water bath and dry at 100°. Add 0.04 g. per 40 cc. of washings and calc. %.

S. WALDBOTT.

**Alcohol-free head and mouth washes.** P. FLEISSIG. Basel. *Schweiz. Apoth. Ztg.* 56, 681-2(1918).—F. gives the following substitute for "Eau de Botot," used as a mouth wash at the Basel hospital: Al acetate tartrate soln. 100.0, H<sub>2</sub>O 1000.0, tincture of cochineal 20.0, menthol 1.0, dissolved in concd. EtOH 3.0; ol. menthae 2.0; 10 saccharin tablets. Other formulas are quoted.

S. WALDBOTT.

**Examination of a Transvaal croton bark.** HENRY G. GREENISH. *Pharm. J.* 101, 289(1918).—The bark is used by the natives near Delagoa Bay as a remedy for bilious malarial fever. (J. Maberley, 1899.) At Kew Gardens it was identified as *Croton Gubouga* S. Moore. The characteristic taste of the bark is due to an acrid principle causing persistent numbness upon tasting, and redness and irritation when a 50% alc. tincture is applied to the skin. It is very sol. in petroleum spirit, which removed from the bark 2.54% of an acrid fat; Et<sub>2</sub>O then extd. 0.49%, less acrid; CHCl<sub>3</sub> then removed 0.53%, non-acrid. 97% EtOH then extd. 2.71% of acrid substance. No alkaloid was present. The acrid principle, a brownish yellow, viscous oil, is not volatile with steam.

S. WALDBOTT.

**Action of eusol upon certain ligatures and sutures.** D. G. SHELDON. *Pharm. J.* 101, 150(1918).—Samples of linen thread, silk, silkworm gut, catgut (4 kinds), horse hair, silver wire and Kangaroo tendon were partly immersed in freshly prepd. eusol each in a corked tube, and observed for 8 days. S. concludes that eusol, owing to its solvent or destructive action, is unsuitable for continuous use in the presence of all the threads mentioned except linen thread and Ag wire.

Determination of free and carbonated alkalies in alkaline solutions of hypochlorites (PHILIBERT) 7. Synthetic camphor (DUBOSC) 10.

**Active substance from ergot.** A. GAMS. U. S. 1,292,394, Jan. 21. Ergot 1200 g. is finely ground and freed from oil by extn. with petroleum ether. The dried powder is then successively extd. with H<sub>2</sub>O (2 portions of 5 l. each), 2 portions of alc. containing a small amt. of formic acid and with 4 l. alc. (80%) containing 1 cc. concd. formic acid per l. The alc. ext. is freed from alc. and from formic acid by distn. and addition of H<sub>2</sub>O during the distn. and the aq. soln. remaining on evapn. is mixed with charcoal

and filtered, evapd. to a small volume, mixed with alc., filtered and evapd. to dryness. About 250 g. of a yellow-brown hygroscopic powder is obtained which is sol. in  $H_2O$  and has the full action of ergot.

Continuous sulfuric acid sampler. S. A. IONIDES. *Chem. Met. Eng.* 20, 38-9 (1919); illus.—At the British Acetones plant in Toronto two 30-ton Chemical Construction Co. Gilchrist towers were installed to reconcentrate the  $H_2SO_4$  diluted in the regular operation. The coolers for the concd. acid were located below the main operating floor. The method of taking Baumé readings each hr. by dipping samples from the discharge pipe of the cooler and taking hydrometer readings from the dipper had its disadvantages in that acid was splashed on the operator's clothes, breakage of hydrometers was high, and carelessness in taking readings often enough was induced. A simple continuous sampling device consisting essentially of a miniature air-lift with  $1/8$  in. lead pipe was installed. The pipe extended from the discharge pipe of the cooler to 4 ft. above the floor to a sepg. head, from whence the liquid passed down into and through the sampling cup and the foam out through the air outlet pipe to the sampling tray and thence to the storage tanks. To prevent froth forming on the surface of the sampling cup, a trap was inserted between the sepg. head and the sampling cup. The air pipe with a nozzle of  $1/8$  in. was connected to the air supply used for agitating the acid in the concentrators and only a minute flow of air was required to give a steady flow of acid up the lift and through the sampling cup. The important points in the construction were: (1) the relative diams. of the air nozzle and the riser pipe, 1:3; (2) the position of the discharge pipe as near to the top of the sampling cup as possible for easy reading of the hydrometer; (3) the provision of some point at which the flow through the sampler could be observed to insure that a steady flow was passing. The advantages were: (1) the availability to observe the Baumé of the discharged acid at any time; (2) the elimination of acid splashing; (3) the marked reduction in hydrometer breakage. J. L. WILEY.

Manufacture of sulfuric acid by the chamber process. GEO. CHRISP. *Gas J.* 145, 173-5(1919); *Gas World* 70 (Coking and By-Products Section), No. 1802, 13-6 (1919)—“Although  $H_2SO_4$  is not at present regarded as a by-product of the coking industry, the probabilities are that in the future it will be recognized as such, by reason of developments in processes for the recovery of the S compds. in our coal.” The manuf. of acid by the chamber process is described. J. L. WILEY.

Application of electric heating to the concentration of sulfuric acid. S. PAGLIANI. *Ann. chim. applicata* 10, 134-7(1918).—Two general industrial methods of concg.  $H_2SO_4$  are in use: (1) The use of Pb basins and porcelain or quartz dishes with evapn. by the heat of the acid; (2) direct heating of the acid by a current of gas. Method (1) requires a minimum consumption of 18 kg. of coal to obtain 100 kg. of 65.6° Bé acid.

from the corresponding quantity of 50-52° Bé. On the average the consumption is 20%. App. based on method (2) requires only 10%. Systems of Pt vessels (Desmoutis system) require 12-15%. P. in his expts. upon elec. concn. of  $H_2SO_4$  used a tri-phase current and employed 3 electrodes of Pt plates in rectangular sandstone vessels containing 40-50 kg. acid. He found that 43 kw. were required to obtain a cwt. of 65.6° Bé. acid from 52° Bé. acid. The production was increased when closed vessels were used. He recommends quartz vessels, and better yet, enameled Fe vessels. He obtained a yield of 26.6 kg. 65.6° Bé. acid from 38 kg. 52° Bé. in 42 min., or at the rate of 40 kg. per hr. He calcs. that with elec. concn. of  $H_2SO_4$ , 430 kw. produce the same thermal effect as 100 kg. of coke or 180 kg. coal, in fire-concg. app. and concludes that working with elec. heating is better and more convenient than with fire heating, giving a product freer of impurities and in less time. ROBERT S. POSMONTIER.

**Potash in 1917.** HOYT S. GALE AND W. B. HICKS. U. S. Geol. Survey, *Mineral Resources of U. S., 1917*, Part II, 397-481 (Preprint No. 26, published Mar. 13, 1919). E. H.

**Formation of ammonia by heating coke with calcium hydroxide.** R. GLASER. *Feuerungstechnik* 6, 3-8(1917); *Z. angew. Chem.* 31, II, 248(1918); *J. Soc. Chem. Ind.* 37, 621A.—On heating coke with a large excess of  $Ca(OH)_2$  the C completely disappears and a large quantity of H is produced. The yield of  $NH_3$  increases with the temp., amtg. at 1145° to 40% of the total obtainable from the N contd. in the coke. On addition of Ni the yield of H is increased and the yield of  $NH_3$  reaches a max. at 630°, catalytic action of the Ni causing decompn. of the  $NH_3$  at higher temps. At 630°  $CH_4$  is also formed if Ni is present. E. J. C.

**Separation of potassium sulfate from the potash liquors of carbon dioxide factories and process for preventing the formation of this salt.** E. LUHMANN. *Z. ges. Kohlen-säureind.* 23, 471-2, 483-6(1917); *Z. angew. Chem.* 31, II, 331(1918); *J. Soc. Chem. Ind.* 38, 11-2A.—The potash liquors employed in  $CO_2$  factories accumulate impurities, the chief of which is  $K_2SO_4$ , derived from  $SO_2$  present in the gas. In course of time the accumulation of sulfate becomes sufficiently large to interfere with the efficiency of the liquor and obstructions may occur in the plant through the crystn. of the sulfate in the cooler portions. The sulfate can be removed by evapg. the liquor, but it is far better to avoid its formation. This may be done by passing the gas through a scrubbing tower packed with limestone. If the scrubbing is performed by a weak soln. of  $Na_2CO_3$  instead of water, the removal of the  $SO_2$  is more complete, or if soda is not available, a suspension of chalk may be used. E. J. C.

**Heat technology applied to solution and cooling in the preparation of potassium chloride from crude potassium salts.** KRULL. *Kali* 11, 307-16(1917); *Z. angew. Chem.* 31, II, 303(1918); *J. Soc. Chem. Ind.* 37, 731A.—The sepn. of KCl from crude K salts, depending upon the different solubilities of KCl and NaCl at different temps., is essentially a problem of applying and extg. heat. According to the constitution of the crude salts, extn. is effected at 90-130° and the soln. is cooled to 15-25°. Enclosed steam is usually employed in the extn. process, the liquor being warmed to 70° in pre-heaters, and then heated to 90-115° in the extn. vessels. Low-pressure exhaust steam is used. In cooling the liquors, the main object is to produce a high yield of well defined crystals. Heat may or may not be recovered during the process; preferably, the liquor is cooled to a low temp. without the recovery of heat. Salts pptd. at lower temps. are somewhat contaminated with sulfate, but these may be profitably employed in the manuf. of sulfates; on the other hand, the quality of the liquor is improved for use again in the extn. process by the removal of sulfates. The cooling boxes formerly employed yielded a product excelled by no other method; on the other hand, they possessed great

disadvantages in their low output and the necessity for removing the product by hand. Cooling by stages only partly remedied this defect. E. J. C.

**The potash industry of Canada.** E. B. BIGGAR. *Trans. Am. Inst. Chem. Eng.* 10, 85-103.—Up to the development of the Stassfurt deposits  $\frac{2}{3}$  to  $\frac{3}{4}$  the world's potash came from Canadian "pot-ash" and "pearl-ash." Only 500 bbls. per year have been produced in recent times. Discussion brought out methods of inverse multiple-effect evapn. and electrically compressed steam expts. for saving latent heat in chem. engineering work. Western kelp and lake water utilization details are brought out. J. R. W.

**Potash salts in Hungary.** F. VON KONEK-NORWALL. *Chem. Ztg.* 42, 365-7 (1918); *J. Soc. Chem. Ind.* 37, 544A.—Large quantities of alunite occur in Northern Hungary. The  $K_2SO_4$  may be recovered by roasting at a red heat until all the  $Al_2(SO_4)_3$  has been decomposed and  $H_2SO_4$  fumes are no longer evolved. The residual mass consists of  $K_2SO_4$  (14 to 15%), alumina, and frequently a considerable quantity of silica; it forms a white powder and may be used directly on the land, but when it has to be transported for a distance it is more economical to ext. it with water and sep. the  $K_2SO_4$  by crystn. from the soln. The mixt. of alumina and silica may be used in the manuf. of porcelain, or the alumina converted into alum for use in the textile trades, the  $H_2SO_4$  for making the alum being obtained by condensing the vapors which are given off when the original mineral is roasted. E. J. C.

**Utilization of kaolin rich in iron for manufacture of alum or aluminium sulfate.** J. MILBAUER AND F. SKUTIL. *Chem. Ztg.* 42, 525-7 (1918); *J. Soc. Chem. Ind.* 37, 765A.—For the manuf. of alum or  $Al_2(SO_4)_3$  from kaolin contg. a large proportion of Fe, the best method consists on heating the mineral at  $700^\circ$  with the addition of sawdust; air must be excluded during the heating. The calcined material is then heated with  $H_2SO_4$  ( $50^\circ$  Bé., sp. gr. 1.53); the  $FeSO_4$  remains in soln. when the  $Al_2(SO_4)_3$  is sep'd. by crystn. Traces of ferric salts may be removed from the  $Al_2(SO_4)_3$  soln. by adding  $K_4Fe(CN)_6$  and filtering, a small quantity of kieselguhr being added to facilitate the filtration. If, after the Fe salts have been reduced, the  $Al_2(SO_4)_3$  is allowed to crystallize in an atm. free from O, the crystals obtained contain but very little Fe. E. H.

**Production of alumina in the aluminium industry, with special reference to the rotary kiln.** W. VON ESCHER. *Chem. Ztg.* 42, 361-2 (1918); *J. Soc. Chem. Ind.* 37, 544A; cf. *C. A.* 12, 2300.—A type of rotary kiln especially adapted to drying and dehydrating  $Al(OH)_3$  contg. 45-50% total  $H_2O$ , is described. Owing to the high temp. required,  $1500-1550^\circ$ , the kiln differs considerably from the type used in the cement industry. It consists essentially of 5 parts, a feeding device, the kiln proper, a cooler for the hot alumina, an automatic device for weighing and delivering the product into sacks, and a dust-collecting equipment for recovering dust from the escaping gases. The kiln is fired with producer or natural gas, the air being preheated and supplied under pressure. The losses are very small (under 1%). The dehydrated alumina should have a loss on ignition of at most 0.15%. E. J. C.

**The production of nitrogen compounds.** JACK P. MONTGOMERY. *Univ. Alabama. Chem. Eng.* 27, 35-9 (1918).—The various methods in use at present, for the fixation of atm. N and their importance in peace time as well as in war time are discussed.

PHILIP CYRULL.

**The conditions for using the Schilling apparatus for the control of industrial hydrogen.** F. BOURION AND CH. COURTOIS. *Compt. rend.* 168, 232-5 (1919).—In detg. the ascensional force of industrial H by the Schilling app. (based on Graham's law), the calculation as usually made is correct only for the dry gas, whereas the gas is generally satd. with  $H_2O$ -vapor. From detns. made at intervals during a yr., the

authors have prepd. a table of corrections, the application of which gives an abs. value regardless of the gaseous impurity. F. W. SMITHER.

**Recovery of volatile inflammable solvents in industrial operations.** QUIRINO SESTINI. *Bergaus. Ann. chim. applicata* 10, 117-30(1918).—Among the particular operations considered was the continuous treatment of fabrics for rendering them impervious, or treatment with medicating solns. Methods hitherto employed for recovering volatile solvents, generally involving the use of a hood connected with an aspirator, are defective (1) because, depending upon the aspiration of large quantities of air, they recover the solvent with difficulty and leave behind the greater part of it in the state of vapor satg. the aspirated air; (2) because the hoods are placed above the treated and subsequently heated fabrics although the vapors of the solvents employed always have a d. considerably greater than that of air. Detailed procedure and the app. for prepg. gauze impregnated with  $\text{CHI}_3$  with a little colophony and vaseline, and recovering the  $\text{Et}_2\text{O}$  used as solvent are described. For evapg. the solvent recourse was had to elec. heating. Vapors of  $\text{Et}_2\text{O}$  in presence of air and in contact with metallic wires (Fe, Cu, Ni) produce considerable amts. of acid, irritating vapors of an aldehydic odor. Further expts. showed that  $\text{Et}_2\text{O}$  in contact with a metallic surface heated above  $300^\circ$  and in presence of air, oxidized completely to acetaldehyde, and if the air was in greater abundance, to formaldehyde. (S. suggests that this observation be made the basis of a test for traces of  $\text{Et}_2\text{O}$  in other volatile substances, i. e., passing the first vapors produced together with air through a tube containing an Fe wire heated by means of an elec. current.) For the purpose in question, a heating app. consisting of circulating oil of high flask point (transformer oil) was used. Starting from a heater box in which was placed the coil of wire through which passed the heating current, oil circulated from the top of this box down and up through a U-pipe and was raised up into a reservoir high above the level of the oil in the heater box by injected compressed air that enters the ascending branch of the U near the bottom. From this reservoir the oil passed through spiral heating coils of pipe placed in the drying chamber, the cloth passing near the spiral coils. The injected air was the compressed air from the condensing app. of the system and was satd. with  $\text{Et}_2\text{O}$  vapor. The reservoir was open to the drying chamber which had a vol. of  $6 \text{ m}^3$ . There was required  $\frac{3}{4}$  hr. to bring the temp. of the atm. in the chamber to  $60^\circ$ , using 15 kw. of current. For continuous work 10 and later 5 kw. were sufficient. The recovery system consisted of 3 enclosed chambers. The first was small and contained the glass vessel with the  $\text{Et}_2\text{O}$  soln. through which the gauze was passed. The second chamber was the drying chamber with the heating app. above described. The vapors were condensed by 2 coil condensers in series, the first cooled by water and the second by ice. The app. recovered from 50 to 80% of the solvent, averaging 70%. The production of gauze amounted to 5000 m. per day. The  $\text{CHI}_3$  is often slightly altered by the heat, tinting the gauze green. To remedy this, 3% resorcinol is generally added to the soln. Diphenylamine was found to be a good substitute for resorcinol. Later the alteration of the  $\text{CHI}_3$  was found to be due to traces of  $\text{EtHSO}_4$  contained in com.  $\text{Et}_2\text{O}$ , and avoided by neutralizing the  $\text{Et}_2\text{O}$  with alc. alkali. Glycerol was substituted for the vaseline used, improving the quality of softness of the gauze produced, and requiring much smaller quantities. ROBERT S. POSMONTIER.

**Condensation products in Germany.** ANDRE DUBOSC. *Caoutchouc & gutta-percha* 16, 9709-10(1919).—The firm of Truan and Sons, of Hamburg, has published a description of a new insulator, which it has named "Paturau." D. states that this material is none other than Bakelite. JOHN B. TUTTLE.

**Observations on the drying of Indian products.** P. E. VERKADE. *Ind. Merc.* 41, 109-11(1918); *Chem. Weekblad* 16, 79-80(1919).—A discussion of the methods in cur-

rent use for drying various articles, as copra and others, produced in the Dutch East Indies.

The value of sulfur in ores (PAUL) 9. Apparatus for the extraction of liquids in towers filled with Raschig's rings (RASCHIG) 1. Utilization of the ash of pyrites in Italian steel making (LORTI) 9. Graphs for calculating the revivification of spent acids (FOWLER) 24. Flue dust (VOELCKER) 15. The limits of separation by fractional distillation (DURFON) 1.

Nitric acid by oxidation of ammonia. W. S. LANDIS. U. S. 1,292,814, Jan. 28. N oxides for the manuf. of  $\text{HNO}_3$  are obtained by the catalytic oxidation of  $\text{NH}_3$  mixed with sufficient air enriched in O to render the reaction self-sustaining. Using a gas containing 30-40% O (as may be obtained by fractionating liquid air) as the oxidizing medium, a nitrous gas of 12-20% concn. may be obtained by the oxidation of  $\text{NH}_3$ . The latter may be produced by the action of steam on  $\text{CaCN}_2$ .

Concentrating nitric acid. F. C. ZEISBERG. U. S. 1,292,948, Jan. 28. Acid mixts. containing 64% or more of  $\text{H}_2\text{SO}_4$  and from 3% to 25%  $\text{HNO}_3$ , such as spent acids from nitrating cellulose, are treated with a current of hot gases and steam and the  $\text{HNO}_3$  vapors are carried away and condensed. A concg. tower for carrying out this process is illustrated and described.

Concentrated nitrous gases. O. JENSEN. U. S. 1,291,909, Jan. 21. Concd. N oxides are obtained by absorbing dil. nitrous gases in strong  $\text{H}_2\text{SO}_4$  and subsequently driving out nitrous gases from the nitrosylsulfuric acid by heating. The  $\text{H}_2\text{SO}_4$  used is of about 90% strength and with acid of this concn. the acid may be freed almost completely of N oxides by merely heating without the addition of either denitrating substances or of  $\text{H}_2\text{O}$ . Dephlegmation of the vapors from this heating operation is effected by an app. through which the nitrous vitriol flows downwardly to the heating vessel. If  $\text{H}_2\text{SO}_4$  of concn. materially above 90% is used, the denitration of the acid is much less complete, while the use of acid of lower strength lowers the amt. of nitrous gases dissolved by it. By this process of absorption and distn., dil. nitrous gases from an elec. furnace may be obtained as concd.  $\text{N}_2\text{O}_4$  without diln. of the  $\text{H}_2\text{SO}_4$  so that the latter may be immediately reused for absorption. When the concd. gases are absorbed in  $\text{H}_2\text{O}$  with a supply of air,  $\text{HNO}_3$  of 67% concn. is readily obtained. The gases produced are also adapted for use in producing liquid  $\text{N}_2\text{O}_4$ .

Sulfur trioxide. W. H. SEAMON. U. S. 1,292,098, Jan. 21. Equimol. proportions of  $\text{Na}_2\text{SO}_4$  and  $\text{CaSO}_4$  and 2 mol. proportions of  $\text{SiO}_2$  are heated to a temp. sufficient to form Na Ca silicate in a fused condition and liberate substantially all the S present in the form of  $\text{SO}_3$ . This reaction may be effected in a reverberatory furnace (fired with coal, gas or oil) and the gaseous products carrying the  $\text{SO}_3$  are led off to an absorption app. in which the  $\text{SO}_3$  is absorbed in  $\text{H}_2\text{SO}_4$  or  $\text{H}_2\text{O}$ . The flame which comes into contact with the mixt. of sulfates and  $\text{SiO}_2$  should be of a slightly oxidizing character, reducing agents being avoided to prevent formation of  $\text{SO}_2$ . The mixt. of sulfates employed may be the natural deposit of Na and Ca sulfates found in N. Mex.

Separating nitrates from associated impurities. H. S. COX. U. S. 1,292,580, Jan. 28. Niter is recovered from natural deposits or from residues of industrial operations by dissolving the niter from the material at a temp. of 50-70° with a soln. which

is satd., when cold or moderately warm, with niter and with sol. impurities of the niter-bearing material, cooling the soln. thus obtained to produce impure niter crystals, digesting these crystals at a temp. of 100–120° with a soln. which, when cool or moderately warm, is satd. with niter and impurities and then crystg. niter from the soln. obtained by this digestion.

**Soluble compounds of potassium from glauconite.** F. TSCHERNER. U. S. 1,292,929, Jan. 28. Glauconite 2000, is mixed with "limesand" (which contains about 71%  $\text{CaCO}_3$  and 14%  $\text{SiO}_2$ , together with compds. of Mg, Fe, Al and K) 1000–1600 and NaCl 700 parts and the mixt. is finely ground and passed through a rotary kiln in which it is heated to 800–820° to oxidize Fe compds. while avoiding material clinkering or volatilization of K compds. The mixt. is then further heated in a muffle and dropped into a "soaking pit" in which it is allowed to remain for an hr. to permit completion of reactions initiated and the product is afterward leached with  $\text{H}_2\text{O}$  and KCl and NaCl separately crystallized out. Cf. C. A. 12, 2668.

**Removing silica from calcined alunite.** C. H. MACDOWELL and P. R. HERSEMAN. U. S. 1,291,979, Jan. 21. Raw and calcined alunite is freed from silica by mixing it with C and heating the mixt. to a temp. sufficient to volatilize the silica (above 1650°) in an inert atm. NaCl may be added to effect removal of Fe.

**Separating tungsten compounds from solutions.** C. ANDERSON and E. H. WESTING. U. S. 1,292,559, Jan. 28. W is pptd. from solns. such as those of  $\text{Na}_2\text{WO}_4$  or  $(\text{NH}_4)_2\text{WO}_4$  by the addition of a ferric salt and an alkali metal hydroxide, such as  $\text{Fe}_2(\text{SO}_4)_3$  and NaOH, to form ferric tungstate.

**Bromine from gas mixtures.** C. E. MURRELL. U. S. 1,292,016, Jan. 21. Gas mixts. containing Br, *e. g.*, gases from blowing brines with air, are treated with  $\text{NH}_3$  to form a fume of  $\text{NH}_4\text{Br}$  and the fume is pptd. electrically.

**Zinc oxide from ore.** D. B. JONES. U. S. 1,292,330, Jan. 21. Zn ore is formed into spherical briquets with reducing material and the briquets are fed by gravity along an inclined way through a preheating chamber to a furnace, heated sufficiently to expel their Zn contents in the form of vapor and supplied with sufficient air to convert the vapor into  $\text{ZnO}$ .

**Calcining granular materials with gaseous fuel.** C. D. McCOURT. U. S. 1,291,965, Jan. 21. In calcining  $\text{CaCO}_3$ , ores or other granular material, the charge is fed continuously through a furnace chamber and heated by burning within the material an explosive gaseous mixt. fed to the charge at a speed greater than that of backfiring. A reagent such as Cl or HCl may be supplied to the charge in the furnace for effecting chemical reaction with it, *e. g.*, for the production of chlorides of metals in the ore treated.

**Coating valves and cylinder walls of gas engines.** J. F. SMITH. U. S. 1,292,903, Jan. 28. A mixt. for removing C from and forming a smooth coating upon the walls of cylinders and valves of internal-combustion engines is formed of  $\text{ZnO}$  2,  $\text{NH}_4\text{Cl}$  1, and  $\text{H}_2\text{O}$  128 parts. The mixt. is introduced into the engine in small amts. while the engine is running. Small amts. of Venetian red and  $\text{NH}_4\text{OH}$  also may be included in the mixt. A smooth, bright coating is said to be formed on the walls of the engine which improves inequalities of the surface and resists the deposition of C in the cylinders.

**Fire-extinguishing solution of low freezing point.** G. E. FERGUSON. U. S. 1,292,743, Jan. 28.  $\text{CCl}_4$  is mixed with aniline or a similar amino compd. to lower its freezing point. U. S. 1,292,744 relates to the similar use of ethyl benzoate instead of aniline.

**Composition for coating water pipes.** W. A. RUDDELL. U. S. 1,292,964, Jan. 28. A mixt. of paraffin 40, petrolatum 40 and alc. 20 parts is used for coating water

pipes, radiators or tanks to prevent "sweating" or freezing from too rapid cooling on standing.

**Composition for holding diamonds during abrasive treatment.** C. J. COLEMAN. U. S. 1,291,769, Jan. 21. A compn. for use as a matrix for holding diamonds during cutting and polishing is formed of Fe carbide 13, borax 2 and  $\text{WO}_3$  3 parts. The heat developed during the polishing does not cause the diamond to loosen from the compn.

**Adhesive.** A. E. JURY. U. S. 1,292,333, Jan. 21. An adhesive for uniting fabrics is formed of an emulsion containing castor oil, dextrin and  $\text{H}_2\text{O}$ .

## 19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLEININGER.

**Enamels for cast iron.** HOMER F. STALEY. *J. Am. Ceram. Soc.* 1, 703-9(1918); cf. C. A. 13, 253.—*I. Tin enamels:* Two formulas are given for leadless, 2 for low-Pb, and 3 for high-Pb types. All are expressed in 3 ways, batch wts., % compns. and empirical formulas. *II. Antimony Enamels:* Typical formulas are given for 1 leadless, 1 low-Pb, and 2 medium-Pb mixts. using (1)  $\text{NaSbO}_3$  and also (2)  $\text{Sb}_2\text{O}_3$ . The mixts. are practical com. batches. C. H. KERR.

**A method for the determination of air in plastic clay.** H. SPURRIER. *J. Am. Ceram. Soc.* 1, 710-5(1918).—Pug mill treatment may introduce harmful amts. of air. A simple volumetric app. is described. The value of the detn. is shown by the tests in which increase from 9.6 to 13.2% air by vol. was caused by 5 puggings. C. H. KERR.

**Notes on sagger clays and mixtures.** G. H. BROWN. *J. Am. Ceram. Soc.* 1, 716-29(1918).—Causes of sagger failure are described and classified. A good av. mixt. is 50% grog, 20% vitrifying bond clay, 30% open-burning clay. Deformation at kiln temps. is not one of the most important causes of failure. An excess of sandy clay is a common cause of cracking. A small addition of kaolin or similar open-burning clay is often beneficial. For preparing the mixt. a wet pan, preferably with the mullers raised slightly from the bottom is recommended. Drying and first burning are of great importance. C. H. KERR.

**A contribution to the methods of glass analysis with special reference to boric acid and the two oxides of arsenic.** E. T. ALLEN AND E. G. ZIGS. *J. Am. Ceram. Soc.* 1, 739-86(1918).—An accurate method for  $\text{As}_2\text{O}_3$  and  $\text{As}_2\text{O}_5$  is given. The sepn. depends upon the volatilization of trivalent As as  $\text{AsF}_3$  when the glass is heated with  $\text{HF} + \text{H}_2\text{SO}_4$  while the pentavalent As remains in the residue. The latter is pptd. as sulfide, then oxidized to  $\text{H}_3\text{AsO}_4$ , reduced by HI and titrated with a standard I soln. The trivalent As is detd. by difference. Total As is detd. by fusing the glass with  $\text{Na}_2\text{CO}_3$  and  $\text{NaNO}_3$ , removing the  $\text{SiO}_2$  and excess  $\text{HNO}_3$  by evapn. with  $\text{H}_2\text{SO}_4$  and filtering; it is then pptd. as sulfide and treated as above. The iodometric method is preferable to the  $\text{MgHAsO}_4$  method. Chapin's method (cf. C. A. 3, 406) for  $\text{B}_2\text{O}_3$  is reliable. Accuracy is affected by large amts. of  $\text{As}_2\text{O}_3$  but not by  $\text{As}_2\text{O}_5$ . If the  $\text{As}_2\text{O}_3$  is large in amt. the soln. should be oxidized by  $\text{H}_2\text{O}_2$  after making alk. with NaOH and it will not then interfere. For very accurate work large amts. of fluorides interfere but for ordinary work this can be ignored. Details of a method for minute quantities of Fe are given. Ten Jena optical glasses show from 0.011 to 0.020%  $\text{Fe}_2\text{O}_3$  while 4 Am. optical glasses show 0.029 to 0.046%. Details of a method for Zn are given, also methods for the sepn. and detn. of Pb and Ba occurring together and for the sepn. and detn. of Ca or Ba occurring with large amt. of Al and very little Fe. The detn. of  $\text{H}_2\text{O}$  is important in accurate work for carefully prepd. powdered samples of glass show 0.03

to 0.20%  $H_2O$  while 2 samples left in a grinder for several hrs. showed 0.68 and 0.88%  $H_2O$ . Glasses are shown to contain an appreciable amt. of gas, most of which is not included in any way in an ordinary analysis. One Na-Ca glass gave 6.55 cc. gas from 6.577 g. of glass and the gas contained  $O_2$ , 64.2;  $CO_2$ , 24.2;  $CO$ , 3.5;  $H_2$ , 3.9;  $N_2$ , 4.1, in addition to some  $SO_2$ . The occurrence of gases is briefly discussed. The following table shows analyses of important optical glasses:

C. H. KERR.

The condition of arsenic in glass and its role in glass-making. E. T. ALLEN AND E. G. ZIES. *J. Am. Ceram. Soc.* 1, 787-90 (1918).—Schott held that glass never contains As in the  $As_2O_5$  form but always as  $As_2O_3$  if present at all. Rosenhain held the opposite. The authors results show in all glasses tested, both plate and optical, that most of the As exists as  $As_2O_3$ , but a portion exists as  $As_2O_5$ . In glass making As is used for 2 purposes, (1) to "whiten" the glass, a function which is not considered in this paper and (2) to aid in fining. Apparently  $As_2O_3$  is oxidized at low temp. and the product formed is stable enough to remain until a high temp. is reached when it slowly dissociates into  $O_2$  and  $As_2O_3$ , both of which aid fining. Analyses of 3 optical, 1 spectacle and 1 plate glass follow:

| Kind of Glass.                   | % $As_2O_3$ taken. | $As_2O_5$ . | Found. $As_2O_3$ . | Total as $As_2O_3$ . | % $As_2O_5$ lost. |
|----------------------------------|--------------------|-------------|--------------------|----------------------|-------------------|

C. H. KERR.

The baby milk bottle a possible cause of lead poisoning. GUERBET. Rouen. *J. pharm. chim.* 18, 291-3 (1918).—Milk sterilized in certain bottles of crystal glass that were well made and durable, turned yellowish gray, and a brownish ppt. formed, firmly adhering to the inner wall even after rinsing. Chem. detn. of Pb by Meillère's method (*C. A.* 9, 1590) in milk sterilized on the boiling water bath for 20 min. in the incriminated bottles showed from 3 to 9 mg. of Pb per l., while milk bottles of ordinary

glass yielded no Pb to milk. The Pb in the glass is attacked with formation of PbS only in alk. media, or in presence of chlorides. S. WALDBOTT.

**Phosphoric acid glasses and glazes.** H. FRITZ. *Chem. Ztg.* 42, 422(1918); *J. Soc. Chem. Ind.* 37, 655A.—Glasses and glazes were prepd. from mixts. of Pb oxide, alkalis, lime, BaO or ZnO, and  $P_2O_5$  or a phosphate. When a phosphate was used the products were not clear, but when  $P_2O_5$  was used they were mostly clear and occasionally brilliant. In some cases the introduction of 0.15 mol. of  $Al_2O_3$  made a turbid glass or glaze clear. Most of the glazes prepd. with  $P_2O_5$  were subject to "crazing." Brilliant glazes free from crazing were obtained, however, with a mixt. of the compn. (0.1  $K_2O$ , 0.1  $CaO$ , 0.8  $PbO$ ), 0.2  $Al_2O_3$ , 2  $P_2O_5$ . C. H. KERR.

**Silica products.** A. BIGOT. *Chimie & industrie* 1, 712-23(1918); cf. C. A. 13, 778.—Certain gray quartz rocks form a brownish glaze on the surface at  $1650^\circ$ , but if heated to  $1710^\circ$  the glaze is absorbed and the product comes out white and mat. The difference between original Normandy rock (a), and the fine material (b) (what remains in suspension in  $H_2O$  when 200-mesh powder is decanted) is shown: free  $SiO_2$  (a) 95.95, (b) 76.90; combined  $SiO_2$  (a) not detd., (b) 9.50;  $Al_2O_3$  (a) 2.65, (b) 7.60;  $Fe_2O_3$  (a) 1.96, (b) 0.95;  $CaO$  (a) 0.15, (b) 0.35;  $MgO$  (a) 0.08, (b) 0.20; ign. loss (a) 1.20, (b) 3.12;  $CO_2$  (a) not detd., (b) 0.08. This shows about 7-7.5% clay content in the original rock and 21-22% in the decanted part. The decanted part shows 1.5% contraction when burned at  $1250^\circ$  and  $4\frac{1}{2}\%$  at  $1600^\circ$ . At  $1600^\circ$  it is covered by a brownish glaze which remains until fusion. Cones of the original rock ground to 200 mesh deform at  $1720^\circ$  and the addn. of 2%  $CaO$  makes no change; the decanted part deforms at  $1680^\circ$  and the addn. of 2%  $CaO$  lowers the deformation point to  $1630^\circ$ . Products from such rocks are made up of 2 ingredients, (1) the rock grains which expand with temp. increase and (2) the binder which begins to contract at  $1250^\circ$ . Too much  $Al_2O_3$  is harmful, but if the rock contains no  $Al_2O_3$ , a little must be added. In testing raw  $SiO_2$  materials they are heated to  $1710^\circ$ . They should not fuse nor crumble into small particles. Many French quartzites expand between 10 and 15% at  $1710^\circ$ . Those of lower expansion are preferable. D. is detd. by sp. gr. balance. Porosity is detd. by  $H_2O$  absorption.  $SiO_2$  deposits usually vary greatly and such variations in deposits are of greatest importance in manufacturing. It is shown that the gray parts of bricks containing only 85%  $SiO_2$  are as refractory and useful as the part containing 95%  $SiO_2$ , and they are more resistant to crushing. The  $CaO + Fe_2O_3$  in high grade  $SiO_2$  bricks is usually considered excessive over 3-4% but the gray parts contain 10-14%. The following table shows typical data. A = brick, good quality; B = brick which crack at high temp.; C = brick made from rock which crumbles at high temp.; D = brick from Martin furnace, part not attacked; E, like D, brown part; F = like D, gray part:

|                                                                                         | A.           | B.           | C.           | D.           | E.           | F.           |

C. H. KERR.

**Magnesia ware.** TRYGVÆ D. YENSEN. *J. Am. Ceram. Soc.* 1, 730-3(1918).—MgO was fused, crushed and made into crucibles at the Univ. of Wisconsin before 1910. Since 1912 Yensen has been making MgO crucibles regularly. MgO is fused in an arc furnace, crushed to 40-mesh, mixed with 5% Mg(OH)<sub>2</sub>, molded in a steel mold, dried and finally heated to 1800° in an elec. furnace. Impurity is usually about 5%. Crucible manufacturers have not yet taken up com. production. C. H. K.

**Determination of crushing strength of refractory materials.** A. BIGOT. *Chimie & Industrie* 1, 723-6(1918).—The Bodin method was used and the special furnace is briefly described. Test pieces were 20 mm. cubes. Two general classes of materials were found, (1) those showing a decided max. in the strength curve at about 1000°, including SiO<sub>2</sub>, clay, bauxite and SiC mixts., and (2) those showing no max. at 1000°, including MgO, chrome, etc. The curves are remarkable. The nature of failure was observed—with increasing strength toward the max. the breaks were clean cut; with decreasing strength beyond the max. the failure was a sort of flowage much like that of a plastic material. C. H. KERR.

**The partial purification of zirconium oxide.** A. J. PHILLIPS. *J. Am. Ceram. Soc.* 1, 791-800(1918).—Sintering with Na<sub>2</sub>CO<sub>3</sub> was too tedious and not complete enough to give under 0.1% Fe<sub>2</sub>O<sub>3</sub>. Roasting with NH<sub>4</sub>Cl or NaCl was unsatisfactory. Many trials with all sorts of material were made. The final method was to bubble Cl<sub>2</sub> through hot H<sub>2</sub>O and pass it through a vertical retort heated to about 900° containing the zirconia mixed with about 4% finely powdered petroleum coke and molded into small balls. C. H. KERR.

**Zirconia.** Its use as a refractory, an opacifier and an abrasive. A. GRANGER. *Mon. sci.* 9, 5-14(1919).—As a lab. material ZrO<sub>2</sub> is old (Klaproth, 1789), but as a com. product it is very new. The various ZrO<sub>2</sub> ores are described and analyses of 7 are given. The chief ore is zircon. The Brazilian deposit marketed by Foote Mineral Co. is described. Lab. processes for recovering Zr are given. ZrO<sub>2</sub> fuses above 3000° and even with 1.25% SiO<sub>2</sub> + Fe<sub>2</sub>O<sub>3</sub> the m. p. is above 2500°. The coeff. of expansion is  $8.14 \times 10^{-7}$  compared with SiC =  $6.4 \times 10^{-6}$  and alundum =  $7.1 \times 10^{-8}$ . ZrO<sub>2</sub> is very inert chemically and even at 3000° an equimolecular mixt. with SiO<sub>2</sub> shows very little reaction—the SiO<sub>2</sub> has fused and penetrated the ZrO<sub>2</sub>. The most important reaction is its tendency to form carbide, especially in a C elec. furnace. Its sp. cond. changes with temp. from 0.0008 at 1200° to 0.0034 at 1400°. The literature on ZrO<sub>2</sub> as a refractory is exhaustively reviewed (cf. Rieke, C. A. 2, 1746; Wedekind, *Mon. Sci.* 78, 247(1913); Weiss and Lehmann, C. A. 4, 1283; Bayer, *Ibid* 4, 1527; Ruff, *Ibid* 8, 2609; 11, 2633; Podszus, *Ibid* 11, 2838; H. C. Meyer, *Ibid* 12, 9, 362, 2136). The use of ZrO<sub>2</sub> as an opacifier has been studied but little. It is too costly for present use. The cost might be warranted if unusual resistance to acid were developed or other great advantage. As an abrasive it is not especially promising because of its chem. inactivity. The usual silicate bonds are not satisfactory and cement bonds are the only ones available. The chief future of ZrO<sub>2</sub> is in the field of metallurgical refractories. Also in *Chem. News* 118, 115-8, 121-3(1919). C. H. KERR.

**The composition of Chinese celadon pottery.** J. S. LAIRD. *J. Am. Ceram. Soc.* 1, 675-8(1918).—A lump of glaze (a) found on the floor of an old Chinese kiln and the glaze (b) and body (c) of a saucer of the Yuan period analyzed: SiO<sub>2</sub> (a) 72.52, (b) 66.40, (c) 63.20; Al<sub>2</sub>O<sub>3</sub> (a) 10.59, (b) 13.88, (c) 28.30; Fe<sub>2</sub>O<sub>3</sub> (a) 0.41, (b) 0.30, (c) 3.47; FeO (a) 2.02, (b) 1.19, (c) —; CaO (a) 8.48, (b) 11.58, (c) 2.05; MgO (a) 1.24, (b) 1.61, (c) trace; K<sub>2</sub>O (a) 3.77, (b) 4.25, (c) 1.98; Na<sub>2</sub>O (a) 1.48, (b) 1.84, (c) 0.37; MnO (a) trace, (b) trace, (c) trace; TiO<sub>2</sub> (a) trace, (b) trace, (c) trace; P<sub>2</sub>O<sub>5</sub> (a) 0.21, (b) —, (c) trace. Other analyses previously published by Vogt are given. C. H. KERR.

**Notes on certain characteristics of porcelain.** A. V. BLEININGER. *J. Am. Ceram. Soc.* 1, 697-702(1918).—The wide variation in physical properties are explained by the various stages of development in the different types. In low-fired porcelains (about cone 10) the amt. of undissolved quartz is large and that of sillimanite small. Sanitary ware manufacturers use French flint, not quartz, which is a partially amorphous form of  $\text{SiO}_2$  that inverts to cristobalite more quickly than quartz and probably dissolves more readily in fused feldspar. "Dunting" may be due to quartz inversions. In elec. porcelain probably the % free quartz must be low to give max. stability. Expts. replacing quartz by clay and by synthetic sillimanite showed increased stability, high mechanical strength, increase in firing range and sounder bodies. Other minerals not subject to transformations were also promising.  $\text{ZrO}_2$  was especially good for mechanical strength. Expts. showed that feldspar is the important factor in lowering elec. resistance at the temps. used in the tests, 200-500°. For high-tension wares the feldspar content must be low. For the most severe elec. and heat conditions both quartz and feldspar should be eliminated from the body. C. H. KERR.

**Photographic study of porcelain insulators.** H. G. TUFTY. Univ. Wis. *Elec. World* 73, 268-71(1919).—A study of the microstructure of insulator sections under normal and polarized light showed that the quartz is unaffected by any firing temp. and remains practically const. in all types. The use of some high-fusing feldspar in the place of quartz is suggested. The porosity of all sections was very low. Even in the overfired case it was only 4.7%. No crystal other than quartz was found, disproving the theory that crystn. is often the cause of deterioration. The % of unfluxed feldspar seems to have some relation to the quality of the insulator. The poorer quality insulators have a low % while the good insulators have almost double the % of unfluxed feldspar. Conclusions are only general as the history of the specimens was vague. W. E. RUDER.

**Tests of hollow building tile.** BERNARD D. HATHCOCK AND EDWARD SKILLMAN. Bur. of Standards, *Tech. Paper* 120.—The principal tests discussed are those of compression and absorption which together total about 250. Strain readings were taken upon some of these with an 8-in. Berry strain gage for detg. the limit of proportionality and the moduli of elasticity. Besides the compressive strengths and moduli of the tiles, the results show the relationships existing between the moduli of elasticity and the compressive strengths, the colors of the tiles and their compressive strengths, the colors of the tiles and their moduli of elasticity, the percentages of absorption and the compressive strengths, and the percentages of absorption and the colors of the tiles. E. H.

**A discussion of terra cotta dryers.** ELLIS LOVEJOY. *J. Am. Ceram. Soc.* 1, 667-74(1918).—There is great lack of uniformity in dryers and drying methods. The essentials are the use of waste heat, thorough circulation, and humidity control. No present dryer includes all of these. C. H. KERR.

**Operation of continuous kilns.** R. SEYDEL. *Tonind. Ztg.* 42, 482-3(1918); *J. Soc. Chem. Ind.* 37, 622-3A.—The chief difficulties in the operation of a continuous kiln are due to the irregular passage of the air and hot gases through it. This is particularly the case with Hoffmann kilns in which the fuel is burned in hollow pillars formed by the bricks to be burned. If sufficient care be taken to obtain a uniform draught in various parts of the kiln, various auxiliary methods, such as boxing tiles, are unnecessary. Difficulties arise when the finishing point and the point of collapse of the goods lie too close together; the admixt. of fireclay may help to overcome this objection. In a Hoffmann kiln with a tunnel 240-300 ft. in length, of a suitable width, with rounded ends of the same cross-sectional area as the straight portion, and provided with suitable hot-air flues, the fire should travel round at the rate of 33 ft. per

24 hrs. Excellent results may be obtained without difficulty in a wide kiln, with 5 or 6 feed holes, 3 ft.-4 ft. 6 in. apart, and the setting and drawing of the goods is easier than in a narrow kiln. It is important that the area of the rounded ends should be sufficiently large; the reduction usually made at this part of the kiln causes many difficulties in working. The discharge of black smoke from the chimney is an indication that fuel is being applied too soon, or that the air is not hot enough for complete combustion. Sometimes the air is too cool because too much is passing through the kiln; on reducing the quantity no smoke is produced. E. J. C.

Glass for cutting off ultraviolet rays. W. C. TAYLOR. U. S. 1,292,147, Jan. 21. Glass for absorbing ultraviolet rays is formed with  $\text{TiO}_2$  as an essential constituent. The glass batch may, e. g., be made up of sand 49-60, soda 21.75-25, niter 4.6-5.2,  $\text{CaCO}_3$  0-6,  $\text{TiO}_2$  4.25-8, Ce nitrate 0-7.7, V oxide 0-0.35, borax 0.67-1 and arsenic 0.4-0.5 part. A clear, brilliant yellow or yellow-green glass is produced suitable for optical uses. U. S. 1,292,148 relates to a similar glass produced from a batch containing 0.8-1% of  $\text{V}_2\text{O}_5$ , other constituents similar to the formula of the preceding pat. and 0.5% of oxide of Mn, Co, Ni or U.  $\text{TiO}_2$  may be used or may be omitted.

"Antislipping" ceramic tile. G. N. JEFFSON and C. F. DIETZ. U. S. 1,292,953, Jan. 28. Fused granules of  $\text{Al}_2\text{O}_3$  of different sizes are embedded in a ceramic clay mixt. in making "anti-slipping" tiles.

## 20. CEMENT AND OTHER BUILDING MATERIALS.

C. N. WILEY.

New researches on cement. K. ENDELL. *Z. angew. Chem.* 31, I, 233-4, 238-40 (1918); *J. Soc. Chem. Ind.* 38, 76A(1919).—A survey of German literature on cement published during the past ten years. The raw materials for port. cement do not require special investigation beyond that necessary to secure the correct ratio of  $\text{CaO}:\text{SiO}_2 + \text{Al}_2\text{O}_3 + \text{Fe}_2\text{O}_3$  in the finished product. Only glassy blast-furnace slags, which have been cooled rapidly and granulated, can be used for slag cement. If cooled slowly they fall to a useless cryst. powder. The constitution of port. cement clinker is not definitely established. Cobb has shown (*C. A.* 4, 1092, 1532, 1657, 1798, 2193, 2556) that  $\text{CaCO}_3$ ,  $\text{SiO}_2$  and  $\text{Al}_2\text{O}_3$  can react at 800-1200° without fusion, forming Ca silicates at temps. much below the eutectic temp. Na, Mg, Zn, and Ba silicates and aluminates may also be prepared in similar manner. The incompletely burned and unsintered product in the manuf. of port. cement, though largely sol. in *N* HCl, contains silicates and aluminates which are absorbed on heating to a higher temp. by the ternary and quaternary eutectic formed. Jesser and Dittler (cf. *C. A.* 5, 775) observed first an absorption of heat (i. e., fusion of a eutectic) when cement mix was sintered at 1250-1380°, and the crystn. of the chief constituent did not occur until the material had been

heated to a higher temp.; this crystn. was accompanied by evolution of heat. The triangular diagram summarizing the researches at the Geophys. Inst. at Washington (cf. *C. A.* 5, 1982; 9, 702) is reproduced but it is suggested that, as equil. is seldom reached in burning cement clinker, the phases indicated in the triangular diagram may not occur in com. cement. The influence of Fe oxide, MgO, alkalies, and SO<sub>3</sub> on the position of the various areas in the diagram has not been investigated, though it is known that small percentages of FeO and Mn oxide prevent "dusting." Killig produced sufficiently large amts. of pure Ca aluminates to permit the examn. of their mechanical properties. He confirmed the known high crushing strength of aluminous cement, but found that tri-Ca aluminate expands after being mixed with H<sub>2</sub>O, and suggested that this substance does not occur in good port. cement. The setting and the hardening of cement have been studied microscopically by Ambronn (*C. A.* 5, 776), Kiesermann (*C. A.* 5, 1328), Blumenthal (*C. A.* 8, 2048), and Scheidler (*C. A.* 10, 105). A 0.2% soln. of alizarin orange or cryst. alizarin in dil. ammonia was used to identify lime, a similar soln. of cyanin and chromotrop 2R was used to identify alumina, AcOH for combined SiO<sub>2</sub>, and neutral methylene blue for free silica. After the cement and water had been in contact for 2-3 hrs., hexagonal plates of Ca aluminate were visible around the cement grains; these plates were free from silica. Fine needles of Ca silicate were also formed. After 2-4 days, large, hexagonal crystals of Ca(OH)<sub>2</sub> appeared; in contact with the air these formed spherulites of CaCO<sub>3</sub>. Simultaneously, a gelatinous Ca silicate was formed. It was found that these substances are not simply the hydrated products of compds. present in the clinker, but are new compds. formed by the decompn. of the clinker by the water. The hardening of cement appears to be due to the formation and crystn. of Ca aluminate and silicate and to a gelatinous C silicate which unites the crystals present. The increase in vol. during hardening has been shown by Jesser to be due to the tension of aq. vapor in the air. In regard to the destruction of cement by water, etc., sulfates are harmful, but chlorides are negligible. The absorption of the SO<sub>3</sub> radical from sulfates causes large expansion of the cement and leads to its destruction. Synthetic Ca Al sulfate is decompd. by NaCl, MgCl<sub>2</sub>, and sea water and its formation in sea water is therefore improbable. The expansion of cement in sulfate solns. increases with its content of alumina. Prolonged exposure to the air previous to immersion in the sulfate soln. reduces the expansion, possibly on account of the decompn. of the Ca silicate and hydroxide by the CO<sub>2</sub> in the air. When cement is immersed in a magnesia soln., an equiv. amt. of lime is replaced by magnesia.

C. N. WILEY.

Calcium aluminium sulfate as a concrete destructor. NITZSCHE. *Z. angew. Chem.* 31, I, 195-6(1918); *J. Soc. Chem. Ind.* 37, 734-5A.—A discussion of the formation of the double sulfate of Ca and Al in cement and its deleterious action. The compd. is always formed when a soln. of a sulfate is brought into contact with lime water and pptd. alumina, but it is only stable in presence of free lime. Most natural waters contain sulfate and consequently attack cement, but sea water appears not to lead to the formation of the double Ca Al sulfate. The preventive measures recommended are the coating of the cement with bituminous material, or the modification of the constitution of the cement in such a manner as to prevent the formation of the double sulfate.

E. J. C.

Concrete as a chemical engineering material. M. TOCH. *Chem. Met. Eng.* 20, 222-3(1919).—Editorial review of some of the defects of concrete construction. General summary is given of the types of waterproofing used and methods of protection of concrete against erosion, chemical action, disintegration and decompn.

H. A. BRIGT.

The hydraulic properties of the calcium aluminates. P. H. BATES. *J. Am.*

*Ceram. Soc.* 1, 679-96(1918).—In the  $\text{CaO-Al}_2\text{O}_3\text{-SiO}_2$  system the compds. are  $\text{CaO.SiO}_2$ ,  $3\text{CaO.2SiO}_2$ ,  $2\text{CaO.SiO}_2$ ,  $3\text{CaO.SiO}_2$ ,  $3\text{CaO.Al}_2\text{O}_3$ ,  $5\text{CaO.3Al}_2\text{O}_3$ ,  $\text{CaO.Al}_2\text{O}_3$ ,  $3\text{CaO.5Al}_2\text{O}_3$ ,  $\text{Al}_2\text{O}_3.\text{SiO}_2$ ,  $\text{CaO.Al}_2\text{O}_3.2\text{SiO}_2$ ,  $2\text{CaO.Al}_2\text{O}_3.\text{SiO}_2$ ,  $3\text{CaO.Al}_2\text{O}_3.\text{SiO}_2$ . Some exist in several cryst. forms. Burnings were made of all, but only  $2\text{CaO.SiO}_2$  ( $\beta$ -form),  $3\text{CaO.SiO}_2$  and all of the aluminates except  $3\text{CaO.Al}_2\text{O}_3$  developed hydraulic properties. It is a striking fact that  $3\text{CaO.Al}_2\text{O}_3$ , the only aluminate present in portland cement, is not hydraulic. If  $\text{CaO}$  be present also the mix with  $3\text{CaO.Al}_2\text{O}_3$  develops good properties. The compd.  $5\text{CaO.3Al}_2\text{O}_3$  sets very rapidly. Both  $\text{CaO.Al}_2\text{O}_3$  and  $3\text{CaO.5Al}_2\text{O}_3$  set slowly, but harden rapidly, developing great strength in 24 hrs. With 55 to 75%  $\text{Al}_2\text{O}_3$  in  $\text{Ca}$  aluminate burns, a very good cement results. The chief com. drawback is the lack of a widely distributed supply of  $\text{Al}_2\text{O}_3$ . C. H. KERR.

**Decarbonation of dolomite limestone in the rotary kiln.** E. E. EAKINS. *J. Ind. Eng. Chem.* 11, 340(1919).—The contents of a 150-ft. producer-gas-fired rotary kiln were analyzed during a shut-down to det. progress of calcination, results being checked by microscopic examn. and use of White's reagent. Decompn. of  $\text{MgCO}_3$  began about 100 ft. from discharge end, of  $\text{CaCO}_3$  between 30 and 40 ft. and was complete in the last 10 ft. No detns. of temp. could be made. J. S. LAIRD.

**Importance of the valuation of plaster.** E. LINK. *Tonind. Ztg.* 42, 525-6(1918); *J. Soc. Chem. Ind.* 37, 657A.—Heavily adulterated plasters and some plaster substitutes are now on the market in Germany. One of the former examd. by L. was found to consist of plaster of Paris 38.59%,  $\text{CaCO}_3$  20.18%, hydrated lime 39.65%, magnesia 0.45%, and insol. residue 1.12%. It appears to have been made by mixing plaster of Paris with dry slaked lime, the latter having absorbed  $\text{CO}_2$  from the air. Its compn. explains its peculiar behavior when sprinkled into water, the low strength of the plaster, and its softness when set. E. J. C.

**New ingredients for mortar.** H. KÜHL. *Tonind. Ztg.* 42, 17-8, 37-8, 53-4 (1918); *J. Soc. Chem. Ind.* 37, 623-4A.—K. repts. on the use of pure, hydrated lime and hydrated cement (Mühlen, Ger. pats. 293,825 (C. A. 11, 2954) 300,397 and 301,118; cf. *J. Soc. Chem. Ind.* 35, 1109) as ingredients of mortar. Tests of mortar made with hydrated lime (produced by passing slaked lime through an air-separator) showed no expansion. Lime-sand bricks made with this lime are much stronger than those made with ordinary slaked lime. Pure hydrated lime should also meet a wide-felt want in the plaster trade. The coarser siliceous and aluminous particles which are removed from slaked hydraulic lime by an air-separator, yield a good bag lime when ground with quicklime, provided that the additional slaking required by such limes is properly effected. Calcined marl or cement-slurry which has been burned with an excess of lime and then hydrated by steam also produces a non-expanding mortar. The setting time varies with the % of lime and the mode of prepn. of the material. The samples examd. passed the standard tests and also the boiling and hot-water test satisfactorily. Tests of the tensile strength were also satisfactory considering the high % of lime. These new ingredients facilitate the prepn. of new kinds of dry mortars, e. g., mortar of pure hydrated lime, cement mortars, and various mixts. for reinforced concrete. E. H.

**Increasing the resistance of wood paving blocks.** W. RITTER. *Bitumen* 15, 148-50(1917); *Z. angew. Chem.* 31, 308(1918); *J. Soc. Chem. Ind.* 37, 768A.—Wood paving blocks in busy streets require renewal every 5-6 years; attempts have been made to increase their strength by suitable impregnation. Tests were made of crushing resistance calcd. per sq. cm. on prismatic blocks 75.75 sq. mm. in base-area and 120 mm. in height, the pressure being applied in the direction of the fibers. Expts. in which  $\text{Na}$  or  $\text{K}$  carbonate and  $\text{Na}$  silicate in various proportions were added to an impregnating bath of pine wood tar showed no advantage, but increasing the temp. of the bath with

the dry samples gave a 12% increase in strength. Expts. were also made by substituting heavy coal-tar oil for the wood tar at temps. from 112 to 140°. At the higher temp. these trials gave as good results as those with wood tar, but the blocks impregnated at the lower temp. showed a crushing resistance inferior to that of the untreated blocks. Na<sub>2</sub>CO<sub>3</sub> alone, or still better Na silicate alone, gave more favorable test results than the mixt. of carbonate and silicate. The chem. compn. of the impregnating bath, however, is of less importance than its temp. The temp. should not be carried above 200° on account of the danger of splitting the blocks. The best strengthening results are obtained by impregnating for 3 hrs. with gradual increase of temp. up to 200°. A test block showed a crushing strain of 323 kg. per sq. cm. in the untreated condition; this was increased by impregnation at 100° to 330 kg., at 120° to 345, at 140° to 487, at 150° to 516, and at 200° to 536 kg. ## 21. FUELS, GAS, TAR AND COKE.

J. D. PENNOCK.

Fuel economy in the boiler-house. II. JOHN B. C. KERSHAW. *Chem. Met. Eng.* 20, 241-5(1919); cf. C. A. 13, 782.—K. gives illustrations and descriptions of the following automatic CO<sub>2</sub> recorders: Ados or Sarco, Uehling, Simmance-Abady, Cambridge Bi-Meter, Auto, and Mono; and also of the Webster W. R. Combustion Indicator, which is an automatic continuous CO<sub>2</sub> testing app. without any recording device. The Mono Recorder can be used for CO<sub>2</sub>, O, or CO.

III. *Ibid* 291-5. K. describes German types of CO<sub>2</sub> recorders, including the Arndt Gas Balance, the Krell, the Telezometer, the Haber-Loewe Refractometer, and also the thermoscope, this latter not being continuous nor recording in its action. These instruments depend upon the exact measurement of some physical const. of the mixed gases, and are more adapted for scientific observations than for regular use in the boiler house. K. advises checking the results of automatic recorders by occasional analyses of the waste gases, and suggests in this connection the use of an improved Orsat app. and an automatic sampling app. Illustrations of the instruments described are included.

A. G. BLAKELEY.

Methods for more efficiently utilizing our fuel resources. XXVII. Fuel for the merchant marine. F. P. COFFIN. *Gen. Elec. Rev.* 22, 200-12(1919); cf. C. A. 13, 1416.—The necessity of fuel conservation and the installation of all possible labor-saving devices to meet competition in the handling of the world's commerce is noted. Fuel-oil resources are inadequate and the possibilities of using pulverized bituminous coal, pulverized semi-coke, granulated bituminous coal, and granulated semi-coke are discussed, also the means of prepn., advantages and disadvantages of each. Disadvantages of prepg. the fuel on ship board are: the wt. and space required for the pulverizer and for the elevator; the attention required for their operation and maintenance; the coal handling from the bunkers; and the continuance of the dirt nuisance during coaling. By proper diffusion each particle may be surrounded with sufficient air for complete combustion of all available combustible matter, regardless of the % of non-combustible. "Clinkering" or "honeycombing" formation may be chem. or by fusion. "Hard clinker" is formed by the direct melting of some of the ash content and gives little trouble. "Soft clinker" is formed by the slagging of the ash and is either pasty or fluid, and grows steadily. "Honeycomb" is formed by the condensation or coking of tarry

matter as it strikes against the fire-box sheets and results in the accumulation of a soft, light ashy substance spreading over some of the refractory or metal parts of the furnace.  $\text{FeS}_2$  reduces during combustion to  $\text{FeS}$  which is easily fusible. Incomplete combustion yields  $\text{FeO}$  which unites with  $\text{SiO}_2$  to form a honeycomb; whereas  $\text{Fe}_2\text{O}_3$  combines to form a highly infusible clinker. Increases in  $\text{SiO}_2$ ,  $\text{Al}_2\text{O}_3$ , and  $\text{MgO}$  in the fuel tend to decrease, while increases in  $\text{Fe}$ ,  $\text{CaO}$ ,  $\text{K}$ , and  $\text{Na}$  tend to increase the fusibility of the ash. The handling and storage of powdered fuel, the means of filling and emptying bunkers, means of feeding burners, bunker capacities, etc., are discussed. W. H. B.

**Determination of ash of coal.** H. MASTBAUM. *Chem. Ztg.* 42, 385-6, 391-2 (1918); *J. Soc. Chem. Ind.* 37, 567 A.—Incineration in a muffle-furnace does not always give the same result in the detn. of the ash of coal as is obtained when the sample is ignited over a Bunsen burner; the latter method always gives a higher result when the coal contains much  $\text{CaCO}_3$ , since this is not decomposed completely and at the same time S compds. are absorbed from the products of combustion of the gas. If a muffle-furnace is not available, the coal should be ignited over a spirit flame or in an elec. furnace. For com. purposes, it is desirable that the method of detg. the ash of coal and the temp. employed should be prescribed. E. J. C.

**The determination of water in lignite.** G. A. BRENDER & BRANDIS. *Bruinkool* 1918, Nos. 5 and 6; *Chem. Weekblad* 16, 51 (1919).—The detn. of water in lignite as the loss in wt. on drying at  $103^\circ$  is inaccurate because at that temp. lignite gives off  $\text{CO}_2$ , even in an atm. of N, and also absorbs O from the air. The method is good enough for technical work, however, since the errors tend to compensate each other. Accurate results can be obtained by drying at  $100-5^\circ$  in a current of N (dried over  $\text{CaCl}_2$ ), absorbing the water in  $\text{CaCl}_2$  tubes and weighing. Distn. with petroleum or xylene to  $140^\circ$  (several times repeated), and catching the distillate in a buret, is also an accurate method. Dry lignite is extremely hygroscopic. JULIAN F. SMITH.

**Distillation of lignite.** G. A. BRENDER & BRANDIS. *Bruinkool* 1918, No. 12; *Chem. Weekblad* 16, 50 (1919).—Small scale distn. of lignite yielded  $\text{NH}_3$  at the rate of 3.7 kg. per ton, and 3.6% of tar which contained only small amts. of paraffin hydrocarbons. Distn. at low temp., rising slowly to  $400^\circ$ , yielded 7.5% of tar containing 13.1% of paraffins. This is lower than the usual yields from good grade lignite. Yields were calcd. on the basis of water- and ash-free lignite. JULIAN F. SMITH.

**Estimation of cyanogen compounds in concentrated ammonia liquor.** PERCY E. SPIELMANN AND HENRY WOOD. *J. Soc. Chem. Ind.* 38, 43-51 (1919).—As an improved method for the estn. of cyanogen compds. in concd.  $\text{NH}_3$  liquor from points of view of accuracy, ease and rapidity of execution, the following scheme is recommended. (1) Conversion of the  $\text{NH}_4\text{CNS}$  into  $\text{Fe}(\text{CNS})_3$  and measurement of the depth of color obtained. (2) Interaction of a further quantity of the original liquid with  $\text{NH}_3$  polysulfide, whereby the  $\text{NH}_4\text{CN}$  originally present is converted into the thiocyanate, and the estn. of the total  $\text{NH}_4\text{CNS}$  as  $\text{Fe}(\text{CNS})_3$ . The increased quantity found over and above that found directly (without polysulfide treatment) is a measure of the quantity of cyanide present. The presence of ferrocyanide compds. causes no complication, as the conversion of any proportion of ferrocyanide into thiocyanate by the polysulfide soln. can be avoided. A tintometer is used to measure depth of color. J. H. YOUNG.

**Theory of water-gas formation.** GWOSDZ. *Z. angew. Chem.* 31, I, 137-40 (1918); *J. Soc. Chem. Ind.* 37, 538A.—Expts. were made to ascertain the parts played in water-gas formation by the supposed primary reactions (1)  $\text{C} + \text{H}_2\text{O} = \text{CO} + \text{H}_2$ , and (2)  $\text{C} + 2\text{H}_2\text{O} = \text{CO}_2 + 2\text{H}_2$ , and the secondary reactions (3)  $\text{C} + \text{CO}_2 = 2\text{CO}$ , and (4)  $\text{CO} + \text{H}_2\text{O} = \text{CO}_2 + \text{H}_2$ . Superheated steam was passed over various forms

of heated C and the compn. of the issuing gases detd. The temps. varied from 855° down to 560°, and the speed of the current of steam was also varied. Natural forms of C contg. ash in appreciable quantities behaved in a markedly different manner from purified C almost free from ash. With gas coke (8.5% ash) and wood charcoal (1.4% ash) a considerable proportion of CO<sub>2</sub> was always formed (up to 29%). On the other hand lamp C (0.1% ash) at temps. down to 600° gave mixts. closely resembling water-gas as manufd. Even at 500° the mixt.: —CO<sub>2</sub> 8.6%, CO 39.5%, H<sub>2</sub> 40.0%, residue 11.9% was obtained. It is concluded that reaction (2) cannot be a primary reaction, because reaction (3) is known to be too sluggish to account for the formation of the % of CO found at these low temps. It is also concluded that reaction (1) is the primary reaction of water-gas formation, and that the CO formed reacts with the excess of steam tending to establish the water-gas equil., and that this reaction is catalytically influenced by the finely divided ash in the C. E. J. C.

Coke and coal as fuel for gas producer. D. J. STUDLER. *Stahl u. Eisen* 38, 765-9(1918); *J. Soc. Chem. Ind.* 37, 615A.—Markgraf (*Stahl u. Eisen* 36, 1245(1916)) found that gas from a coke producer was less effective than that from a coal producer in open-hearth steel furnaces. S. has collected data on the compn. of gas from producers fired with coke and coal resp., and shows by calcs. that in general when working under similar conditions, gas from coal is more efficient in use than is that from coke, since less air is required for its combustion, and higher temps. may be attained. E. H.

Analysis of spent purifying materials from gas works. WENTZEL. *Z. angew. Chem.* 31, 176(1918); *J. Soc. Chem. Ind.* 37, 653-4A.—W. criticizes the agreement recently made between the Deutsche Gold und Silberscheideanstalt and the German gas works (*C. A.* 12, 2429). He contends that a quantity of 25 g. is far too little to afford a good av. sample for the detn. of moisture. The abs. moisture content of the material cannot be accurately detd. on account of the decompn. of the ferrocyanide, and many large gas works base their results on the air-dried material. The method proposed for the detn. of crude S is criticized on account of the large inaccuracies of the volumetric methods of measurement adopted and the high volatility of the solvent (CS<sub>2</sub>) employed. On the other hand, the Drehschmidt method is said to be satisfactory and accurate, being based on gravimetric principles; differences up to 6% of S have been found by the 2 methods and always settled in favor of the Drehschmidt method. The oxidation by fuming HNO<sub>3</sub> presents no difficulties and with 0.5 g. of substance may be completed within 4 hrs. with a consumption of not more than 30 cc. of acid. In the new method about 240 cc. of CS<sub>2</sub> is consumed per analysis, whereas in the Drehschmidt method about 50 cc. is used and immediately recovered by distn. E. J. C.

Examination of spent gas-purification masses. A. MÜLLER. *Chem. Ztg.* 42, 457(1918); *J. Soc. Chem. Ind.* 37, 690A.—The suggested conventional method of detg. S and cyanogen (Prussian blue) in the spent purification sludge from gas-works (*C. A.* 12, 2429) is open to criticism. In the detn. of the S errors may easily result during the measuring of the CS<sub>2</sub> soln., while there is no proof that extn. of the S is complete. In M.'s experience Drehschmidt's method of extn. (*J. Gasbel.* 1892, 269) is much more trustworthy and rapid. The extn. crucible is a cylindrical porcelain vessel with a perforated bottom, upon which is placed a layer of glass-wool and a compact layer of asbestos. From 15 to 20 g. of the sample is dried in this crucible at about 80° until const. in wt., the crucible then introduced into the extn. app., and the S extd. with about 70 cc. of CS<sub>2</sub>. For the detn. of Prussian blue Feld's method (*J. Gasbel.* 1904, 545) is more rapid and accurate than Knublauch's method (*J. Gasbel.* 1889, 450-9, 493-500) based on the interaction of Cu sulfate and K<sub>4</sub>Fe(CN)<sub>6</sub>; 2 g. of the spent material is triturated in a mortar with 1 cc. of FeSO<sub>4</sub> soln. (278 g. per l.) and 5 cc. of

NaOH soln. (320 g. per l.) and, after 5 mins., 30 cc. of  $MgCl_2$  soln. (610 g. per l.) is slowly stirred in, and the whole washed into a distn. flask with sufficient hot water to make up about 200 cc. After about 5 min. 100 cc. of boiling  $HgCl_2$  soln. (27.1 g. per l.) is added to the boiling liquid, and the boiling continued for about 10 mins. The flask is then connected with the distn. app., the receiver of which is charged with 20 cc. of NaOH soln. (80 g. per l.), and after the introduction of 30 cc. of dil.  $H_2SO_4$  (392 g. per l.), the liquid is distd. for about 20 to 30 mins. The distillate is made up to 250 cc., a trace of  $PbCO_3$  being added to remove any turbidity due to S, and 100 cc. is treated with 5 cc. of KI soln. (41.5 g. per l.) and titrated with 0.1 N  $AgNO_3$  soln., 1 cc. of which is equiv. to 0.009556 g. of Prussian blue,  $Fe_7(CN)_{14}$ .  
E. J. C.

**Determination of the free sulfur content of spent oxide.** N. T. TWISSELMANN. *Chem. Ztg.* 42, 588(1918); *J. Soc. Chem. Ind.* 38, 40-1A; cf. C. A. 13, 782 and preceding abstract.—Five g. of the finely powdered material is extd. for 1.5 hr. with  $CS_2$ , the solvent is then distd. from the ext., the residue of impure S dried at  $100^\circ$ , and weighed. The residue is then dissolved in  $CS_2$ , the soln. filtered, the filtrate evapd., the residue dried at  $100^\circ$ , weighed, and ground to a fine powder; 0.5 g. of this powder is ignited in a porcelain crucible until S has volatilized, and the non-volatile residue is weighed and its weight deducted from that of the impure S.  
E. J. C.

**Analysis of lignite tar from vertical retorts.** L. J. TERNEDEN. *Bruinkool* 1918, No. 4; *Chem. Weekblad* 16, 50-1(1919).—Lignite tar, distd. from vertical retorts in ordinary com. practice, was sepd. from all solids, washed with NaOH and dil.  $H_2SO_4$  and distd. It gave clear, pale yellow oils in fractions: 5.4% to  $170^\circ$ , 12.2% at  $170-230^\circ$  and 15% at  $230-70^\circ$ . The middle fraction was an excellent fuel oil. All 3 contained considerable amts. of unsatd. hydrocarbons. The tar contained 8.4% of paraffin hydrocarbons.  
JULIAN F. SMITH.

**Tar oil in Diesel engines.** H. MOORE. Diesel Engine Users' Assoc., May 26, 1918. Rep. 24 pp.; *J. Soc. Chem. Ind.* 37, 572A(1918).—Almost all heavy tar distillates are suitable for use in Diesel engines. Although the gross heat value of tar oils of British origin averages about 10.2% less than that of petroleum oils, the increase in consumption is not higher by this amt. for the reasons that tar oil generally yields a higher thermal efficiency than petroleum oil (probably due to its lower viscosity), and owing to the av. H content of tar oil being only about 6.9% as against about 11.5% for petroleum oils. The av. ignition point for tar oils is about  $480^\circ$  as against  $260^\circ$  for petroleum oils and it is this difference which is responsible for obtaining ignition of tar oils. With a normal tar oil, petroleum is necessary for starting with compression under 670 lbs. per sq. in., but good running is obtained at over  $\frac{3}{4}$  load with a compression of 460 lbs. per sq. in. Shale oil is particularly serviceable as an ignition oil with pilot ignition gear on account of its low ignition point. High temps. of the circulating water help the combustion of tar-oil to a small extent. Heating the cycle air lessens the output of the engine by rarefying the air, but aids the combustion of tar oils. Advancing the fuel valve is a distinct advantage. Mixing oils is of doubtful advantage, as it is necessary to employ more than half petroleum to obtain moderately good results. Hot blast is by far the most helpful modification for burning tar oil, but is rather dangerous, as it might cause explosions in the fuel-valve casing. The fuel-valve face suffers a little more with hot blast than in normal practice. Heating the fuel is useful from the point of view of increasing efficiency by reducing viscosity and as a means of dissolving naphthalene. Improved running on tar oil at low loads is obtained by restricting the flame plate but this is only at the expense of full load results. Wear on exhaust valve is not very serious with tar oils, but is a much more important matter when burning raw tars. It only becomes serious when firing is uncertain, and is generally much worse when running on tar oil alone than with the pilot ignition system. Oils which gave

an abrasive ash on ignition may cause trouble even when this amounts to less than 0.08%, but when the ash consists largely of  $\text{Na}_2\text{SO}_4$ , much higher ash contents are permissible. Tar oils containing pitch cause many troubles, but it is almost entirely free C which affects the use of such mixts. in Diesel Engines. J. H. YOUNG.

**Tar as fuel oil for Diesel engines.** O. SCHERTEL. *J. Gasbel.* 61, 493-5(1918); *J. Soc. Chem. Ind.* 38, 4A(1919).—Heated filtered tar has been used with complete success for 3 years as fuel for two 100-h. p. Diesel engines worked alternately. Paraffin oil, when available, was used as ignition oil but occasionally tar was used alone. Gas oils and heavy petroleum were also used to replace paraffin oil as an ignition fuel. It was then found to be advantageous to run on tar-oil for 5 or 10 min. at starting, a procedure unnecessary with paraffin oil. The calorific value of the tar was about 8700 cal., and 337 g. of tar with 20 g. of ignition oil were required to produce 1 h. p. hr. The cost of running with the usual oil would have been  $2\frac{1}{3}$  times as great. The cylinders and piston rings remained bright and clean throughout. The crude tar was run into large storage tanks where it was kept heated by hot-water pipes, and where water and solid matter sepd. It was then pumped up to a higher level into a tank holding sufficient for one day's requirements (about 500 kg.). Here also the tar was kept heated and a further sepn. of water took place. Thence the tar ran by gravity through 2 gravel filters, the grain size of the first filter being 3 to 5 mm. and in the second 1 to 2 mm., and from these through a meter and regulator to a heater where the temp. was raised to about 60°. This temp. was found necessary in order to insure complete combustion of the tar. Two pairs of filters were used alternately in periods of about 3 weeks. A steady flow of tar through the filters was obtained by fitting to the outlet of the fine filter an open vertical pipe in which the filtered tar ascended when the feed to the engine was interrupted by the regulator. The tar and the heating water were heated by means of the exhaust gases from the engine. J. H. YOUNG.

**Briquetting of coke breeze.** KAYSER. *J. Gasbel.* 61, 541-7, 556-8(1918); *J. Soc. Chem. Ind.* 38, 34-5A.—Coke breeze requires 9-10% of pitch as binding material for briquetting purposes. In the patented "Koxit" process part of the pitch is replaced by a cheaper fluid binding material consisting of oil-gas tar and vertical retort tar in about equal parts. The mixt. of coke, pitch, and liquid binding medium is heated with superheated steam and pressed into egg-shaped briquets. In a series of trials, the moisture content of the coke breeze varied from 9.3 to 19.9%. The softening point of the pitch was 83°. A very satisfactory briquet was obtained by the addition of about 5% pitch and from 0.8 to 1% of the liquid binding material. The air-dried briquets contd. 3.5-4.5% of water and yielded about 14-16% ash. The calorific value was 6400-6600 cal. The quantity of water taken up when the briquets were stored under water for 7-8 days ranged from 13 to 18.6%, as compared with 11.9% by brown coal briquets under similar conditions. The loss of wt. after transport by rail, unloading, and storing for 6 months was in 3 tests with large quantities (3200, 3250 and 7200 kg.) 4.1, 6.3, and 4.3%, resp. For preference the pitch should have a softening point between 60° and 75°. For steam-raising purposes, an addition of from 20 to 25% of coal dust is in general necessary to secure efficient combustion. The briquets do not crumble when burnt; this is due to the coking of the fluid binding material during the combustion. This coking effect is increased by the use of liquid binding materials capable of acting as solvents for the pitch, and, of such materials, vertical retort and chamber oven tars and oils, as anthracene oil, are found particularly suitable. Very viscous binding material is not suitable, as by its use air is entrapped in the pores of the coke breeze and the briquet on subsequent combustion crumbles owing to the expansion of the entrapped air. A process has been patented whereby this effect is reduced by adding the liquid binding material under reduced atm. pressure. The total

cost of manuf. including establishment charges, cost of material and labor, since the commencement of the war has amtd. to \$1.83 per ton. The sale price, detd. by the relative calorific values of the resp. fuels, is about 14 to 15% lower than that of coke.

**Ammonium sulfate.** J. BECKER. U. S. 1,291,729, Jan. 21. Ammoniacal gas from by-product ovens or gas works is passed through a cooler, condenser and tar-separator and the ammoniacal liquor thus obtained is led to an ammonia still and the  $\text{NH}_3$  from the still is led to a saturator to produce  $(\text{NH}_4)_2\text{SO}_4$ . The satn. bath is a satd. soln. of  $(\text{NH}_4)_2\text{SO}_4$  containing 5% of free  $\text{H}_2\text{SO}_4$ .  $\text{H}_2\text{SO}_4$  is added to the bath as required to replace that consumed by neutralization with  $\text{NH}_3$ . The temp. of the bath is raised by heating coils to evap.  $\text{H}_2\text{O}$  and facilitate pptn. of  $(\text{NH}_4)_2\text{SO}_4$  produced. The heat thus used is supplied by the distillate gases and vapors from the  $\text{NH}_3$  still.

**Ammonium sulfate.** J. BECKER. U. S. 1,291,730, Jan. 21. Ammoniacal liquor from by-product coke or gas ovens is freed from tar and distd. The still vapors are dephlegmated and reheated and a portion of the cooled tar-freed gas is passed into the distn. current to augment the vol. of the still vapors and derive heat with them in the distn. and reheating operation. The commingled gases and vapors thus produced and superheated are passed into the current of the other portion of the tar-freed gas to superheat the latter and the resulting superheated mixt. of gases and vapors is passed into a satn. app. to produce  $(\text{NH}_4)_2\text{SO}_4$ .

F. M. ROGERS.

**Estimation of benzene and toluene in petroleum.** F. B. THOLE. *J. Soc. Chem. Ind.* 38, 49-43T(1919).—The procedure adopted by most chemists for the estn. of benzene and toluene in petroleum consists in preparing a petrol boiling up to about  $160^\circ$  and so containing all the benzene and toluene in the oil. This is subsequently distd. through a good fractionating column, fractions being collected between certain temp. limits and assumed to contain, resp., all the benzene, toluene, etc. These fractions are then assayed by treating with nitro-sulfuric acid, fuming  $\text{H}_2\text{SO}_4$ , liquid  $\text{SO}_2$  or  $\text{Me}_2\text{SO}_4$ , reagents which absorb the aromatic hydrocarbons by chem. action or by selective soln., and measurement of the vol. of aromatic compd. thus absorbed. Each of these operations is liable to a number of errors, is largely influenced by the personal factor, and involves assumptions of very doubtful validity. The proposed method consists in treating the prepared sample containing the benzene and toluene with 3 times its vol. of 98%  $\text{H}_2\text{SO}_4$  over a period of 30 min. during which time the sample is shaken at frequent intervals. Instead of measuring directly the vol. of the supernatant layer of unattacked hydrocarbon, as has been done, a sp. gr. detn. is made of the initial fraction

and of the residual spirit after acid treatment. Knowing the sp. gr. of the aromatic component the percentages present may be calcd. from the formula: % aromatic =  $\frac{[(\text{initial sp. gr.} - \text{final sp. gr.}) / (\text{sp. gr. of aromatic} - \text{final sp. gr.})] \times 100}{1}$ . The expression for % aromatic is based on the assumption that the sp. gr.-compn. curve for mixts. of aromatic and non-aromatic hydrocarbons is a straight line, which is not the case, the sp. gr. being slightly less than the calcd. according to the law of mixts. It is possible, however, to correct for the deviation by the construction and use of a "deviation curve." The presence of small quantities of olefins and S compds. in the petroleum has little effect on the accuracy of the method.

J. H. YOUNG.

**Testing illuminating oils.** J. F. NEWTON AND F. N. WILLIAMS. *Petroleum Age* 6, 81-84 (1919).—A description of the following tests is undertaken, gr., flash, fire, viscosity, chill, S, color, ash, burning, doctor, odor, foreign matter, calorific value and distn. The burning and S tests are most important as these det. the value of the oil both for lamps and stoves. The Saybolt colorimeter and kerosene viscometer are described and the use of the latter is shown in detail.

R. R. MATTHEWS.

**Examination of drilling oils and their substitutes.** J. MARCUSSEN. *Mitt. Kgl. Materialprüfungsamt.* 36, 107-12 (1918); *J. Soc. Chem. Ind.* 37, 725-6A (1918).—Owing to a shortage of so-called water-sol. oils used in the drilling of armor plate, Germany used a great many substitutes. Those which are free from oil include sulfite lyes, exts. of vegetable mucilage, and solns. of glue and are characterized by dissolving in water without forming an emulsion. When used as a substitute for drilling oils, the sulfite lyes require the addition of alkali as a rust-preventive. The brown specks formed on the metal when strongly alk. sulfite lyes are used are due to tannin constituents of the lyes. Sulfite lyes when treated with an excess of dil. HCl yield a ppt. of ligninsulfonic acid, which is insol. in ether or benzene, and is decompd. by strong HCl, with the liberation of SO<sub>2</sub>. They reduce Fehling soln. and solns. of dyes such as methylene blue, and give the naphthol-sulfuric acid reaction for carbohydrates. On evapn. sulfite lyes leave about 10% residue containing 10 to 15% ash, 1 to 10% S and about 0.4% N. Vegetable mucilage exts. are prepd. from seeds such as linseed, and especially from carrageen moss, which is first soaked and then boiled with water. Good preps. should give a nearly fluid jelly with 16 to 20 parts of H<sub>2</sub>O. They are characterized by the presence of vegetable particles which are rendered more distinct by staining with I. They yield a ppt. with alc. which does not dissolve readily in hot water. Fehling soln. is not reduced, unless the liquid has previously been heated with dil. acid. Glue solns. for drilling purposes are prepd. by dissolving 40 parts of glue in 50 parts of H<sub>2</sub>O and 10 parts KOH soln. (50° Bé., sp. gr. 1.53). The other group of drilling oil substitutes consists of mixts. of the above mentioned preps. with mineral oil or tar oil, as, for example, a mixt. of 80 parts of sulfite lye, 5 parts KOH soln. of the above mentioned strength, and 15 parts of tar oil or mineral oil. The methods for the analysis of these mixts. are given.

J. H. YOUNG.

**Oily constituents of acid tars from petroleum refining.** S. GASIOROWSKI AND G. VON KOZICKI. *Bergbau u. Hütte* 4, 181-2 (1918); *Z. angew. Chem.* 31, II, 354; *J. Soc. Chem. Ind.* 38, 35A.—An oil of d<sub>4</sub> 0.9685, setting pt. —19°, flash point (Martens-Pensky) 86° and viscosity (Engler) 2.2° at 20° has been obtained by steam distn. of the acid tar produced by dilg. with water the waste acid of petroleum refining. The oil was completely sol. in liquid SO<sub>2</sub>, a proof that the chief function of the H<sub>2</sub>SO<sub>4</sub> in petroleum refining is to remove unsatd. compds. Different fractions of the oil sep'd. by vacuum distn. showed no variation in sp. gr. No nitro deriv. could be prepd. from the distillate obtained by destructive distn. of the oil, showing that further unsatd. compds. are formed during the decompn.

E. J. C.

**Heat of fusion of paraffin wax.** G. VON KOZICKI AND S. VON PILAT. *Chem. Umschau* 1917, 71; *Chem. Ztg.* 42, 147(1918); *J. Soc. Chem. Ind.* 37, 681A.—The heat of fusion of paraffin wax was detd. by the lowering of the solidifying point on adding a compd. (naphthalene, dimethylaniline, phenanthraquinone) of known mol. wt. It was found that the latent heat of fusion ranges from 38.9 to 43.9, increasing with rise of sp. gr., solidifying point, and mol. wt. E. J. C.

**Scientific gages.** B. C. RINEHART. *Petroleum Age* 6, 98(1919).—An illustration of app. is shown for gaging oil tanks. It consists of a liquid level recording gage with a recording thermometer. Readings with a gage pole showing U. S. gals. should be made once a day. The app. is specially applicable to the light oils and shows a continuous record of the tank for a day or for a week depending on the recording chart used. R. R. MATTHEWS.

**Greenstreet cracking plant.** R. H. KINNEAR. *Petroleum Age* 6, 76-8(1919).—This process depends on the mixt. of live steam with oil just before the cracking coils are entered. When the conditions of speed, pressure and steam are correctly regulated there is no C formed in the coils. The cracking coils are of 2-in. tubing and have a length of 425 ft. From the cracking coils the vapors enter an expansion tank and from there pass into condensers. 50 to 60% conversion to gasoline is claimed at a manufacturing cost of 1 to 2 cents per gal., depending on local conditions. R. R. MATTHEWS.

**Valuation of natural and artificial bitumens for insulating cables by means of a new "bitumen tester."** DUPRÉ. *Chem. Ztg.* 42, 445-6(1918); *J. Soc. Chem. Ind.* 37, 645A.—Attempts were made in Germany to produce substitutes for elaterite which is used as an insulating material for elec. cables. "Insulation masses" were made by incorporating 40% or more of kaolin, chalk, etc., with natural or artificial bitumens having a dropping-point (m. p.) of about 40-60°. Such addition, however, only retards the flowing of the mass at higher temps., and cables insulated with such materials lose their shape as certainly, though not as soon, as if the unfilled bitumen were used. The improvement of ordinary bitumens, asphalts, pitches, etc., so as to raise the dropping point, while retaining their elasticity and ductility, can only be effected by a deep-seated chem. alteration of the bitumens. For example, if the mineral matter is made to combine with the bitumen as in Schon & Co.'s patent process (not yet published) the dropping point of the bitumen may be raised from 41° to 115°. J. H. YOUNG.

**Acetone.** H. P. BASSETT. *Chem. Met. Eng.* 20, 190(1919).—By heating a mixt. of lime and sawdust or wood in a similar state, a yield of 26% of acetone and higher ketones can be obtained. The mixt. should not be heated too rapidly, allowing about 10 hrs. to reach the max. temp., and removing the vapors as quickly as possible by means of steam or an inert gas such as CO<sub>2</sub>. Sulfite waste liquors also can be dried and then treated with lime to produce acetone and higher ketones. O. E. BRANSKY.

**Determination of turpentine and the detection of adulterants (TAUSZ) 26. Apparatus for the extraction of liquids in towers filled with Raschig's rings (RASCHIG) 1. Device for determining the dropping point of fats, waxes, bitumens, etc. (DUPRÉ) 1. The limits of separation by fractional distillation (DUPTRON) 1. Oilology (PETERSON) 8. Compact oil-testing cup (ANON.) 4. The testing of switch and transformer oils (SCHNEDELL) 4. Electrostatic precipitation (BRALEY) 4.**

**Horizontal pressure still for treating petroleum oils.** H. B. SETZLER. U. S. 1,292,966, Jan. 28.

**Petroleum-distillation apparatus.** G. A. HUMASON. U. S. 1,291,899, Jan. 21.

## 23. CELLULOSE AND PAPER.

A. D. LITTLE.

**The American aspen cellulose.** VICTOR LITZHAUER. *Centr. für oesterr. Papier Industrie* 23,(1918); *Paper* 23, No. 23, 646-52(1919).—A contribution to the microscopy of American aspen cellulose, together with a discussion of the com. yield of pulp from poplar pulp wood. R. B. ROE.

**Making cellulose from cotton linters.** JOSEPH H. WALLACE. *Paper* 23, No. 23, 634-42(1919).—A description of the methods of cotton purification at the Government explosive plant, Nitro, W. Va. R. B. ROE.

**Scheme for the analytical investigation of vegetable fibrous materials and the cellulose prepared from them.** C. G. SCHWALBE. *Verein deut. Chem.*, Sept., 1918; *Z. angew. Chem.* 31, 193-4(1918); *J. Soc. Chem. Ind.* 37, 685-6A.—The time is ripe for a coördinated reinvestigation on a uniform basis of all the standard raw materials of the textile and cellulose industries, in order that the proximate compn. of these can be definitely fixed, the variations due to environment, etc., defined, and the results utilized for the classification and evaluation of new or little known materials. S. discusses the question of the selection of the analytical "consts." of most general significance and of the standardization of methods and app. These questions should be settled by a committee of recognized standing, and data should be accumulated on the agreed basis. The scheme of analysis proposed by Cross and Bevan and utilized by other investigators is regarded as not fully adapted to the light of modern knowledge; it is considered to be unnecessarily long and to contain factors of undetd. significance. The abbreviated scheme recommended by S. comprizes detns. of ash, moisture, fat, wax and resin, cellulose, furfural, methylfurfural, and methoxyl. The pentosans are satisfactorily represented by the furfural value, but certain standardization of methods and app. is required to ensure concordant results. The lignin may be taken to be represented by the methoxyl value, but it is possible that this requires correction by the results found for methylfurfural which is supposed to represent methylpentosans. E. J. C.

**Tearing resistance of paper.** SIDNEY D. WELLS. *Paper* 23, No. 23, 750-3(1919).—An investigation of the tearing strength of different samples of paper was made in which the instrument used consisted of the Schopper tensile tester slightly modified for the purpose. The results obtained indicate that the tearing test furnishes valuable data from which to judge the strength of a paper. While the Schopper tensile tester may be used satisfactorily, a smaller, cheaper and better instrument for the purpose should be devised. R. B. ROE.

**Requirements of a good cooking acid.** W. E. BYRON BAKER. *Paper* 23, No. 23, 764-78(1919).—A full description of the methods of analysis of the cooking acid used in the prepn. of sulfite pulp. Various sources of error are pointed out, and there is a discussion of the methods of standardization of the volumetric solns. used. R. B. ROE.

**Alcohol from waste sulfite liquor.** VERNON K. KRIEBLE. *Paper* 23, No. 23, 753-62(1919).—An analysis of 12 representative Canadian sulfite liquors showed that the best samples contained as much sugar as European liquors and should yield at least 1% by vol. of EtOH. A description of the analytical methods used is given. The liquors examd. fall into two classes, in which 28 and 20% resp., of the org. matter is in the form of reducible sugars. The difference is not due to the relative proportions of spruce or balsam, to the strength of the cooking, nor to incomplete hydrolysis of the polysaccharides, but to the destruction of sugar in the cook. The exptl. results further showed that (1) the amt. of sugar does not reach a max.; (2) most of the sugar is produced before the end of the 7th hr.; (3) the temp. after the 7th hr. is most important;

the yield being materially reduced if the temp. exceeds  $145^{\circ}$ ; (4) the fermentable sugars are the first to be destroyed.

R. B. ROE.

Acetone (BASSETT) 22. Making money from bagasse (BAUNARD) 28.

---

**Moldable pyroxylin composition from wet pyroxylin.** W. G. LINDSAY. U. S. 1,292,819, Jan. 28. Wet pyroxylin is combined with benzyl benzoate,  $H_2O$  is removed by bibulous pads or otherwise and the mixt. thus prepd. is then suitable for working up with solvent liquids and modifying agents such as are ordinarily used with pyroxylin and camphor. The pyroxylin has a selective action in retaining the benzyl benzoate, during the removal of the  $H_2O$  by expression or absorption.

**"Carbon-paper."** S. HATTORI. U. S. 1,292,404, Jan. 21. Coating material for prepg. "carbon paper" is formed of a Ba soap mixed with oil and pigment, *e. g.*, Ba stearate 3 kg., castor oil 2.25 kg. and violet lake 3.25 kg. Soaps of Al or Mg also may be used.

---

## 24. EXPLOSIVES AND EXPLOSIONS.

---

C. E. MUNROE.

**Explosives.** ROBERT L. LEWIS. *Mining Sci. Press* 118, 245-53(1919).—A condensed, well illustrated, description of commonly known explosives. The trade names of different dynamites do not truly represent their comparative strengths. A 60% straight dynamite and a 60% low-freezing dynamite will not have the same strength. The potential energy of 40% ammonia dynamite and 40% gelatin dynamite is greater than that of 40% straight dynamite, but the useful work that can be done, represented by the propulsive and disruptive effects, is less. The strength of 60% low-freezing dynamite is not quite equal to that of 40% straight dynamite. CHARLES E. MUNROE.

**Report Chief Bureau of Ordnance, U. S. N. for 1918.** RALPH EARLE.—An account is given of the ammunition on the J. L. Luckerback, which was thoroughly wet by the flooding of her magazines when a fire broke out on the ship and which functioned satisfactorily in the subsequent engagement of this vessel with a German submarine, 202 rounds being fired. Some two pages are devoted to accidents in manuf. in this country, with the exception of a review of the Halifax disaster, following a collision of the Mont Blanc with the Imo, wherein it is stated "The former's benzine tanks were soon ruptured and the benzine caught fire from the boilers, the ship being soon enveloped in flames. The explosives detonated in 17 minutes after the fire started, a time all experiments indicate as necessary to detonate T. N. T., 'D,' or picric acid after a fire is kindled about it." Cf. C. A. 12, 426.

CHARLES E. MUNROE.

**Costs and efficiencies for Government explosives factories.** K. B. QUINAN. *Chem. Trade J.* 64, 115-7, 139, 161-2(1919).—This is an extended résumé of two reports of the British Ministry of Munitions, Dept. of Explosives Supply, giving detailed data for the operations, during January-June 1918, attending the manuf. of T. N. T., nitrocellulose, nitroglycerin, cordite, picric acid, tetryl,  $NH_4NO_3$ ,  $NH_4ClO_4$ ,  $Ca(NO_3)_2 \cdot 4H_2O$ ,  $Et_2O$ ,  $HNO_3$ ,  $SO_3$ , and the denitration, distn. and concn. of spent acids. In the majority of instances the data for a topic are presented in tabular form, showing for each factory producing this material, the total product, the efficiency, the quantity and cost of each of the materials used, the cost of "services," (including maintenance, labor and general expenses), and the cost per unit of the product. In the case of T. N. T. 6 factories are thus compared with one another; in the case of  $HNO_3$ , 9 factories;  $SO_3$ , 8; denitration, 10; concn 12; and a fewer number in the other tables. In these

tables are compared the results from different methods of operation as in the  $\text{SO}_2$  table giving those from the Grillo, Mannheim and Tentelew processes; in the concn. table, giving those from the Cascade, Gaillard and Kessler systems; in the  $\text{NH}_4\text{NO}_3$  table, giving those from the ammonia-soda process, the  $\text{Ca}(\text{NO}_3)_2$  conversion process, the  $\text{NaNO}_3$  conversion process; and so on. The system of gathering the statistics from which these are taken was introduced as a means of controlling the operations of the many new factories which were erected and operated to meet the extraordinary demands of war and which were necessarily entrusted largely to inexperienced staffs and personnel. Each of the tables is explained and analyzed and though in instances the av. cost of maintenance steadily increased the general improvement shown justifies the use of this system of control.

CHARLES E. MUNROE.

**Report Chief Inspector Bureau of Explosives A. R. A. for 1918.** COL. B. W. DUNN. B. E. *Rept.* No. 12, Feb. 1919.—Our military program, adopted early in 1918, called for a production in one year of about two billion lbs. of explosives for military use, and for the production of poisonous liquids and gases at a max. rate of about 200 tons per day. The actual production attained under this program cannot be stated at this time, but it is known that for most of the year preceding the signing of the armistice, the monthly production of military explosives exceeded eighty million lbs., or more than 2000 carloads of 40,000 pounds each per day. These explosives moved to the loading plants where each carload of explosives produced not less than 5 carloads of explosive projectiles. A conservative estimate shows that the railroads of the U. S. during the busy months of 1918, had at all times not less than 50,000 cars in transit on Government business and bearing the explosive placard. This was in addition to the av. of 5000 cars in transit to meet the normal commercial demand, and does not include the cars bearing military explosives to Canada. In meeting this abnormal demand only 11 accidents of all kinds occurred in the transportation of explosives during 1918, only four persons were injured, and only 1 life was lost; and the total property loss was only \$33,238. Of these results the only one chargeable to war material was the loss of one life, which occurred in Canada. This excellent record is due, primarily, to the general use of standard packages and of standard methods in loading, blocking and bracing the packages in cars. Such standardization is secured more readily for explosives than for many of the other classes of dangerous articles on account of the relatively small number of shippers of explosives, and their very general appreciation of the necessity for strict compliance with the regulations. The report is accompanied by seven appendices: (1) containing statistical tables covering reported explosions, fires, and accidents in the transportation or storage on railway property awaiting delivery of explosives and other dangerous articles; (2) report from the Chemical Laboratory; (3) recommendations for the proper handling of wrecks involving tank cars of inflammable oils; (4) instructions for packing  $\text{HNO}_3$  for transportation; with methods for testing carboys; and (6) containing detailed descriptions of the more important instances of accidents. Cf. C. A. 12, 2441.

CHARLES E. MUNROE.

**The construction of graphs for calculating the revivification of spent acids.** R. A. FOWLER. *J. Soc. Chem. Ind.* 38, 34-67(1919).—In order to lessen the work of calcg. the amts. of fortifying and sulfuric acids to be added to a spent acid to give a mixed acid of desired compn. F. has devised a graphical chart from which these figures can be readily detd. Details are given both as to the construction of the chart and as to the mathematical calcns. involved in its detn. It is claimed that results can be obtained from the graph to within 0.02% in the nitrating acid.

ISMAR GINSBERG.

**Solvents for nitrocellulose.** ANDRÉ DUBOSC. *Caoutchouc & gutta-percha* 16, 9716(1919).—A practically complete list.

JOHN B. TUTTLE.

**Rupture of cast iron in contact with mixed acid.** A. C. CUMMING. *J. Soc. Chem.*

*Ind.* 38, 31-27(1919).—This article is a very interesting report on an explosion of two cast-iron eggs, in the course of blowing T. N. T. mixed acid, under a pressure of 60 lbs. per sq. in. Examn. of fragments of the eggs showed very slight corrosion of the metal. Photomicrographs indicated that the acid had penetrated the metal to  $\frac{1}{2}$  of its thickness ( $1''$  to  $1\frac{1}{2}''$ ) and had formed small clusters of Fe salt crystals. The explosion is attributed to the expansive force caused by the growth of these crystals. Reference is made to similar failures of cast-iron app. used with oleum, which in this case are due to the generation of gases within the iron walls, caused by the decompn. of the  $H_2SO_4$  by the reducing action of the Fe. It is advised that no cast iron be used in the construction of app. coming in contact with oleum or  $HNO_3$ , whether pressure is employed or not.

## 25. DYES AND TEXTILE CHEMISTRY.

L. A. OLNEY.

Microscopical analysis of textiles. F. PUGH. *Can. Chem. J.* 3, 84-6(1919).—An interesting popular address which gives descriptions of the microscopical appearances of various animal and vegetable fibers used for textiles.

L. W. RIGGS.

Making wool-like fibers from bast. PLANTE FEBURE. *Ind. Merc.* 41, 163-4 (1918); *Chem. Weekblad* 16, 80-1(1919).—Bast fibers can be bleached and made fine and woolly in 1 process by treating with an oxidizing agent in a strongly alk. bath, usually at room temp. Sometimes it is better to warm to  $40^\circ$ . Sometimes a second treatment in the same bath, with addition of soap or Turkey-red oil, is necessary to obtain the desired softness. Mixed with wool, the fabrics woven from this material show no difference in appearance or feel from pure wool fabrics. Dyeing causes no ill effects.

JULIAN F. SMITH.

Some problems relating to the scouring process. S. A. SHORTER. *J. Soc. Dyers Colourists* 35, 55-8(1919); cf. *C. A.* 12, 2447.—Three problems are considered: (1) best concn. of soap in scouring; (2) best concn. of alkali and (3) why a soap bath becomes exhausted. (1) Soap acts as a detergent because it lowers enormously the tension of the interface between water and grease, thus assisting in wetting out, and because as a colloid it exerts a stabilizing effect upon emulsions and suspensions. A curve showing the relation between "drop-number" and the concns. of soap soln. indicates that so far as surface tension is concerned it is a waste of soap to use it at a concn. much greater than 0.4%. Expts. on the effect of a soap on the stability of fine suspensions have shown that there is a max. effect at concn. from 0.2 to 0.3%, and from a study of both effects it is concluded that 0.46 represents the max. concn. at which it is desirable to use soap for scouring. The presence of alkali increases enormously the surface tension; the alkali, if its concn. exceeds a comparatively small amt., tends to diminish the stabilizing effect so that in actual practice one must compromise with these two effects. This usually results in sacrifice of stabilizing effect for the sake of effecting rapid initial emulsification.

(2) When pieces are scoured with alkali alone the emulsification is due to the formation, in the surface layers sepg. the soln. and the oil on the piece, of a layer of soap by the interaction of the alkali and the free fatty acid in the oil. The stabilization of the emulsion is due to the passing into soln. of the soap thus formed. Surface tension effect of alkali against an oil containing free fatty acid is exhibited by extremely weak solns. of alkali. Such weak solns. have no stabilizing power. Alkali must be sufficient to form a soap soln., that is strong enough, but if too concd., a soap soln. cannot be formed, and the emulsion droplets are coagulated. This coagulating effect seems to occur between concns. of 1 and 2%. In scouring with alkali alone it is better to avoid high concns. in the initial stages, *i. e.*, until enough soap has been formed and dissolved to produce the necessary stabilizing effect. (3) Exhaustion of a soap soln. may be due to 2 causes (a) removal of soap from soln.; (b) excess of dirt and grease in soln. The emulsion droplets are coated with a soap layer and if the droplets are sufficiently fine an appreciable amt. of soap may be removed in this way. In case of wool scouring liquors, the main cause of their ceasing to scour is their fouling with dirt and grease.

L. A. OLNEY.

**Sizing.** R. H. PICKARD. *J. Text. Inst.* 10, 54-5(1919); cf. *C. A.* 12, 1125, 1514.—But little accurate work has been done upon the subject of sizing of textiles, partly because the relative cost of the size to the cost of the cloth was small, and partly because many people fancied they possessed valuable secrets with reference to the details of the process. Generally the substances used were chosen because of the feel imparted to the cloth. The feel depends upon the starches and the softeners (fats) employed. The production of fats of almost any degree of hardness or of m.p. has opened a wide field to the size mixer as it is possible to produce cloth of any desired feel by varying the fat used. Sizing should also be studied with reference to the behavior of the warp under the strain of weaving, the effect on strength and elasticity being considered as well as pliability. At present too much is left to judgment. The coöperation of "practical and scientific" men is urged.

L. W. RIGGS.

**Silk weighting with zirconium sulfate.** E. RISTENPART. *Färber-Ztg.* 29, 26 (1918); *J. Soc. Chem. Ind.* 37, 687A.—Expts. show that the weighting of silk by Zr sulfate cannot replace the weighting by Sn salts.

E. J. C.

**Differentiation of natural and artificial silks.** A. HERZOG. *Kunststoffe* 7, 277-8 (1917); *Z. angew. Chem.* 31, II, 225(1918); *J. Soc. Chem. Ind.* 37, 574A.—A physical method of differentiation is described which is based on the differences between the refractive indices and which is applicable in the case of dyed fibers. A fiber of natural silk mounted in aniline and examd. under a microscope with a Nicol prism is almost invisible when its longitudinal axis is at right angles to the plane of polarization of the prism, and becomes more and more visible when the stage is rotated, until it reaches a max. of visibility at right angles to the original position. Artificial silk fibers have a  $n$  considerably below that of aniline and are distinctly visible at all positions of the revolving stage.

E. J. C.

**Oxygen tendering of laundry (textile) goods.** P. HEERMANN. *Chem. Ztg.* 42, 337-8, 342-3(1918); *J. Soc. Chem. Ind.* 37, 576A.—H. replies to various objections which have been raised against his previous work (*C. A.* 12, 1254) and brings forward evidence to show that washing powders contg. available O or bleaching agents are more injurious to fabrics than are those free from these substances. In practice, it is quite possible to have conditions under which the bleaching powders will produce local destruction and perforation of fabrics.

E. H.

**Analysis and inspection of impermeable fabrics.** *Ind. chim. min. met.* 6, 14-5 (1919); *Ind. tessile e tintoria* 19, 54.—The following physical tests are of value: pre-

liminary examn. of the cloth to detect visible imperfections; detn. of time required for water under slight pressure to pass through; detn. of resistance to molds by inoculation with spores and incubation for several days; effects of changes of temp. between  $0^{\circ}$  and  $100^{\circ}$  and of action of light, especially ultraviolet. The impregnating material may be removed by soln., hydrolysis, etc., and its amt. and nature detd. by chem. tests. If any sterilizing substance has been used it should be examd. similarly.

J. S. LAIRD.

**Determination of loss of oxygen during the use of oxygen-yielding bleaching and washing materials.** A. GRÜN AND J. JUNGSMANN. *Chem. Ztg.* 42, 473-5 (1918); *J. Soc. Chem. Ind.* 37, 729A.—The method described consists in heating a known wt. of fabric with a definite quantity of the bleaching agent in a flask under reduced pressure. The flask is connected through a condenser with a gas buret, in which any gases given off during the heating are collected. Subsequent analysis of the gases given the quantity of O evolved from the bleaching agent and not combined with the fabric, etc. The quantity of N found in the gases is taken as a measure of the air present in the app. and an allowance is made for the O derived from this source. Results of expts. with perborates show that from 60 to 80% of the active O escapes in the gaseous form, but if soap is also present the loss is under 12%. The greater part of the active O is absorbed by the oxidizable constituents of the soap.

E. J. C.

**Dyeing of cotton fiber with basic dyes.** R. HALLER. *Kolloid-Z.* 23, 100-6 (1918); *J. Soc. Chem. Ind.* 37, 729A.—The mechanism of dyeing cotton with basic dyes is shown to be the following in the case of methylene blue. On immersing the fabric in a tannin soln., this by virtue of its highly disperse state penetrates into the interstices, and when the tannin-charged fabric is placed in a soln. of tartar emetic this substance as a mol. disperse soln. penetrates very rapidly and forms in the interstices an insol. Sb-tannin compd. When now the fabric is placed in the methylene blue bath this substance, being also highly disperse, penetrates and forms a complex lake, tannin-Sb-methylene blue, which is fixed in the fiber. A similar course is followed when  $Al_2(SO_4)_3$  is used instead of tartar emetic, but in this case the tannin-Al compd. is sol. and consequently the colors are not so fast as in the former case.

E. J. C.

**Mordant dyes in calico printing.** H. POMERANZ. *Monatsschr. Text.-Ind.* 33, 30-1, 38, 45-6 (1918); *Z. angew. Chem.* 31, II, 350; *J. Soc. Chem. Ind.* 38, 39A.—The manner is discussed of the fixation of acid mordant dyes in calico-printing, particularly of alizarin. The formation of the color-lake on the fiber under the action of steaming is the result of a mutual reaction between the fiber, mordant, and dye, leading to the production of a colloidal coloring matter, which in itself has the property of dyeing the fiber but which does so still better through the part played in its formation by the colloidal alumina deposited in the fiber. According to Liebermann's expts. (cf. *C.* A. 2, 2811) no stoichiometrical relations exist between dye and mordant. The oil exists both as a constituent of the color-lake and in a peculiar form of direct combination with the cotton. Before the appearance of Turkey-red oil, P. employed oil in the printing color for goods not prepd. with oil. He used ricinoleic acid emulsified with saponin and the color was thickened with starch and gum, the starch being gelatinized by heating together with the oil and gum. The portion of the oil mordant intended to enter into combination with the color-lake was added to the printing color in the form of Ca ricinoleate.

E. J. C.

Scheme for the analytical investigation of vegetable fibrous materials, etc. (SCHWALBE) 23. Recovery of volatile inflammable solvents in industrial operations (SESTINI) 18. Making cellulose from cotton linters (WALLACE) 23.

**Statistics of Synthetic Dyestuffs Imported into the United Kingdom during the Year 1913.** Report of the Commissioner for Dyes, Board of Trade. H. M. Stationery Office. 168 pp.

**Copper compounds of *o*-hydroxyazo dyes.** E. ANDERWERT, H. FRITZSCHE and H. SCHOBEL. U. S. 1,292,385, Jan. 21. Cu compds. are formed of azo dyes derived from *o*-NH<sub>2</sub> compds. as one component, *e. g.*, dyes from *o*-NH<sub>2</sub>C<sub>6</sub>H<sub>4</sub>OH, 2,4-NH<sub>2</sub>(NO<sub>2</sub>)<sub>2</sub>-C<sub>6</sub>H<sub>3</sub>OH, or chloronitroaminophenols, coupled with naphtholsulfonic acid derivs. (forming either mono- or poly-azo dyes), by reacting on the dye in acid soln. with CuSO<sub>4</sub>. The Cu compds. dye like the other substantive dyestuffs from their aq. solns. and yield colors which are more fast to washing and especially to alkalis and acids than the original dyes uncombined with Cu. The fastness to light is also improved by conversion of the dyes into Cu compds. The pat. gives many examples of dyes prepd. by this method.

**Fixing dyes on fabrics.** A. A. GEHRLEIN. U. S. 1,292,453, Jan. 28. NaHSO<sub>3</sub> is used as a fixing agent on fabrics which have been previously treated with a dye. A faster and brighter color may be obtained than by the use of alum.

**Artificial threads from viscose.** G. WALTHER. U. S. 1,292,544, Jan. 28. Pptg. baths for the manuf. of threads from viscose are prepd. with aldehyde-bisulfites or aldehyde sulfoxalates. Pptg. solns. may be formed of glucose 300 and 35-36° Bé. NaHSO<sub>3</sub> soln. 1000 parts; or 40% CH<sub>2</sub>O soln. 300 and 36° Bé. NaHSO<sub>3</sub> soln. 1000 parts; or acetone 186 and 36° Bé. NaHSO<sub>3</sub> soln. 1000 parts; or benzaldehyde 377 and 36° Bé. NaHSO<sub>3</sub> soln. 1000 parts or "rongalite" 400 and H<sub>2</sub>O 1000 parts; or phenol 94, Na<sub>2</sub>SO<sub>3</sub> 250, 40% CH<sub>2</sub>O soln. 76 and H<sub>2</sub>O 500 parts. These solns. are heated to about 50-60° during spinning and are adapted for use with viscose in various stages of the maturing operation. Na<sub>2</sub>SO<sub>4</sub> or NaOAc or sugars may be added to the baths. The baths remain clear during use so that irregularities in the spinning can be readily observed.

## 26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN.

**The analysis of red lead.** W. F. EDWARDS. *Chem. Met. Eng.* 20, 260(1919).—Compares the H<sub>2</sub>O<sub>2</sub>-KMnO<sub>4</sub> method for Pb<sub>2</sub>O<sub>3</sub> given in C. A. 10, 1019 with his I method (C. A. 13, 382). Hot water or diln. is not required and a regular 0.1 N KMnO<sub>4</sub> soln. with a factor of 0.03428 for Pb<sub>2</sub>O<sub>3</sub> is used. Results are given of samples run by the two methods, and although the results by the H<sub>2</sub>O<sub>2</sub> method are slightly lower, both methods check very closely.

J. E. CLARK.

**Safflower oil as a drying oil.** HAROLD H. MANN AND N. V. KANITKAR. *J. Soc. Chem. Ind.* 38, 36-38 T(1919).—Safflower seed grows in the driest areas of Deccan in western India, and contains an av. of 32% oil in the whole seed or 52% in the kernel. The oil is used almost exclusively for edible purposes. Analyses on 4 different samples showed *d*<sub>4</sub> 0.914; sapon. no. 177 to 203; acid no. 0.6 to 2.6; I no. 111 to 122; butyrefractometer at 40°, 63 to 64°. Satd. fatty acids consist mostly of palmitic acid. In order to test the statement of Lewkowitsch that the thickening of the oil on heating is due primarily to polymerization instead of to oxidation, the oils were heated for vary-

ing lengths of time at 100°, at 180°, and at 300° in O and in CO<sub>2</sub>. Consts. of the oils were then detd. every few hrs., and the tabulated results show that changes due to heating are largely of the nature of decompn. with some polymerization and only to a minor extent oxidation. When mixed with PbO and exposed in thin layers, the original oil showed 8.2% max. gain in wt. Raw safflower oil mixed with Mn borate dried in 66 hrs. Oil heated to 100° and especially that heated to 186° in O, showed a marked reduction in drying time, while heating to 300° retarded drying. White lead paints made with safflower oil were compared with paints made with boiled linseed oil. While heating the oil at the lower temps. decreased the drying time of the oil alone, it increased the drying time of the white paint. The paints gave a far more glossy and an equally hard coat, as the paints made with the boiled linseed oil. All exptl. results are tabulated.

F. A. WERTZ.

**History and manufacture of floor-cloth and linoleum.** M. W. JONES. *J. Soc. Chem. Ind.* 38, 26-31T(1919).—Historical review.

F. A. WERTZ.

**Determination of turpentine and the detection of adulterants.** J. TAUSZ. *Chem. Ztg.* 42, 349-51(1918); *J. Soc. Chem. Ind.* 37, 554A.—Turpentine and other unsatd. hydrocarbons combine with Hg(OAc)<sub>2</sub>, or are oxidized by it; one mol. of AcOH is set free for each mol. of terpene, etc., present and a detn. of this acidity gives a measure of the turpentine present. Ten cc. of pure turpentine and 10 cc. of the sample under examn. are each dild. with MeOH to 100 cc. (the reaction proceeds more quickly in the presence of MeOH) and 10 cc. of each of these solns. is mixed with 50 cc. of satd. HgCl<sub>2</sub> soln. (in MeOH) and 50 cc. of 0.1 N KOH soln. (also prepd. with MeOH). The mixts. are dild. with 100 cc. of water, shaken, kept in the dark for 1 hr., phenolphthalein is added, and NaCl soln. is run in until a red coloration develops; the mixts. are then titrated with 0.1 N H<sub>2</sub>SO<sub>4</sub>. A control test, without turpentine, is made at the same time. Usually, turpentine substitutes do not react with Hg(OAc)<sub>2</sub>; rosin spirit yields a small quantity of free AcOH, and if this adulterant is present, turpentine contg. approx. the same quantity as the sample should be used for the comparison titration. When pure turpentine is heated under a reflux condenser for 3 hrs. with Hg(OAc)<sub>2</sub> soln. and MeOH, and then steam-distd., no trace of oil is found in the distillate. Hydrocarbons, however, such as mesitylene, cumene, cymene, petroleum spirit, etc., pass almost quantitatively into the distillate and their quantity may be measured. The loss is about 0.2 cc. for each 10 cc. of hydrocarbon, but it varies with each app. and should be detd. separately. This method permits further examn. of the distd. adulterant. The reaction between turpentine and mercuric acetate may also be used gravimetrically. Five cc. of the sample is dild. to 100 cc. with MeOH and 5 cc. of this soln. is mixed with 50 cc. of satd. aq. mercuric acetate soln. and heated for 4 hrs. in a closed flask in a boiling water bath; after cooling, the HgOAc formed is collected, washed with alc. and ether, dried, dissolved in HNO<sub>3</sub> (1:1), the soln. treated with NaCl, and the HgCl collected and weighed. A control test is made at the same time, using pure turpentine; the quantity of turpentine in the sample is proportional to the amt. of HgCl found.

E. J. C.

**ANDES, LOUIS E.: Oil Colors and Printers' Inks.** Translated from the German. 2nd Ed. Revized and enlarged by H. B. Stocks. New York: D. Van Nostrand Co. 235 pp. \$4.

**Zinc oxide pigment.** L. E. WEMPLE. U. S. 1,292,976, Jan. 28. In prepg. a pigment, a crude ZnO which has an excess of ZnSO<sub>4</sub> and in which the Pb and Cd is present as sulfate is heated with C to a temp. of 480-650° to effect a selective action upon the ZnSO<sub>4</sub> without reduction of the Pb or Cd sulfates.

**Paints and varnishes containing coumarone resin.** F. W. SPERR, JR. and M. DARRIN. U. S. 1,292,907, Jan. 28. Coumarone resin used with coal-tar pitch in forming paints and varnishes serves to prevent deposition of the free C from the pitch on standing. Other constituents such as turpentine oil, linseed or China wood oil, Venetian red, red lead, Zn oleate, Mg resinate or BaSO<sub>4</sub> may be used in the mixts. Solvents containing coumarone or indene may be mixed with the pitch and the coumarone or indene then polymerized by heating to 160° and blowing air into the mixt.

**Paints and varnishes containing coumarone or indene resins** F. W. SPERR, JR. and M. DARRIN. U. S. 1,292,908, Jan. 28. This pat. relates to the prepn. of mixts. similar to those of the preceding pat. *E. g.*, a paint may be formed of 700 lbs. medium grade water-gas-tar pitch and 55 gals. solvent naphtha containing about 40% coumarone-indene substances.

**Drier for oils, paints and varnishes.** A. SCHWARCMAN. U. S. 1,291,185, Jan. 14. Raw or refined linseed oil 1000 parts is mixed with 50 parts of MnO<sub>2</sub>, 50 parts of PbO and 500 parts H<sub>2</sub>O. The mixt. is thoroughly churned and heated in an autoclave to a temp. of 125–160° under a pressure of 150–175 lbs. per sq. in. for 2–3 hrs. This effects a splitting of the oil and combining with Pb and Mn of part of the fatty acids liberated. The glycerol is sepd. and the fatty acid salts constitute a light-colored drier.

**Drier for linseed oil or similar oils.** A. SCHWARCMAN. U. S. 1,291,186, Jan. 14. Linseed oil or similar fatty oil is split into free fatty acids and glycerol by the Twitchell process or any other suitable method and the fatty acids are then converted into Mn or Pb salts by successive addition to them of MnCl<sub>2</sub> or Pb(OAc)<sub>2</sub> and a combining proportion of caustic alkali and heating to 115°. Large quantities of drier can be made in a single operation by this process and when about 2% of the drier is added to raw linseed oil a paint oil is obtained having the natural color of the raw oil and unchanged viscosity which may be used for the ordinary purposes of so-called commercial "boiled oil." About 0.3–1% of the metallic salts also may be combined with raw linseed oil to give it the drying properties of boiled oil without impairing its original color.

**Coating webs.** E. HAEFELY & CIE. Brit. 121,742, Dec. 19, 1918. Paper or other fibrous fabric is coated with an adhesive material for insulating purposes by applying a fusible, natural or artificial varnish or gum in powdered or solid form in a continuous operation, and then passing the fabric over a hot roller or plate or through a heated space to melt and fix the adhesive.

**Linoleum.** A. B. CRAVEN and YORKSHIRE DYEWARE & CHEM. Co. Brit. 121,777, Dec. 20, 1917. A linoleum cement is obtained by distg. either the fatty acids from drying and semi-drying oils, or the oils themselves (except tung oil), or mixts. or these substances, or by-products obtained in refining these oils, until the requisite resilient, tacky, and adhesive residue is obtained. The distn. may be effected with or without the use of superheated steam, CO<sub>2</sub>, or other inert gas, or vacuum. The distillate consists of non-polymerizable fatty acids with or without glycerol. The by-products employed are those obtained in refining oils by means of acid, alkali, or dichromate and acid, or by sedimentation, or the oily substances recovered from fuller's earth. The products are improved by bleaching the raw materials before distn. as by treatment with bleaching powder and acid, or with strong alkali. The raw materials may also be filtered in a filter press to remove solid fatty matters and impurities. An increased yield is obtained by preliminarily polymerizing the raw materials by means of heat. Gum resins, resin, etc., may be added during or after the distn. In the preferred procedure, the raw materials after a preliminary purification are heated to 270–300° for 30 min. to polymerize them, and are then distd. by means of superheated steam at temps. gradually rising from 200 to 300°, the operation taking 10–24 hr. The pre-

liminary treatment of foots may comprize washing with strong alkali and acid. Crude cottonseed oil is washed with strong NaOH. Linseed oil fatty acids are filter-pressed. The treatments of linseed oil and of soy oil is described.

**Distilling crude pine-resins.** R. DUNWODY. U. S. 1,291,800, Jan. 21. Turpentine and rosin are obtained from crude gum by passing it through strainers of different mesh, distg. the unstrained portion of the gum to sep. out rosin and passing the vapors of the distillate through the strainers to dissolve any gum present on them. The dissolved gum thus obtained is added to the strained portions originally obtained.

**Resin size.** J. A. DECREW. U. S. 1,292,721, Jan. 28. Resin size is prepd. by heating resin soap in a closed vessel, forcing it through a screen by pressure from the interior of the vessel and forcing hot  $H_2O$  against the soap as it issues through the screen.

## 27. FATS, FATTY OILS AND SOAPS.

E. SCHERUBEL.

**Saponifiable fat and total fat.** J. PRESCHER. *Z. Nahr. Genussm.* 36, 71-3 (1918); *J. Soc. Chem. Ind.* 37, 741A.—The true fat content of a material (fatty acid plus neutral fat) is best ascertained from detns. of the free fatty acids, the total fatty acids, and the sapon. value.

E. J. C.

**Determination of the oil content of oil seeds.** R. BIAZZO. Napoli. *Ann. chim. Applicata* 10, 130-3 (1918).—Com. quotations of oil seeds are based upon oil content, upon the source, age, degree of development, purity and state of preservation of the seeds themselves. Ordinarily the oil content is made by extrn. in one or another form of Soxhlet extractor. The method of extrn. is described in detail.

ROBERT S. POSMONTIER.

**Fish oils.** W. FAHRION. *Chem. Umschau* 1917, 57; *Chem. Ztg.* 42, 136 (1918); *J. Soc. Chem. Ind.* 37, 630A.—The statement by F., made nearly 25 years ago (*Chem. Ztg.* 17, 521-4 (1893)), that fish oils contd. jecoric acid,  $C_{18}H_{30}O_2$ , an isomer of linolenic acid, has been confirmed by the examn. of sardine oil. Besides the more unsatd. acid, clupanodonic acid,  $C_{18}H_{28}O_2$ , discovered by Tsujimoto (*J. Coll. Eng. Univ. Tokyo* 4, 1-9 (1906)), this oil contains jecoric acid and probably also a less unsatd. fatty acid. The occurrence in natural fats of fatty acids contg. an odd number of C atoms is still open to doubt, but later investigations make it appear possible that asellenic acid,  $C_{17}H_{32}O_2$ , isolated from liver oils, is an individual acid and not a mixt. of stearic and palmitic acids.

E. J. C.

**Utilization of plum stones for oil in Germany.** K. ALPERS. *Pharm. Ztg.* 63, 354; *Pharm. J.* 101, 151 (1918).—Examn. of the stones of plums, cherries, peaches and apricots gave the following results: Air-dry stones in plums 4.1%; cherries 7.7; kernels in plum stones 12.6%, in cherry stones 22.9, in peach stones 5.7, in apricot stones 29.2%. Oil in plum kernels 37.38%, proteins 23.78%; in cherry kernels 38.71 and 28.01; in peach kernels 45.45 and 26.01; in apricot kernels 51.43 and 28.36%. Yield of oil from plum stones 3 to 4.3%; from cherry stones 4%. Germany possesses 21 million cherry trees and 69 million plum trees, the utilization of the stones should therefore pay well. The stones can be cracked in a mill and the kernels sepd. by a soln. of  $MgCl_2$  or other salt of sp. gr. of about 1.15, in which the kernels float. Plum kernel oil will keep for years; cherry kernel oil becomes slightly rancid.

S. WALDBOTT.

**The manufacture of neutral palm oil.** LINDER AND DYBOWSKI. *Compt. rend. acad. agr.* 5, 158-9 (1919).—Announcement and discussion of work by Paul Ammann. The bunches of fruit should be detached before full maturity and immediately cooked in

H<sub>2</sub>O. Oils are thus obtained of an acidity not exceeding 0.2% instead of the 14 to 15% frequently met with.

ALBERT R. MERZ.

Experiments in preparing copra. M. B. SMITHS. *Teysmannia* 29, 128-31(1918); *Chem. Weekblad* 16, 82-3(1919).—Careful cultivation and fertilization of the trees greatly improved the quality of the coconuts and the oil yield from the copra.

JULIAN F. SMITH.

Direct determination of calcium soaps by means of solvents. E. SALM AND S. PRAGER. *Chem. Ztg.* 42, 463-4(1918); *J. Soc. Chem. Ind.* 37, 707A.—Ca soaps prepd. from bone-fat, glue-leather fat, neat's-foot oil, linseed oil, and castor oil were extd. for 16 hrs. with various solvents, and the amts. of ext. detd. In each case the soap swelled up into a gelatinous mass when heated with petroleum spirit, CS<sub>2</sub>, benzene, or CCl<sub>4</sub>, but not with AcOH or ether, so that concordant results were obtained with the latter solvents. With the exception of castor oil Ca soap (soly. 92.2%) all the soaps dissolved with difficulty in acetone. Ether had a greater solvent action than acetone, especially in the case of the neat's-foot oil and linseed oil soaps. Hence acetone should be used rather than ether for sepg. neutral fats from Ca soaps. The Ca salts of bone-fat and glue-leather fat are readily sol. in benzene and CCl<sub>4</sub>, and one of these solvents should be used instead of ether or acetone for extg. the total fat, including Ca soaps, from fatty material contg. such soaps, provided that the material does not swell up in the treatment. The soly. of Ca soaps in benzene increases with the temp., and is complete at the b. p. of the solvent after extn. during about 6 hrs. in a Besson flask. Moisture reduces the soly. so that the material should first be dried at 95 to 100°. The results thus obtained agree closely with those given by Fahrion's method (*Chem. Ztg.* 23, 452).

E. J. C.

Further note on the analysis of soap. R. LÉCOQ. Paris. *Bull. sci. pharmaco.* 25, 355-357(1918).—The detn. of total fatty acids in toilet soaps when the fats have been obtained from the wastage in the manuf. of common soap presents difficulties which are compensated for by the following procedure: Five g. of finely pulverized soap are dissolved over a boiling water-bath in a sufficient amt. of distd. water contained in a cylindrical flask of Bohemian glass. The fatty acids freed by an excess of HCl collect in a liquid layer which solidifies on cooling. The mass of this cake obtained after decantation of the underlying liquid is dried in an oven at 100-110° in a tared crystallizing dish, cooled in a desiccator and weighed. The liquid from the flask is brought to a boil and together with the particles of fatty acid sticking to the sides of the container is thrown onto a previously weighed and wet filter paper. The paper is dried, cooled, and weighed. Analyses are given of several toilet soaps. Cf. *C. A.* 12, 1707.

F. S. HAMMETT.

Analysis of clay soap. W. D. COHEN. Heemstede. *Chem. Weekblad* 16, 144-5(1919).—The large amt. of filler in clay soap makes a complete sepn. of the fatty acids difficult. Good results can be obtained by driving very thin shavings of the soap to const. wt. at 105° and extg. with 96% EtOH in a Soxhlet extractor. The clay can also be detd. by drying the thimble at 100° and weighing. The samples analyzed conformed in general quite closely to the government requirements of 20% fatty acid with a sapon. number of not less than 225, and 66% of clay.

JULIAN F. SMITH.

Determination of loss of oxygen during the use of oxygen-yielding bleaching and washing materials (GRÜN, JUNGSMANN) 25. Fat extraction apparatus (GRIFFITHS-JONES) 12. Device for determining the dropping point of fats, etc. (DUPRÉ) 1. Bolly refuse (DOWELL, FRIEDEMANN) 12. Safflower oil as a drying oil (MANN, KANTKEAR) 26. Examination of drilling oils and their substitutes (MARCUSSEON) 22.

## 28. SUGAR, STARCH AND GUMS.

A. HUGH BRYAN.

**Simplified preparation of the cuprosodic reagent for the detection and determination of sugar.** ED. JUSTIN-MUELLER. *J. pharm. chim.* 19, 18-20(1919).—To 100 cc. of NaOH soln. of 39° Baumé (d. 1.370, or 33.69%) add slowly, while stirring, 20 cc. of 10% CuSO<sub>4</sub> soln. A clear, blue soln. of permanent titer is obtained, which remains blue and limpid even when dild. with H<sub>2</sub>O and brought to boiling. It may be used in place of Fehling soln. in detn. of sugar in urine. With NaOH soln. below 37° Bé., or when increasing the amt. of CuSO<sub>4</sub> at 39° Bé., soly. diminishes, although clear solns. are obtainable down to 30° Bé.; boiling after dild. with H<sub>2</sub>O, however, causes black pptn. S. WALDBOTT.

**Note on the colloid chemistry of Fehling sugar test.** MARTIN H. FISCHER AND MARIAN O. HOOKER. *Intern. Sugar J.* 21, 76-8(1919).—See C. A. 11, 2852.

F. W. ZERBAN.

**The future sugar industry in Siam.** LEWIS S. WARE. *Sugar* 20, 490-2(1918); 21, 19-21(1919).—The article points out the many natural advantages for the development of a cane sugar industry along modern lines.

F. W. ZERBAN.

**Central Romana.** JAMES SCOTT. *Sugar* 21, 7-14(1919).—A detailed illustrated description of this modern cane mill just completed in Santo Domingo.

F. W. ZERBAN.

**Simplified calculation of stocks.** WALTER E. SMITH. *Sugar* 21, 79-80(1919).—A system of daily stock taking has been devised which permits rapid tracing of abnormal losses. All tanks are provided with floats or gage glasses and graduation marks. For some of the products in process factors were worked out experimentally. With the aid of a Monroe calcg. machine the entire operation of stock taking, through to the finished report, can be done in less than 45 min.

F. W. ZERBAN.

**Mill control.** F. W. BOLK. *Meded. Java-Suikerind. Techn. Serie* 1918, No. 1, 1-3; *Chem. Weekblad* 16, 77(1919).—A defense of a new system used in the sugar mills of the Dutch East Indies.

JULIAN F. SMITH.

**Specific gravity of fiber.** F. W. BOLK. *Med. Java-Suikerind. Techn. Serie* 1918, No. 2, 1-8; *Chem. Weekblad* 16, 81-2(1919).—A discussion of attempts to det. the sp. gr. of fiber in sugar mills. The importance of such detns. in practical work is questioned.

JULIAN F. SMITH.

**Microorganisms in the sugar mill.** W. J. TH. AMONS. *Ind. Merc.* 40, 724-5 (1917); *Chem. Weekblad* 16, 75-6(1919).—Raw cane juice contains many varieties of bacteria, the number per cc. differing widely from time to time. After it has passed the heaters, only the most resistive spores remain. Molasses generally keeps well. It sometimes contains the spores of a variety of *Aspergillus*. Deterioration of sugar is probably due to more than one kind of microorganism. Molds are known to have been responsible in some cases.

JULIAN F. SMITH.

**The effects of polyphenols in the manufacture of cane sugar in the tropics.** W. H. TH. HARLOFF. *Ind. Merc.* 40, 860-1(1917); *Chem. Weekblad* 16, 76-7(1919).—One cause of color in the treatment of cane juice is the alk. decompn. of glucose, yielding brown products. But more intense color is caused by the formation of polyphenols, which form Fe compds. If the sulfur treatment of the juice is thorough enough, no discoloration of the sugar need be feared.

JULIAN F. SMITH.

**A new conception of the theory of the clarification of cane juice.** S. S. PECK. *Intern. Sugar J.* 21, 70-2(1919).—A number of non-sugars, e. g., tannin, albuminoids

pectinous substances, silica, etc., exist in cane juice and other cane products in the colloidal state. The removal of these colloidal impurities is of great importance from the practical standpoint, and it is suggested that the application of the principles of colloid chemistry to the manuf. of cane sugar opens up an important field of research.

F. W. ZERBAN.

**The precipitation of sucrose from exhausted molasses.** J. L. M. VAN DER HORN VAN DEN BOS. The Hague. *Chem. Weekblad* 16, 141-3(1919).—In connection with the article on this subject by Prinsen-Geerligs (*C. A.* 12, 1424), attention is called to British pat. 1,817 of 1882, by J. H. Johnson.

JULIAN F. SMITH.

**Molasses formation from the standpoint of the phase rule.** F. V. D. LINDEN. *Ind. Merc.* 40, 723(1917); *Chem. Weekblad* 16, 75(1919).—From the standpoint of the phase rule, exhausted molasses is a mixt. of sucrose and several other components, satd. with respect to sucrose and 1 other component. Beet sugar molasses is generally purer than that from cane, because it contains salts having relatively high m. p. The Java refineries have not yet settled the question of whether their molasses is exhausted or not. The influence of various salts and different sugars on the soly. of sucrose should be studied.

JULIAN F. SMITH.

**Industrial alcohol from molasses.** J. P. FOSTER. *Intern. Sugar J.* 21, 75(1919).—Industrial alc. can be manufd. from molasses with little difficulty. Very active pure culture yeast, acclimated to high temp., must be used. The molasses must be sterilized, and only condensation water from the effects used for dilution. The tubs must be provided with cooling coils, and should be filled not more than half full. Very little skilled labor is required.

F. W. ZERBAN.

**Making money from bagasse.** WALTER BAUNARD. *Sugar* 21, 122-3(1919).—The price of paper is high, while fuel will probably be cheaper, on account of new oil discoveries and of new processes for the utilization of lignite and peat. Under these circumstances it would pay better to use bagasse for paper making than for fuel.

F. W. ZERBAN.

**Recovering potash and nitrogen.** ANON. *Sugar* 21, 143(1919).—In a process, credited to Oppenheim, devised to recover not only the potash, but also the nitrogen in Steffens house waste waters and similar liquors, the combustion gases from the incinerator first pass through a condenser with baffle plates, catching tar and pitch, and are then absorbed in dilute  $H_2SO_4$ . A down-draft exhaust fan at the end of the system facilitates the movement of the gases.

F. W. ZERBAN.

**An automatic forced feeding cane mill.** ANON. *Louisiana Planter* 61, 380-1(1918).—Longitudinal slots are cut in the top roll, in which are inserted bars supported by springs. The bars are prevented from coming out of the roll by a shoulder on the slot, and the slot is deep enough so that the bar recedes till flush with the roll when pressure comes on it. The device was invented by A. Erlekens. W. L. BADGER.

**Bagasse feeders, furnace design, and furnace control.** A. GARTLEY. *Louisiana Planter* 62, 25-8(1919).—Not over 50% excess air should be needed for bagasse, corresponding to 14%  $CO_2$ . Generally not over 2.5 lbs.  $H_2O$  are evapd. per lb. of bagasse, 3 lbs. at the most. With step grates, 100 to 120 lbs. bagasse per sq. ft. grate surface per hr. is the max. Necessary points in furnace design are ample combustion space, highly heated radiating surfaces to dry the entering bagasse, and baffling to prevent secondary air short-circuiting to the bridge wall. Drawings of 4 furnaces are given. For boilers of 400 horse-power or over the grate surface needed becomes excessive, and the Cuban type is better. This is essentially a producer with many air inlets around the furnace at low levels. The usual aids to boiler-room efficiency are emphasized.

W. L. BADGER.

**Cane-preparing machinery, including crushers.** ANON. *Louisiana Planter* 62, 60-3(1919).—Report of committee on machinery, Hawaiian Sugar Planters' Assoc., for year ending Sept. 30, 1918. The present equipment of Hawaiian mills is summarized and the following recommended as representing best practice: Steel slat carrier nearly same width as mill; Krajewski or 3-roll crushers of same width and diam. as mill rolls; revolving knives or cane levellers; Searby shredding system; 12-roller mill. Graphs showing data for 13 factories show wide variations: H. P. per ton cane varied from 10 to 20; % dila. from 25 to 45; tons pressure per ft. of roll, from 50 to 80; sq. ft. roll surface per ton of fiber, from 180 to 275; and H. P. per ton fiber, from 65 to 165 per cent extn. was uniform; about 98 for all factories. Variations in H. P. are not due so much to diffs. in milling methods as to diffs. in friction due to wide variations in equipment.

W. L. BADGER.

**The Searby shredder and diffusion.** W. H. TH. HARLOFF. *Ind. Merc.* 40, 1053-5 (1917); *Chem. Weekblad* 16, 77-8(1919).—It is contended that the use of the Searby shredder for sugar cane is not a good method, because the shredded cane packs together too compactly to permit proper circulation of the diffusion liquid. JULIAN F. SMITH.

**Problems of cane fertilization.** ARTHUR H. ROSENFELD. *Sugar* 21, 24-6, 61-4, 118-9(1919).—A large number of fertilizer tests made with native canes in the province of Tucuman, Argentina, from 1911 to 1914, gave such contradictory and largely negative results that no recommendations can be made.

F. W. ZERBAN.

**Report of committee on agricultural progress of the Louisiana Sugar Planters' Association for the year 1918.** STEPHEN C. MUNSON, *et al.* *Louisiana Planter* 62, 171-3(1919).—The principal developments of chem. interest are the growing appreciation of legumes and manures as soil builders, and the continued good results from the seedling L 511, which yielded 3 1/3 tons of sugar per acre.

F. W. ZERBAN.

**Soluble starch for laundry purposes.** O. REINKE. *Chem. Ztg.* 42, 422(1918); *J. Soc. Chem. Ind.* 37, 652A.—Since rice starch is no longer obtainable in Germany potato starch which has been rendered sol. is suggested as a substitute for starching collars, etc.

E. J. C.

**New top-dressing for sugar-beet (HOFFMANN) 15.** Determination of fructose in presence of aldoses (HERZFELD, LENART) 7. Cane fertilization (ROSENFELD) 15.

## 29. LEATHER AND GLUE.

ALLEN ROGERS.

**Theory and practice of leather chemistry.** JOHN ARTHUR WILSON. *J. Am. Leather Chem. Assoc.* 14, 93-102(1919).—Competition between the several tanneries is a permanent bar to any general discussion of details of leather manuf., even though the fundamental principles underlying any of the processes is known. But the individual as well as the industry as a whole is benefitted by coöperative development of basic laws. The Assoc. can therefore be of great service to the industry by stimulating theoretical discussions. Indications of how to bridge the gap between theory and practice are given by treating the subjects of the effect of hard water upon tannins, tannin analysis, and vegetable tanning. A letter from T. A. Faust is included.

J. A. W.

**Modern theories of the various methods of tanning.** LOUIS MEUNIER. *J. Am. Leather Chem. Assoc.* 13, 530-3 (1918).—See C. A. 12, 2706.

J. S. ROGERS.

**Chrome leather problems for research laboratories.** E. J. WHITE. *J. Am. Leather Chem. Assoc.* 14, 2-5(1919).—Attention is called to the following problems

which are typical problems which might be investigated by private research labs.: (1) The study of the neutralization of chrome leather; (2) the dyeing and fat liquoring of chrome leather; (3) the interference of As in 2-bath chrome tannage; (4) the adsorption of chromic acid from the first bath.

J. S. ROGERS.

Utilization of leather and horn waste, etc. (DONATH, ULRICH) 15.

"Leather substitute." M. SCHUEER. U. S. 1,291,180, Jan. 14. A "leather substitute" is formed of a carrying vehicle such as paper or a woven fabric and a facing of supple pyroxylin built up of successive layers united into an integral structure of sufficient thickness that it may be removed from the carrier. The coating may be formed of nitrocellulose 10, castor oil 20, amyl acetate 15, MeOH 20, amyl alc 5, C<sub>2</sub>H<sub>5</sub> 30 and pigment 3 parts.

Waterproofing compositions for leather. H. C. TRENAMAN. Brit. 121,587, Oct. 1, 1918. See U. S. 1,269,658 (C. A. 12, 1935).

### 30. RUBBER AND ALLIED SUBSTANCES. •

JOHN B. TUTTLE.

Gas defense equipment and the rubber industry. C. R. JOHNSON. *India Rubber World* 59, 292-301(1919).—A description of the development and manuf. of the gas masks for the U. S. Army. The article is profusely illustrated and gives considerable detail regarding the various processes.

JOHN B. TUTTLE.

Notes on cemented seams and rubber cements. JUNIUS DAVID EDWARDS AND IRWIN L. MOORE. U. S. Bureau of Standards. *Rubber Age* 4, 421-3(1919).—The authors confine themselves to a study of seams and cements used in balloons. Seams were prep'd. by washing with gasoline the surfaces of the fabrics to be cemented. Two coats of cement were applied, the second before the first had dried completely. Before the second was dry, the two surfaces were lapped for 0.5 in., rolled together with a steel roller, and allowed to set for 24 hrs. before testing. Test strips 1 in. wide were cut and suspended in an oven at a const. temp., under a tension of 1 kg., and the time required for the seam to break was noted. At room temp. the tests ran in the following order, the strongest being placed first: Al surface to Al; rubber to Al; rubber to rubber; rubber to cloth; cloth to cloth. The same relative order held up to 75°, although the differences were smaller. This was also true for increasing loads at 55°. Different widths of lap were tested at 60°; over 0.5 in. the strength increased rapidly.

JOHN B. TUTTLE.

Estimation of sulfur in vulcanized rubber. H. P. STEVENS. *Analyst* 43, 377-8 (1918).—A half g. sample is digested 2 to 3 hrs. in a Kjeldahl flask with 20 cc. of concd. HNO<sub>3</sub> and 0.5 g. of KClO<sub>4</sub>. It is evap'd. to dryness in a porcelain dish with the addition of 3 g. of Mg(NO<sub>3</sub>)<sub>2</sub>, then digested 1 hr. with 10 cc. concd. HCl, dild., filtered and ppt'd. with BaCl<sub>2</sub> in the usual way. S. concludes that the method gives the same results as the Carius method.

A. H. SMITH.

The rubber stress-strain curve. P. SCHIDROWITZ AND H. A. GOLDSBROUGH. *India Rubber J.* 57, 269-70(1919).—When subjecting a mixt. of 100 rubber: 8 S to a series of 22 cures at 141° for 15-405 min., the authors did not observe any tendency to "reversion" in the curves. With a mixt. containing less S (mixt.: 70 rubber, 27 inert filler, 3 S), vulcanized over a shorter range, they observed some tendency to reversion. These observations agree with those of de Vries and Hellendoorn (C. A. 13, 916). The authors note that, compared with the original progression of the curve

down the paper, the reversion appears to be slow. They give it as their experience that mixings containing mineral accelerators behave differently from the mixings mentioned above, on subjecting them to a series of increasing cures. The reversion of the curve up the paper is much more marked and rapid (data are lacking as to whether the reversion is coincident with complete combination of the S); the final stage of the curve changes in slope ("type"); the curve may even change in character, so that instead of being concave to the load axis it becomes convex. The phenomena discussed are in accord with the view that in the process of vulcanization two main factors are operative: (1) A process of integration, peptization, "firming up," which consists of the chem. process of combination of S with rubber, and (2) a disintegration or degrading process due to the heat effect as such. When further combination with S is no longer possible, the heat effect becomes apparent and causes reversion or degradation. The authors suggest that a study of the reversion of the stress-strain curves should be of value in permitting a rapid and accurate estn. of over-heating as opposed to over-curing in the manuf. of goods cured with minimum proportions of S. G. S. WHITBY.

Further data on the moisture content of plantation rubber. O. DE VRIES. *Archief Rubbercultuur* 2, 852-60(1918); *Med. Centraal Rubberstation* No. 12, 1-9; cf. Whitby, C. A. 12, 2710.—Data are given showing that procedures (such as dilution of the latex, soaking freshly rolled crepe or sheet in water, rolling the coagulum on the day of coagulation instead of on the following day) which result in a reduction in the amt. of serum solids in the rubber lower the amt. of moisture retained. The presence of  $\text{NaHSO}_4$  causes some increase in the moisture content. G. S. WHITBY.

The changes in vulcanized rubber during the first days after vulcanization. O. DE VRIES and W. SPOON. *Archief Rubbercultuur* 2, 807-16(1918); *Med. Centraal Rubberstation*, No. 11, 39-48.—The authors find that the figures obtained for tensile strength are identical whether the period of rest between curing and testing is 1, 2, 3, 4 or 5 days. The position of the stress-strain curve was influenced by the length of the period of rest, but only to a very slight extent; the curve obtained after 24 hrs. was higher than that obtained after 72 hrs. by an amt. represented by 5-10% length at 1.30 kg. and corresponding to 2-3 min. on the cure. Comparing the results after 24 hrs. among themselves: they were quite as regular as those obtained after a longer rest compared in the same way. From Jan. 1, 1918 on, the Centraal Rubberstation has adopted a rest of only 24 hrs. in their testing work. G. S. WHITBY.

Changes in vulcanized rubber at elevated temperature. O. DE VRIES. *Archief Rubbercultuur* 2, 792-806(1918); *Med. Centraal Rubberstation*, No. 11, 24-38.—This extends the work given in C. A. 11, 1335. The author studies particularly the changes in the tensile strength and the position of the stress-strain curves produced in mixt. of 92.5 rubber: 7.5 S which have been cured at  $148^\circ$  for periods of 70, 90 and 110 min. by subjecting them to artificial aging tests consisting of heating for periods up to 16 days at  $65^\circ$  and at  $72^\circ$ . The stress-strain curve is found to shift its position in a way analogous to that brought about by continued curing at  $148^\circ$ . The extent of the shifting during the first day is smaller, the longer the sample has been cured; but during the following days the changes for the differently cured samples are parallel. The change in the tensile strength also is similar to that produced by prolongation of curing at  $148^\circ$ , but the magnitude attained before a drop sets in is not so high. Briefly, the curves come down the paper as with prolongation of the curing, but become shorter in length than those given by prolongation of the curing. The following are actual results: A sample cured for 70 min. and then "aged" at  $72^\circ$  for 24 hrs. gave a curve and tensile strength approx. the same as those produced by curing for 90 min., but the coeff. of vulcanization was 2.3 as compared with 3.09. Another sample cured for 70 min. gave after aging at  $65^\circ$  for 73 hrs. a curve and tensile strength identical with those produced

by curing for 90 min., but the coeff. of vulcanization was 2.42 as compared with 2.82. In both cases prolongation of the aging beyond this point reduced the tensile strength, whereas prolongation of the curing increased it.

G. S. WHITBY.

**Rubber substitutes.** ANON. *Caoutchouc & gutta-percha* 16, 9709(1919).—During the war, the use of the term "substitute" for vulcanized oils gave considerable trouble in France, especially with those officials who were not familiar with the technology of the rubber industry. Since these oils are not substitutes, but are used on account of the special properties which they impart to rubber compounds, it is urged that the term "substitute" be dropped because it is misleading.

JOHN B. TUTTLE.

**Chrysanthamnus or Sierra rubber.** ANON. *India Rubber World* 60, 349-50(1919).—Among the native wild plants containing rubber, "Common Green," a variety of *Chrysanthamnus naseousus*, is mentioned as a possible source of rubber, especially should importations be stopped for any cause. It could not be produced to compete with plantation rubber at the present market price. Tests by Spence show that it is of good quality, better than most African rubbers, and vulcanizes readily.

JOHN B. TUTTLE.

**Rubber cultivation in the Philippines.** HENRI JUMELLE. *Caoutchouc & gutta-percha* 16, 9703-4(1919).—A review of the development of the rubber plantation industry in the Philippines.

JOHN B. TUTTLE.

**Analysis of antimony pentasulfide.** D. REPNY. *India Rubber World* 60, 360-1 (1919).— $\text{Sb}_2\text{S}_5$  is tested for adulteration by treating 5 g. in 100 cc. 10% NaOH soln. with heating on steam bath until no red particles are observed; any red insol. particles indicate adulteration. A white residue may be  $\text{CaSO}_4$ ,  $\text{CaCO}_3$ ,  $\text{BaSO}_4$ ,  $\text{SiO}_2$  or  $\text{Sb}_2\text{O}_4$ .  $\text{Sb}_2\text{S}_5$  should be about 4.20 sp. gr., and neutral or less than 0.01 % acid. For acidity, place 2 g. in a filter and wash with water until the latter is neutral; then titrate with 0.1 N NaOH, with phenolphthalein as indicator. For free S, ext. 5 g. with redistd.  $\text{CS}_2$  for 10 hrs. Dry the ext. at 60°, weigh the free S and reserve for other tests. Take  $\frac{1}{5}$  of the residue, dry at 100° to const. wt. to det. moisture and water of crystn. Test qual. for  $\text{CaSO}_4$  by shaking a small portion of the sample with water, filter and add  $\text{BaCl}_2$  soln. If no ppt. is obtained the  $\text{Sb}_2\text{S}_5$  is ready for further investigation; otherwise proceed as follows: Take  $\frac{1}{5}$  of the residue from the free S detn., place on a filter and wash with cold water until nothing further is extd.; then dry in weighed beaker at 100° and weigh the  $\text{CaSO}_4$ . Transfer the residue on the filter to a beaker, add 100 cc. 10% NaOH and heat 10 min. on steam bath. If complete soln. is obtained further analysis is unnecessary. If not, allow the residue to settle, decant, add 50 cc. water and filter. Wash until neutral. Wash the residue on the filter into a weighed beaker, allow it to settle, decant, and dry the remainder to const. wt. This gives total adulteration. Red color indicates  $\text{Fe}_2\text{O}_3$ ; white may be  $\text{BaSO}_4$ ,  $\text{CaCO}_3$ ,  $\text{Sb}_2\text{O}_4$ ,  $\text{MgCO}_3$ , etc. Make qual. tests for these constituents.

JOHN B. TUTTLE.

**Vulcanizing rubber.** W. A. GIBBONS. U. S. 1,291,828, Jan. 21.  $\beta$ -Dinitroanthraquinone is added to rubber in the proportion of about 3-30% to serve as a vulcanizing agent; preferably PbO is used as an accelerating reagent, at a temp. of 140-150° for 1-2 hrs.

**Brake-lining fabric impregnated with rubber.** C. H. OAKLEY. U. S. 1,292,027, Jan. 21. Asbestos yarns are treated with a rubber soln. to coat them with rubber, the solvent is allowed to evap., powdered starch is applied to the yarns as a lubricant to facilitate weaving, and, after weaving, the fabric is subjected to a vulcanizing treatment.

# CHEMICAL ABSTRACTS

Vol. 13.

MAY 20, 1919.

No. 10

## I. APPARATUS.

L. C. JONES.

**Substitutes for platinum in electrolytic apparatus.** PAUL NICOLARDOT AND JEAN BOUDRET. *Bull. soc. chim.* 25, 84-6(1919).—Continuation of a previous article (cf. *C. A.* 13, 677). As a cathode the authors found an alloy of 90% Au and 10% Cu quite satisfactory. A cylinder 50 mm. diam., 65 mm. high and weighing 23.5 g. lost 1 mg. after 20 detns. (Cu in  $\text{HNO}_3$  or  $\text{H}_2\text{SO}_4$ ; Ni in  $\text{NH}_4\text{OH}$ ; Sb in  $\text{Na}_2\text{S}$  and  $\text{NaCN}$ ). The only precaution to be observed is to avoid heating in a flame. The same alloy was found suitable as the anode after being electrolytically coated with a thin layer of Pt and then carefully polished and burnished. F. W. SMITHER.

**Hydrogen recorder.** ANON. *Chem. Met. Eng.* 20, 191(1919).—A falling Hg column samples the gas and furnishes the driving force for passing it through the app. The outside source of power may be air or  $\text{H}_2\text{O}$ . The gas is passed through a cartridge in an elec. oven which oxidizes the  $\text{H}_2$ , and the resulting contraction is measured. W. L. BADGER.

**An electrical precipitator for analyzing smokes.** R. C. TOLMAN, L. H. RYERSON, A. P. BROOKS AND H. D. SMYTH. *J. Am. Chem. Soc.* 41, 587-9(1919).—The app. consists essentially of a modified Cottrell precipitator with a central wire as cathode surrounded by a cylindrical foil as anode. The smoke to be analyzed is drawn through the app. at a known rate and the particles are pptd. on the foil by means of high voltage d. c. The concn. is calcd. from the increase in wt. of the foil and the vol. of air passed through. The foil was exceedingly light so that the material pptd. should form a considerable part of the total weight. Al foil 0.001 inch thick was satisfactory. It is also important to have the wire exactly centered to prevent sparking, and this was further prevented by threading the wire with a jeweler's die. E. B. MILLARD.

**Laboratory furnaces.** ANON. *Elec. Rev.* 74, 524-5(1919).—A small crucible furnace, a horizontal tubular furnace and a muffle furnace are illustrated. All types can be regulated by external rheostat to give const. temps. up to  $995^\circ$ . They are well built and may be mounted on any convenient surface. The crucible furnace has a chamber 6.87 cm.  $\times$  5.24 cm. and requires 350 w. at 110 v. The muffle type has wide application, but is ideal for treatment of delicate dies and tools where exact temp. control is essential. W. H. BOYNTON.

**Effective improvized gas-washing apparatus for laboratory use.** ANON. *Gas World* 70, 121(1919).—The app. consists of an ordinary 12-pear fractionating column, sealed at the lower end. Fitted in the top is a one-hole rubber stopper through which passes a glass tube, bent at right angles and reaching nearly to the bottom of the app., serving as the gas inlet. The liquid for washing the gas should reach, when no gas is passing, about as high as the third or fourth pear. The gas can be passed through at a rate of 5 cu. ft. per hr., using a  $\frac{3}{16}$ -in. bore tube as inlet, without losing any of the liquid by spraying and at the same time insuring complete absorption. The app. is a very efficient washer but is not suitable for gas at low pressures owing to the heavy

seal required. This difficulty may be overcome by working the app. in a sloping position, or by applying a small amt. of suction at the outlet. J. L. WILEY.

Continuous vacuum still for "mustard gas." ELFORD STREETER. *J. Ind. Eng. Chem.* 11, 292-4(1919); illus. F. W. SMITHER.

A new simple device for sampling. L. F. RILEY. *J. Soc. Chem. Ind.* 38, 598 (1919).—This device is particularly suitable for sampling dust (e. g., blast-furnace dust), loose soil, and the like. The end *e* (see sketch) of a tapering tube *a* of suitable dimensions is inserted into the material to be sampled and pushed to the bottom with a rotary motion by means of the easily removable handle *b* inserted through the 2 holes *c*, and then withdrawn. The sample is then obtained by removing the handle and inverting the tube. The samples obtained from various parts are then mixed in the usual manner. F. W. SMITHER.

An automatic compensating flow meter. G. G. OBERFELL AND R. P. MASS. *J. Ind. Eng. Chem.* 11, 294-6(1919).—The authors describe in detail, with drawing, a flow meter which was intended primarily for accurately controlling the gas concn. of gas-air mixts. F. W. SMITHER.

Accurate timing in electrical tests. F. A. KARTAK. *Elec. World* 73, 672-5(1919).—K. discusses stop watches and their inaccuracies for accurate measurement of short-time intervals, and describes tuning fork app. used at the Univ. of Wisconsin. It consists of the tuning-fork timing device developed at the Bur. of Standards with several modifications to increase its accuracy and reliability.

To eliminate any change in rate due to "fatiguing" of the steel fork blades, an electrochrome-silico-manganese spring steel of the following compn. was used: C 0.43, Si 0.65, Mn 0.85, Cr 0.9, P 0.018 and S 0.015%. A Hg contact is noiseless and eliminates the use of spring or metallic contacts, which would react mechanically on the fork. The counter consists of a high-grade clock mechanism in which the balance wheel and hair spring are replaced by the moving element of a polarized telephone ringer in such a manner that this moving element actuates the escapement of the clock. The action of the polarized relay taking place at the rate of 40 movements per sec. releases the escapement of the clock at the same rate and with the clock hands properly geared, causes a corresponding indication over the dial to take place. The temp. coeff. of the fork is 0.011% per degree. Time is measured in steps of 0.025 second and personal errors preclude the necessity of an increase in the beat of the fork, though it appears possible to increase it to 0.01 second. After being started manually, the fork is operated by a 110-v. d. c.

W. H. BOYNTON.

The use of standard dies in making ground-glass joints. S. F. ACKER. *J. Ind. Eng. Chem.* 11, 338-9(1919).—The author discusses the advantages of standard dies and describes the procedure adopted in his lab. F. W. SMITHER.

Nonsilverable containers for silvering mirrors. HERBERT E. IVES. *Science* 49, 330(1919).—The use is suggested of Se as a lining material of vessels for this purpose. Cf. Coblenz, *C. A.* 12, 2263; 13, 677. E. J. C.

Points in pump selection. B. N. EVERETT. *Chem. Met. Eng.* 20, 246-7(1919).—An outline is given of the points affecting the choice of a pump as follows: *Liquid to be pumped*—sp. gr., temp., viscosity, size and nature of suspended matter. *Total head*—pipe size, actual lift, pipe friction (to be considered on both suction and discharge

lines). *Capacity*—max. demand, av. demand, storage capacity, breakdown service, hrs. service per yr., advisable speed. *Power*—type available, reliability, amt. required, control, cost per 1000 gals., cost per yr., cost compared to investment. *Total cost*—pump, driver, piping, installation, labor, fixed charges, use of exhaust steam, efficiency, fuel consumption. Several instances are given illustrating the significance of these points.

W. L. BADGER.

**Vacuum electric apparatus.** H. A. NEWCOMB. U. S. 1,293,881, Feb. 11. An arc shield of alundum is used in vacuum elec. app. such as vapor arc rectifiers or X-ray tubes. The alundum shield may be retained within and in close contact with a receptacle formed of glass having a coeff. of expansion of 0.00036.

**Acetylene lamps.** A. L. HANSEN. Can. 189,455, Apr. 1, 1919. A generator adapted for use in miners' camps has a water tube extending from the water chamber to the carbide chamber and having its lower end formed to operate as a valve in a valve seat in the carbide chamber.

**Pyrometer.** G. F. MACHLET. U. S. 1,294,688, Feb. 18.

**Centrifugal apparatus and method of operating for forming tubular filaments of pitch, asphalt or similar materials.** R. P. PERRY. U. S. 1,293,535, Feb. 4.

**Apparatus for filtering water or other liquids.** C. S. SMITH. U. S. 1,293,649-50-1, Feb. 4.

**Distributing pulverulent lining in a soaking pit.** T. D. HODGE. Can. 189,098, Mar. 11, 1919. Pulverulent lining material is supported at the open top of the soaking pit and showered down upon the bottom of the pit in such a manner as to form troughs at opposite sides of the pit. App. is also specified.

**Distillation apparatus.** WM. PERRY. Can. 187,741, Dec. 3, 1918. Structure.

**Filler for gas- and liquid-reaction and contact towers.** A. M. WEBB. U. S. 1,293,270, Feb. 4. Reaction towers such as those used for the manuf. or concn. of  $\text{H}_2\text{SO}_4$ ,  $\text{HNO}_3$ , or  $\text{HCl}$  are filled with cylinders, each of which has a helical flange projecting from its inner wall. The flange is of less width than the radius of the cylinder, so that a continuous central opening is provided extending lengthwise through the cylinder.

**Light-filter.** H. T. CLARK. U. S. 1,293,039, Feb. 4. A light-filter for absorbing blue-violet and ultraviolet light is formed of gelatin or other light-transmitting material containing a salt of glucosephenylosazone-*p,p'*-dicarboxylic acid.

**Roasting furnaces.** F. J. BOWMAN. Can. 189,453, Apr. 1, 1919. A roasting furnace having horizontal chambers has ore supply passages extending vertically into each chamber and deflecting arches forming the lower portion of the passages. The descending material forms a pile against the arch member and thus seals the chamber at that point.

**Muffle furnaces.** T. W. S. HUTCHINS. Can. 189,105, Mar. 18, 1919. A series of chambers surrounding a gas producer has a muffle furnace in each chamber, the chambers are in intercommunication and each is connected with the producer. Each chamber has a port for the inflow of air to and the outflow of waste gases from the chamber. A control valve is placed in each of the communication ducts or ports.

## 2. GENERAL AND PHYSICAL CHEMISTRY.

WILLIAM D. HARKINS AND E. B. MILLARD.

Robert Marc. H. FREUNDLICH. *Kolloid-Z.* 23, 81-5(1918).—A bibliography accompanies this obituary.

E. J. C.

The investigations by (Eduard) Jordis. M. K. HOFFMANN. *Kolloid-Z.* 23, 49-56(1918).—A bibliography accompanies this obituary. E. J. C.

Chemical research in the various countries of the world. E. J. CRANE. *J. Ind. Eng. Chem.* 11, 378(1919); cf. *C. A.* 12, 644.—A table shows the numbers and percentages of abstracts published by *Chemical Abstracts* during 1913, 1917 and 1918, resp., classified according to countries in which the papers reviewed originated. E. H.

The training of the chemist. EDWARD ELLERY. *J. Ind. Eng. Chem.* 11, 375-7(1919); cf. *C. A.* 13, 390. E. J. C.

The functions of a research laboratory. SAUL DUSEMAN. *Can. Chem. J.* 3, 118-21(1919).—An address in which are described the internal organizations and some of the successes of the research lab. of the Gen. Elec. Co. E. J. C.

First report of the Chemist's Organization Committee. M. A. PARKER, *et al.* *Can. Chem. J.* 3, 116-7(1919).—Recommendations in detail are given. These include the formation by Canadian chemists of a new organization to be known as "*The Institute of Chemistry of Canada.*" Objects are set forth. E. J. C.

Elements in the order of their atomic weights. RAYMOND SZYMANOWITZ. *Chem. News* 117, 339-40(1918).—Approx. values of at. wts. are found by alternately adding 3 and 1 to the at. wt. of H. In the resulting series of progressive numbers from 1 to 240 there are 121 numbers of which 66 correspond fairly well with detd. at. wts., 17 do not coincide with at. wts. and 38 numbers have no corresponding at. wts. and should indicate unknown elements. INGO W. D. HACKH.

\* Elements in the order of their atomic weights. F. H. LORING. *Chem. News* 117, 352(1918); cf. preceding abstract.—Attention is called to the Rydberg scheme (*Z. anorg. Chem.* 14, 66-102(1897)) and the calcns. of Comstock (cf. *C. A.* 2, 1913). The matter might be of interest provided one wishes to extend the scheme of isotopes to the non-radioactive elements. INGO W. D. HACKH.

Relation between the atomic weights of the chemical elements, densities, and heats of reaction. K. FEHLER. *Physik. Z.* 19, 281-6(1918).—It is assumed that the mols. of all elements are built up of the same fundamental units, which F. calls "atoms," and that the mol. is a homogeneous sphere filled with these "atoms" which rotate with a common angular velocity  $w$  about a common middle point. It is further assumed that the energy of a mol. of radius  $R$  is given by the equation  $U = CNw^2R^3$  and its mass by  $m = KNw$ . From these assumptions the following equation is derived for the heat of reaction when  $x$  mols. of one element unite with  $y$  mols. of another to form  $z$  mols. of a compd.:  $W = (1.534/z)[xA_1(\sqrt[3]{1/s_1} - \sqrt[3]{1/s_2} \sqrt{A_2/A_1}) + yA_2(\sqrt[3]{1/s_2} - \sqrt[3]{1/s_3} \sqrt{A_3/A_2})]$  kg. cal., in which  $s_1$ ,  $s_2$  and  $s_3$ ,  $A_1$ ,  $A_2$  and  $A_3$  are the densities and mol. wts. of the elements and compd., resp. In the case of metallic compds. the result must be multiplied by the sum of the valencies of the elements in order to give the heat of reaction for 1 mol. A table is given which compares the measured heats of reaction with those calcd. from this equation. In some cases fair agreement is obtained.

D. MACRAE.

The Neumann-Kopp law. FRIEDRICH BÜRKI. *Helvetica Chim. Acta* 2, 27-38(1919).—This law, somewhat differently stated by each of the 2 authors, has to do with the constancy of the at. heat of different elements, alone and in compds. It is usually stated for  $C_p$ . Bürki computes  $C_v$  for numerous substances by means of the usual formula involving expansion and compressibility. His data for  $C_p - C_v$  for the elements are as follows, given as differences in the atomic heats: Li 0.307, C very small, Na 0.53, Mg 0.15, Al 0.26, Si 0.26, P 1.59, S 0.29, K 0.63, Fe 0.13, Ni 0.25, Cu 0.23, Zn 0.34, Bi 0.08, As 0.01, Se 0.32, Br (liquid) 4.35, Ag 0.27, Cd 0.36, Sn 0.33, Sb 0.07, I 0.88, Cs 0.12, Pt 0.22, Au 0.27, Hg 0.92, Tl 0.38, Pb 0.33. Within any group of ele-

ments there is an increase of  $C_p - C_v$  with at wt. The N.-K. law is then tested for  $C_v$  with halides and various org. compds. with results whose considerable variability seemed to be partly chargeable to the fact that the elements were either gases or the diamond, whose values of  $C_p - C_v$  are not fairly comparable with those of the solid compds.

Equation of state for liquids and vapors. I. The vapor phase of ethyl ether. FREDERICK G. KEYES AND WILLIAM A. FELSING. *J. Am. Chem. Soc.* 41, 589-96 (1919); cf. C. A. 11, 2846.—A detailed discussion is given of equations of state, and the requirements of a satisfactory equation are reviewed. The older data for  $\text{Et}_2\text{O}$  have been reviewed with respect to Keyes equation of state,  $p = RT/(v - \delta) - A/(v - l)^2$  where  $\delta = \beta e^{-\alpha/v}$  and  $\beta, \alpha, A$  and  $l$  are consts. This equation is valid in case one type of atom or mol. alone is present, and the consts. become functions of the degree of association or dissociation in case either takes place. New measurements of the temp. and pressure corresponding to various sp. vols. have been made over a considerable range of temp. and vol. The isometrics are linear within the limits of accuracy of the measurements. It is indicated that in any system linear increase of pressure with temp. increase at const. vol. is the only reliable test for a single type of mol. and that departure from the linear isometric is due to polymerization or to change in the mol. system under consideration. The data of Amagat on liquid  $\text{Et}_2\text{O}$  have been discussed with reference to the equation for  $\delta$  (liquid phase) on the assumption that 2 of the vapor phase mols. associate in the liquid state to form a new mol. species  $[(\text{C}_2\text{H}_5)_2\text{O}]_2$ .

E. B. M.

Influence of the finite volume of molecules on the equation of state. M. N. SHAHA AND S. N. BASHU. *Phil. Mag.* 36, 199-202 (1918).—The departure of the actual behavior of gases from the ideal state defined by the equation  $p = NK\theta/v$  is due to: (1) the finiteness of the vol. of the mols., and (2) the influence of the forces of cohesion among the mols. This was first expressed by van der Waals. In subsequent modifications of van der Waals' equation of state, the changes proposed all relate to the influence of the cohesive forces, the finiteness of mol. vol. being generally left untouched. The exptl. results, however, do not agree with theoretical predictions of  $a$  and  $b$  regarded as absolute consts., and, accordingly, these have been considered as functions of temp. and vol. The present authors now examine whether the influence of finite mol. vols. is properly represented by the term  $b$ , and conclude that such is not the case. A more detailed investigation is promised with respect to the variability of the vol. of mols. with temp. Meanwhile the factor  $c = a/\sqrt{K\theta}$  has been introduced into the expression for  $p$  as a provisional measure.

S. C. LIND.

Determination of surface tension (free surface energy), and the weight of falling drops: the surface tension of water and benzene by the capillary height method. WILLIAM D. HARKINS AND F. E. BROWN. *J. Am. Chem. Soc.* 41, 499-524 (1919).—The surface tensions of  $\text{H}_2\text{O}$  and of  $\text{C}_6\text{H}_6$  at  $20^\circ$ , each against air satd. with its own vapor, were carefully detd. by the capillary rise method, using tubes selected and calibrated with great care, and numerous precautions too detailed to appear in an abstract. The values for water were:  $\gamma = 72.800$  dynes/cm.;  $a^2 = 14.897$  sq. cm. and for  $\text{C}_6\text{H}_6$   $\gamma = 28.80$  dynes/cm.;  $a^2 = 6.713$  sq. mm. One of the features of the work was the steaming out of the tubes with the vapor of the substance. This increased the value of  $\gamma$  for

water about 0.1 dyne.  $\text{H}_2\text{O}$ ,  $\text{C}_4\text{H}_8$ ,  $\text{CCl}_4$ , and  $\text{C}_2\text{H}_5\text{Br}$  were dropped from a large number of tips of glass and metal with radii varying from 0.09946 cm. to 1.0028 cm., and the weights of the falling drops detd. From these data ( $r/a$ ) and corresponding values of  $f(r/a)$  for the Lohnstein equation  $Mg = 2\pi r\gamma f(r/a)$  were calcd. When ( $r/a$ ) varies  $f(r/a)$  is not const.; in general the latter rises when the former decreases in value.  $M$  is the mass of the drop,  $g$  has the usual meaning,  $r$  is the radius of the tip and  $a$  is the capillary const. In the equation  $a$  may be replaced by any other quantity which varies as a linear dimension of the drop. A new equation in which  $f(r/a)$  is replaced by  $\psi(r/V^{1/3})$  is recommended as more readily applied to the detn. of surface tension since all the factors except  $\gamma$  are obtained by expt. or reference to a table. Variations in density over a wide range and in viscosity over a moderate range did not appreciably affect the results obtained for the surface tension of liquids by the drop weight method. The wt. of a drop varies rapidly with its time of detachment; in general the time should be 5 min., but in some cases 30 min. or more was required for dil. solns. Open, thin-walled tubes when used as tips do not give as accurate results as heavy tubes or perforated disks. The precision of the method is now about 0.1%. An important source of error is that due to lack of sharpness, or to departure from the circular shape, of the tip. Other important sources of error to be avoided in drop-weight work are pointed out in detail.

E. B. MILLARD.

Some formulas concerning surface tension. ARTHUR C. LUNN. *J. Am. Chem. Soc.* 41, 620-1(1919); cf. Harkins and Brown, preceding abstract.—H. and B. in their tabulation of measurements of surface tension have used 2 alternative formulas connecting the weight of a drop with surface tension and other properties of the liquid. One of these is understood as chiefly empirical in origin, the other was previously deduced by Lohnstein on the basis of a solution by mechanical quadrature of the differential equation of the meridian curve. The principle of dynamical similitude alone leads to equations of the 2 types used by Harkins and Brown. L. suggests extensions of the equations which may be needed in more general cases. It seems possible that viscosity might have some influence.

E. B. MILLARD.

The critical temperature and pressure of mercury and phosphorus. J. J. VAN LAAR. *Z. anorg. allgem. Chem.* 104, 126-33(1918).—See C. A. 12, 875. E. J. C.

Experimental determination of the fictive heat of solution. ERNST COHEN AND H. R. BRUINS. *Z. physik. Chem.* 93, 43-58(1918); *J. Chem. Soc.* 114, II, 297-8.—The fictive heat of soln. is the heat produced when 1 mol. of a substance dissolves in an infinite amt. of its own satd. soln. Four methods for finding this are described, all of which depend on the use of a cell, in which the energy change accompanying infinitesimal changes of concn. can be measured by means of the e. m. f. Electrodes reversible with respect to one or other of the 2 ions are used. In the first method the differential e. m. f. of 2 sep. cells is used, one of which has satd. soln. with no solid, the other a very dil. soln. where heat of soln. can be directly measured. The passage of current in either cell causes the same action, except that the deposited ions go to or from a soln. of different concn. The chem. energy of the cell is thus the difference of the heats of soln. of the satd. and of the already measured soln. and this energy can be found by means of the Gibbs-Helmholtz equation, from the e. m. f. and the temp. coeff.  $dE/dT$ , of e. m. f. of the combination. The second method substitutes a single 2-fluid cell. Here the contact potential between the 2 solns. is a complication. The third method compares satd. solns. with and without solid phase. Here the difference in action is that in one cell there is transfer of material from solid phase to soln.; the chem. energy is the required fictive heat of soln. The fourth method detd.  $dE/dT$  by the relation  $(dE/dT)_1 - (dE/dT)_2 = (dE/dC)_T(dC/dT)$ , that is by detg. the change of e. m. f. with concn. and the variation of soly. with temp. This method was applied to  $\text{CdI}_2$ . The soly'

is:  $C = 44.18 + 0.0828t + 0.000183t^2$ .  $E_{18} = 0.43150 + 0.000283C - 0.00001428C^2$ .  $F$  comes out  $-1227$  small cal. at  $18^\circ$ , against  $-1246$  by method 3. W. P. WHITE.

**Relation between intensity of Tyndall beam and size of particles.** RICHARD C. TOLMAN, R. H. GERKE, A. P. BROOKS, A. G. HERMAN, R. S. MULLIKEN AND H. DEW. SMYTH. *J. Am. Chem. Soc.* 41, 575-87 (1919).—The method consisted in setting up a smoke of rosin in a confined space and making a set of simultaneous measurements of its Tyndallmeter reading and its concn., using the Tyndallmeter described in *C. A.* 13, 923. The general result of the work is to show that for the range of particles in actual smokes ( $5 \times 10^{-6}$  to  $10^{-4}$ ) and for particles in suspensions  $10^{-4}$  cm. in diam. up, the Tyndall beam becomes more intense at a given concn. the greater the subdivision. The suspensions were prepd. by mixing ground silica with water and carrying out fractional settlings and centrifugations. Size of particles was detd. by measurement with a micrometer microscope after evapg. a few drops of the suspension; concn. was detd. by evapg. larger samples and weighing the residue. In these expts. the intensity of the Tyndall beam increased with the subdivision. A discussion of these results and those of Mecklenburg (*C. A.* 9, 2831) with particles of  $S$  smaller than those used in these expts. is given. In accordance with Rayleigh's law the Tyndallmeter reading increases are proportional to the cube of the diam. of the particle; but for larger particles the reading is proportional to the number of particles and to their reflecting surface.

**Investigations dealing with the state of aggregation. IV. The flocculation of colloids by salts containing univalent organic ions.** S. B. SCHRYVER AND NITA E. SPRUE. *Proc. Roy. Soc. London* 90B, 400-14 (1919).—Detn. was made of the pptg. capacity of salts containing org. ions, the  $N$  solns. of which exhibit wide variations in their surface tensions. The salts used were (a) the Na salt of:  $\text{HCOOH}$ ,  $\text{AcOH}$ , mono-, di-, and trichloroacetic, lactic, salicylic, benzoic, and benzenesulfonic acids; (b)  $\text{NaCl}$ ,  $\text{NH}_4\text{Cl}$ , and the hydrochlorides of:  $\text{MeNH}_2$ ,  $\text{Me}_2\text{NH}$ ,  $\text{Me}_3\text{N}$ ,  $\text{Et}_3\text{N}$ , iso- $\text{AmNH}_2$ ,  $\text{C}_6\text{H}_{13}\text{NH}_2$ , benzylamine, and piperidine. The colloidal solns. included those of  $\text{Fe}(\text{OH})_3$ ,  $\text{Zr}(\text{OH})_4$ ,  $\text{Ce}(\text{OH})_4$ ,  $\text{As}_2\text{S}_3$ , Victoria blue B, azo-blue, brilliant Congo-red R, scarlet Au sol, and mastic. "In general, no relationship was found to exist between the surface tensions of the  $N$  solns. and the flocculating capacity of salts. When a series of salts was compared in which the varying ion was not the active pptg. ion, the pptg. limits were all within a comparatively narrow range, in spite of the wide variations of the surface tensions of the solns. In the series, when the varying ion was the active ion, the range was large, although the pptg. capacity could not be generally correlated with the surface tension. The marked exception to this statement was shown in the case of mastic, when pptd. by the (hydro) chlorides. In this case the salts of low surface tension exhibit the greater flocculating power (with the exception of  $\text{NEt}_4\text{Cl}$ ). It is suggested that suspensoid colloids may be subdivided into classes; (a) those, like  $\text{Fe}(\text{OH})_3$ , which owe their charge to association with 'active' ions derived from salts from which they have been prepd., which are removed during aggregation, which results finally in flocculation, and which may be termed 'exionic colloids;' (b) those owing their charge to the dissociation of the colloid itself, in which a rapidly diffusing ion (such as  $\text{H}$  ion) forms the outer layer, and is held electrostatically to a less diffusible ion. These may be termed 'endionic colloids.' Mastic is probably a colloid which belongs to this class."

JOSEPH S. HEPBURN.

**The institute for research on colloids of the "Neuburg Foundation."** H. BRCH-HOLD. *Kolloid-Z.* 22, 44-6 (1918).—An illustrated description. E. J. C.

**Oil films on water.** G. ERCOLINI. *Nuovo cimento* 15, 49-88 (1918); *Sci. Abstracts* 21A, 481.—E. discusses in detail the exptl. difficulties of observations; and

concludes that it is only known with certitude that the min. thickness is of the order of a mol. diam. (about  $1 \mu\mu$ ); that on diminishing the area of such a film there is a formation of microglobules, but it is not possible to say whether the whole of the film is transformed into these; and the thickness of a film in presence of an excess of oil depends on the conditions of its formation, but the method of max. distension used in order to det. this thickness is lacking in precision.

E. J. C.

**Measurement of the thickness of film formed on glass and sand.** EARL PETTJOHN. *J. Am. Chem. Soc.* 41, 477-86(1919).—About 200 g. of the air-dried sample of river sand was weighed and transferred to a flask closed by a stopper bearing a weight-buret. Liquid was run in a drop at a time and the flask was thoroughly shaken after each drop until a final addition of liquid caused several of the grains to stick to the walls of the flask. The weight of liquid gave the amt. used when a film of max. thickness formed. Similar expts. were made with glass pearls and sands of different mesh. The surface was measured by counting and weighing 5000 or so grains, detg. the sp. gr., and calcg. the area on the assumption that the grains were spheres. Several org. liquids were studied in the same connection. Evidence is presented to show that the liquid forming the film does not combine chemically with the solid. The thickness of film formed is independent of the liquid used and of the size of the solid particles.

E. B. MILLARD.

**Experimental study of the development of crystals.** RENÉ MARCELIN. *Ann. phys.* 10, 185-8(1918).—By an optical method, the details of which are not given, crystalline layers so thin that they show Newton's rings are examd. It is possible not only to obtain evidence of the existence of the net-planes, but actually to measure the distance between them: Growing crystals are studied. In the case of crystals of *p*-toluidine growing from an alc. soln. the growth is by small additions of constant thickness to the faces, this thickness being of the order of three mols. In the process of soln. the reverse is true, except that different layers are of different thickness, being on the whole thicker than in growth.

**Calculation of the extraordinary rays of certain structures of anisotropic liquids.** F. GRANDJEAN. *Compt. rend.* 168, 91-4, 408-10(1919).—Formulas are given for calcg. the value of the extraordinary refractive index from observations on the sepn. of the two images of a line viewed through the drop of anisotropic liquid.

E. T. W.

**Fractional combustion (preferential catalytic combustion of the gases of mixtures).** W. D. BANCROFT. *Trans. Am. Electrochem. Soc.* 32, 465-74(1917).—The question which of 2 gases in a mixt. will burn the more rapidly and the influence of catalysts on the course of the phenomenon are discussed. At low temps. the former may be detd. by the nature of the catalyst. The influence of CuO, chamotte and borosilicate on the combustion of mixts. of H and CH<sub>4</sub> is considered. In the presence of CuO at 250° all the H and none of the CH<sub>4</sub> in a mixt. of these gases burns, while in the presence of chamotte the former burns more rapidly than the latter. In borosilicate bulbs at 300° to 400° CH<sub>4</sub>, C<sub>2</sub>H<sub>6</sub>, C<sub>2</sub>H<sub>4</sub> and C<sub>2</sub>H<sub>2</sub> burn more rapidly than either H or CO. When mixts. of CH<sub>4</sub>, O and H or CO are exploded by an elec. spark, the former burns much more rapidly than either the H or the CO. It is probable that charcoal would cause preferential burning of C<sub>2</sub>H<sub>4</sub> in a mixt. of this gas and H. It should be possible to obtain all intermediate stages from complete combustion of CH<sub>4</sub> to complete combustion of H in a mixt. of these gases by suitable selection of the catalyst. The sp. effect of a catalyst in influencing these preferential combustions probably disappears

at very high temps., because the reaction will occur so rapidly in the gas phase that the equil. reached will be that of the gas phase and not that of the catalyst.

H. JERMAIN CREIGHTON.

**The Hall-effect.** M. LA ROSA AND U. DE LUCA. *Nuovo cimento* 15, 89-99 (1918); *Science Abstracts* 21A, 509.—The nature of the secondary electrodes makes remarkable differences in the Hall-effect. Expts. are in progress to trace the cause of this.

E. H.

**Variable-pressure method for the measurement of viscosity.** E. C. BINGHAM. *Proc. Am. Soc. Testing Materials* 18, Pt. 2, 373-86 (1918).—B. sums up the difficulties encountered in measuring viscosities by the pendulum method and by the capillary-tube method, and points out the very marked advantages to be derived by modifying the present capillary tube viscosimeters so as to use variable pressures. The instrument described is accurate to a tenth of 1%, is easy to make and clean, and requires no special skill to operate. Cf. Bingham and Jackson, *C. A.* 11, 741 and Bingham, *C. A.* 8, 1525.

J. L. WILEY.

**Direct adiabatic calorimetry at high temperatures.** ALBERT PERRIER. *Lausanne. Arch. sci. phys. nat.* 46, 42-4 (1918).—The author discusses the difficulties and advantages of doing aneroid calorimetry adiabatically in electric furnaces, but makes no quantitative estimates. He considers non-uniform temps. and electrical leakages the main difficulties, but proposes to use only a pair of thermocouples to measure temp. The advantages claimed are: inexpensiveness, rapidity, the facts that the sample need not come in contact with water nor be protected from it, and the results are specific heats over short intervals.

W. P. WHITE.

**Determination of the temperature of the electrodes of the arc.** A. HAGENBACH AND K. LANGBEIN. *Arch. sci. phys. nat.* [5] 1, 48-54 (1919).—Ag, Cu, Fe, Ni and W were studied. The temp. was measured by a method of Lummer in which the relative brightness of 2 wave lengths is compared. This method is especially advantageous for surfaces which give far from black body radiation. A correction was made for the light emitted from the (gaseous) arc itself. The anode temps. are apparently the b. ps. of the respective metals. The cathodes are cooler, and so erratic that measurement was difficult. For feeble currents the anode temp. is lower, and by an amt. varying with the thermal cond. of the metal. The max. temps. observed were: Ag 2430° to 2450° (b. p. given by other observers from 2470° to 2680°); Fe, 2585° to 2605° (b. p. given from 2575° to 2730°); Ni, 2430° to 2450°; W, 4150° to 4250°. Al, Zn and Mg gave an arc based on an oxide layer or mass, with temp. far above the b. p. of the metal. In an atm. of N the anode temp. was the b. p.

W. P. WHITE.

**The conductivity of sea water.** H. R. RIVERS-MOORE. *Electrician* 82, 174-6 (1919).—The sample is placed in a glass tube having a pair of electrodes at either end. The inner electrode of each set is made of Cu gauze. Using a. c. the potential drop between the inner electrodes is balanced against that of a variable resistance in a Tinsley-Drysdale inductance and capacity bridge. (1) By audible frequencies, a sp. resistance given in tables is shown to be 26.5 ohms at 15°; (2) by radio-frequencies, varying from 30,000 to 100,000 p. s. the sp. resistance varied between the values 26 and 27 ohms, thus agreeing with previous method; (3) d. c. values of 26 and 26.2 ohms per cc. (15°) were obtained. Thus 26 to 27 ohms is the value for sea water near the mouth of an east coast estuary (Gt. Britain) for frequencies from 0 to 100,000 p. s. with c. d. from 0.01 to 15 milliamp. per (cm<sup>2</sup>). Open-sea samples gave at 15° a resistance of 24.3 to 24.7 ohms. The effectiveness of overcoming polarization is shown. It appears to be independent of the length of water column, being confined to electrode surface, and is usually of the order of 50 to 100 microfarads for electrodes of 2.7 (cm<sup>2</sup>). The capacity appears

to be independent of c. d. between 15 and  $\frac{1}{2}$  milliamp. per (cm<sup>2</sup>). Diagrams are given.

The electronic theory of valence and of chemical affinity. J. A. CROWTHER. *Scientia*, Nov. 1917; *Rev. Sci.* 56, 591-3(1918).—A brief review of at. structure and its chem. significance.  
G. L. WENDT.

Radioactive bismuth hydride. FRITZ PANETH. *Z. Elektrochem.* 24, 298-9(1918). P. claims to have produced  $\text{BiH}_3$  by the use of one of the radioactive isotopes of Bi. A strip of Mg sheet was exposed to Th emanation, which deposited upon it Th B and Th C; the former is an isotope of Pb, the later of Bi. The Mg was then dissolved in dil. HCl and the gas evolved carried off into the ionization chamber of an electroscope by a stream of N. This gas showed the characteristics of Th C only. That a hydride was present is proved by the fact that Cl did not produce this effect when used instead of HCl.  $\text{BiH}_3$  is a gas, quite stable at ordinary temp., but its stability decreases rapidly with rising temp., and it decomposes completely at a red heat; it can be condensed in the manner usually employed with emanations. A new kind of radioactive gas has here been produced.  
C. S. BRAININ.

The question of electrical charges smaller than the electron. FRITZ ZERNER. Univ. Vienna. *Physik. Z.* 17, 165-8(1916); cf. *C. A.* 9, 2030.—A reply to Fletcher (*C. A.* 10, 407). The calcn. of the elementary charge of  $4.78 \times 10^{-18}$  e. s. u. from data on Brownian movements is in error because the equation used by Fletcher has been shown to be incorrect by Schroedinger (*C. A.* 10, 299), Smoluchowski (*C. A.* 10, 416) and Konstantinowski (*C. A.* 10, 837). Calcn. of the charge from the law of resistance, however, demonstrates the existence of charges considerably less than the above value for the electron.  
G. L. WENDT.

The relation between the K X-ray series and the atomic numbers of the chemical elements. WM. DUANE AND KANG-FUH HU. Harvard Univ. *Phys. Rev.* 11, 488-9 (1918).—Continuation of the measurements of Blake and D. (*C. A.* 12, 649) to cover all the elements from Mn to Ce (*i. e.*, from  $N = 25$  to  $N = 58$ ) shows that the critical absorption frequencies for these elements follow the equation  $\nu = \nu_0 (N - 3.5)^2$ , where  $\nu_0$  is the Rydberg constant and  $N$  the at. number; but there is a small systematic variation from this law. The curve obtained is not linear but bends slightly upward. This frequency might be expected to be a characteristic of the chem. elements that increases by equal amts. in passing from one to the next since it is: (1) the highest frequency known to be characteristic of the element, (2) the frequency for which  $V_e = 1/3mv^2$  holds ( $1/3mv^2$  being the energy of the electron required to produce the K-series), (3) the critical ionization frequency, and (4) the critical absorption frequency. Though this is not the case, a linear relation is obtained for the velocity of the electron required to produce the K-radiation, *vis.*,  $v = v_0 (N - 1.5)$ , in which  $v_0 = 0.006780 \times$  the velocity of light. This is the critical velocity for all elements from those of highest frequency down to Mg. That this critical velocity should be a linear function of the at. number may indicate that the fundamental laws connecting X-radiation with other characteristics of the chem. elements represent velocity relations and not energy relations.

G. L. WENDT.

An X-ray fluorometer with a radio-luminescent standard. GUILLEMINOT, H. CHERON AND R. BIGNARD. *Compt. rend.* 167, 594-5(1918).—The previous app. (*C. A.* 12, 450) is improved by the substitution of standard luminescence from a screen of ZnS containing 0.05 mg. Ra, which gives a luminescence of the same color as the fluorescence of the Ba platinocyanide used to estimate the intensity of the X-rays and which does not lose more than 5% of its luminescence in the course of a year. A very weak standard luminescence is thus chosen because it suffers relatively little diminution with time while stronger preparations die down rapidly. The fluorometer is intended to be simple, accurate and practical.  
G. L. WENDT.

The influence of exposure to ultraviolet light on the emission of infra-red radiation by metals. HEINRICH HÖRIG. Stuttgart. *Physik. Z.* 17, 178-91(1916).—A strip of silver foil, heated by an elec. current and exposed during the heating and subsequent cooling to ultraviolet light from a quartz Hg-lamp, cools more rapidly by about 3% than a foil similarly heated and cooled in the dark. Temperatures were measured by a thermocouple. No such effect could be found with a Pt-Ir foil. The results are considered as preliminary. A discussion of modern expts. on the relation between radiant energy and the heat energy of materials is appended. G. L. WENDT.

Researches on chemiluminescence. J. LIFSCHITZ. Univ. Zurich. *Helvetica Chim. Acta* 1, 472-4(1918).—A brief and very preliminary statement that aromatic organo-Mg compds. in ether soln. react with  $O_2$ , air and  $N_2O$  with light emission.  $NO$ ,  $NO_2$ ,  $CO_2$  and  $H_2O$  do not cause luminescence. The stability of the etherate of the Mg compd. seems to det. the luminescence. Addition compds. with dimethylaniline show a similar but weaker luminescence. G. L. WENDT.

X-Ray apparatus. WM. D. COOLIDGE. Can. 187,781, Dec. 3, 1918.

#### 4. ELECTROCHEMISTRY.

COLIN G. FINK.

Electrochemistry in its human relations. F. J. TONE. *Trans. Am. Electrochem. Soc.* 35, preprint; *Chem. Met. Eng.* 20, 413-6; *Manufact. Record* 75, 97-8(1919).—Presidential address. A clear exposition of the present status of electrochem. industries and a forecast of the future activities and responsibilities. Among the problems considered are: (1) The world's food supply and the production of electrochem. fertilizer bases, air nitrates, potash, phosphates and cyanamide; (2) sanitation and sterilization by means of Cl and Cl products; Cl in org. chemistry and metallurgy; (3) elec. steel and ferro alloys; (4) sources of energy, coal and water power. A. BUTTS.

Review of the electrochemical and electrometallurgical industries of Switzerland. 1913-1918. ANON. *J. four. Elec.* 28, 33-4(1919). C. G. F.

Government ownership of water-powers and electrochemical industry. F. A. J. FITZGERALD. *Trans. Am. Electrochem. Soc.* 35, preprint; *Chem. Met. Eng.* 20, 30 (1919); *Manufact. Record* 75, 93-5(1919).—Examn. of the operation and ownership of water powers by the Hydro-Electric Commission of Ontario shows that "all evils associated with government activities in fields other than those for which governments are instituted among men, have developed and that the largest individual users of elec. energy, the electro-chem. industries, will be the most direct sufferers therefrom." C. G. F.

Power needs of United States nitrate plants. E. R. WELLES AND C. T. MITCHELL. *Elec. World* 73, 677-9(1919).—An outline of the nitrate plants at Sheffield, Ala., Plant No. 1, has the  $NH_4NO_3$  process. The generating equipment consists of 3 turbines and a steam-driven exciter of 4,000 boiler-h. p. and 5,000 kw. turbine capacity, or 1.2 kw. per boiler h. p. Plant No. 2 has the cyanamide process and 60,000 kw. capacity and 18,000 boiler-h. p., or 3.3 kw. per boiler-h. p. Two of the turbines (Plant No. 1) are rated at 1875 kva, the third at 1250 kva. Power is developed at 190 v., 60-cycle 6-phase, and most of it is converted into d. c. in three rotaries installed opposite the turbines. W. H. BOYNTON.

Unit-cost estimates for small hydro plants. ANON. *Elec. World* 73, 742(1919).—Data on the construction cost of a 180-kw. installation in Massachusetts. The total cost was about \$277 per kw. C. G. F.

**Power in chemico-metallurgical industries.** FLUSIN. *Eng. Mining J.* 107, 479(1919).—A table showing the consumption of elec. power and raw material in the principal French electrochem. and electrometallurgical industries. Data are given for P, Cl, NaOH, chlorates, perchlorates, SiC, corundum, CaC<sub>2</sub>, cyanamide, Na, Al, Fe, steel, ferro-alloys, Si-Mn, Si-Ca, and Si-Al.

LOUIS JORDAN.

**Features of Muscle Shoals station.** E. R. WELLES AND W. A. SHOUDY. *Elec. World* 73, 729-33(1919).—A detailed description of the government Nitrate Power Plant No. 2. It serves the largest single industrial plant load in the world. The final total generator capacity will approximate 120,000 kw. The elec. furnace load is an ideal one and because of its great uniformity it is expected that the load factor will be about 90%.

C. G. F.

**Commercial electric furnaces and their uses. II.** F. T. SNYDER. *Automot. Eng.* 4, 29-32(1919).—An increase of 300% in the world use of elec. furnaces, and a 700% increase in U. S. in last four yrs. shows desirability. Increase in output, speed, and economy are features claimed. Structural superiority is recognized in the following points: 1. Greater density and freedom from blow holes are obtained. 2. Tensile strength is 10,000 lbs. per sq. in. greater than that of open-hearth steel. 3. Elastic limit is 5 to 15% greater. 4. Working yield-point is 20 to 50% greater. Advantages are said to be due to absence of O<sub>2</sub>, N<sub>2</sub>, slag, etc. The material is subjected to a higher temp. Alloys (such as those of V, Cr, Si, and Mn) can be maintained more closely to a standard, and less of these valuable metals is required. Alloy additions can be made to the furnace directly. There is less liability to segregate, and less danger of overheating. It has a wider "safe heat" range. The adaptation to ferro-alloys has resulted in less loss of material by oxidation, because of neutral atm. and more perfect heat control. Elec. furnaces are rapidly superseding the crucible process. The 140 electric furnaces in U. S. are said to produce 8 times the tonnage of combined crucible steel plants. It is to be preferred for highest class work and for critical requirements. A description is given of the doorless Snyder furnace, with particular reference to long arc, simple construction, heat loss, operation and power consumption. The applications of the three types of this furnace are briefly stated. F. W. ZONS.

**A small oscillating fusion furnace for voltaic arc and heating of combustible compounds.** CH. BRÉZOL. *J. four élec.* 28, 30(1919).—In a small app. if the temp., approximates 1300-1400° it is still insufficient to obtain the necessary fluidity for casting steel, and also where the m. p. is higher (1500 to 1600). It is thus not possible in a small combustion furnace to attain the desired result. By the elec. arc, with which the highest temp. can be obtained, the insufficient heat of the combustion furnace is augmented. The combination of the two sources of heat is the principle on which this furnace rests. While high elec. energy has simplified the problem of heating furnaces, the cost is high. 900 kw.-hrs. per t. represents approx. the thermolec. energy for one 4-hr. operation. The mass is first heated to the usual temp., 1300 to 1400°, and in the last stages an arc is produced, which results in an economy of current, and installation. An oscillating furnace, with mineral-oil burners, is charged with 500 kg. scrap Fe. The top of furnace is pierced by two electrodes, from which the arc reflects down upon the metallic mass previously heated to 1200-1300°. F. W. ZONS.

**Improving the quality of gray iron by the electric furnace.** GEO. K. ELLIOTT. *Trans. Am. Electrochem. Soc.* 35, preprint.—Results of experiences of two years at the Lukenheimer Company, Cincinnati, O. The demand is growing for high quality gray Fe castings, such as used for high-pressure steam valves and cylinders for internal-combustion engines. Strong iron requires a high pouring temp. not provided for by the cupola, and for such the author recommends the duplex process. Melt from the cupola

is superheated in a basic-bottomed arc elec. furnace. Practically all of the S is removed by this treatment. Close regulation of C is attained by addition of scrap steel. Mn is not affected. A 25-min. period of heating in basic-lined furnace under proper reducing slag will generally reduce S from 0.100% to 0.030% or less. Also in *Iron Age* 103, 939-40(1919). C. H. ELDRIDGE.

**The design and operation of a small Kjellin furnace.** GEO. H. STANLEY AND W. BUCHANAN. *Met. Chem. Eng.* 18, 416-20(1918); cf. *C. A.* 12, 1729; 13, 283.—The problem of designing the furnace is dealt with. The methods used for calcg. the following factors are given: cond. of the secondary, energy required, magnetic field, open circuit current, power factor, pinch effect, primary coil, preheating of scrap, and frequency converter. Some operating tests and operating costs are given.

LOUIS JORDAN.

**Steel manufacture in electric furnaces.** H. L. HESS. *Raw Materials* 1, 105-7 (1919).—A general comparison of the duplex and cold melt methods of elec. steel is given. In the duplex system the molten steel, partially refined in the open-hearth, is charged into the elec. furnace to finish refining. The method calls for two types of equipment and specialists for both. The cold melt method is the more simple, especially for small units of 10 tons or less. The raw materials are charged into 6-7-ton Heroult elec. furnaces for refining. Careful temp. regulation is required. Total power input = 600-900 kw. per ton. Casting and rolling of ingots is also described.

C. H. ELDRIDGE.

**Electric furnace in steel making.** ANON. *Elect. Times*, Dec. 26, 1918, p. 383.—The author believes that too little publicity has accompanied the rapid advance of the elec. furnace. He reviews at length recent progress made. F. W. ZONS.

**Electric heat-treatment of gun forgings.** C. E. WRIGHT. *Iron Age* 103, 673-8 (1919).—A description of the plant of the Tioga Steel & Iron Company, Philadelphia, with special reference to the installation and operation of electric heat-treating furnaces. The furnaces can be used for the general run of large commercial forgings.

E. G. JARVIS.

**Principles of inductive heating with high-frequency currents.** E. F. NORTHRUP. Univ. Princeton. *Trans. Am. Electrochem. Soc.* 35, 88 pp.(preprint).—A very comprehensive presentation of the development of elec. heating with high-frequency currents and without interlinkage of an Fe magnetic circuit with an elec. circuit. In the first part of the paper the theory and the basic principles underlying this new method of elec. heating are discussed at length. By the mathematical treatment it is shown that there is no theoretical limitation to either the voltages which can be employed with safety or to the size of the units or the amount of power which can be used in this method of heating. It is also shown theoretically that in all cases where the high-frequency current is obtained from an alternator the supply lines can furnish power at practically unity power factor, and that the possibilities of obtaining high thermal efficiencies, rapid heating and elevated temps. are equal to or better than the results obtained in these respects by standard methods of elec. heating. The second part of the paper is devoted to applications of the theory. As a source of high-frequency current, the Tesla oscillatory current circuit has been employed. A diagrammatic representation is given of the arrangement used for the production of high-frequency currents by oscillatory discharge. The following subjects are discussed, the discussion being illustrated with numerous diagrams and photographs: the storage of elec. energy, the release of elec. potential energy, practical methods for reducing local surges, conditions suitable for the production of successive oscillatory discharges, power condensers, forms into which elec. potential energy may be transformed, power transformation

into heat in a single oscillatory-current circuit, circuits used for heating with high-tension single-phase and two-phase oscillatory discharge, and the principle of an arrangement called the "focus inductor." An artificially cooled inductor furnace is described and shown diagrammatically in cross-section. With this furnace, a temp. of 1800° or over can be maintained by applying a high-frequency e. m. f. (10,000 cycles or more) to the primary of the transformer, and the melt of ferrous metals or their alloys can be preserved free from C or undesired elements. It is believed that the most important application of high-frequency induction for heat treatment of materials at high temps. is the production of C-free melts, very rapid heating and excessively high temps. The quantities of materials which can be handled in this manner appear only to depend upon the power available with currents which exceed 10,000 cycles in frequency. With this new method of heating, batches of several kgs. of such materials as Pyrex glass, pure Ni and pure Fe have been rapidly melted in air and in vacuum, and Pt has recently been melted without the presence of C. The large expense of the condensers required, which are only active in the oscillatory current method from one-fifth to one-sixth of the time, the rather low power factor connected with this system and the high voltages necessary for generating the oscillations, would seem to limit this method of obtaining high-frequency currents to single power units of the order of magnitude of 100 kw. (Cf. C. A. 12, 242.)

H. JERMAIN CREIGHTON.

Production and distribution of electric-furnace products. ANON. *J. four élec.* 28, 25(1919).—A general discussion of the economics of elec.-furnace products, especially as regards the situation developed by the war and the future of these products in the light of resources in the different countries. In France, the majority of the electrochem. plants are complete units, having their own hydro-elec. installations. In Switzerland, a similar situation exists, with, however, most plants being lessors. In Italy, a situation similar to that in France and Switzerland, excepting a multitude of small elec. plants which rent current for the most part from the city distributing system. In Spain, as in France, but the carbide industry has not developed much. In England, excepting the aluminum industry, which used hydro-electric power, all other plants use current derived from steam-elec. central stations. In Sweden all the factories, both electrochem. and electrometallurgical, must obtain their current from large hydro-elec. plants established by the government. In Norway, in general, factories do not own hydro-elec. installations and they obtain current on long contracts from private stations. In U. S., most electrochem. plants have no water power; they obtain power from hydro-elec. concerns; this is especially the case at Niagara Falls. In other localities a sepn. between producer and consumer is preferred. The great elec. steel works are supplied by steam elec. stations. In Canada the situation is similar to that of the U. S., notably at Shawinigan Falls. All the current in the country is of hydro-elec. origin. From the point of view of international competition, the conditions in France and Switzerland are most favorable. Next come the Scandinavian countries, and lastly England and U. S., where cost of current is much higher than in Europe. F. W. ZONS.

The use of aluminum in the electrical industry. JULES GARÇON. *Bull. soc. encour. ind. nat.* 131, 155-80(1919).—An account of the increasing use of Al to replace Cu in elec. work for conductors and in elec. machines. Pure materials and careful control of the electrolytic bath in the production of Al to insure a pure metal are of great importance. The poor success attending the early use of Al conductors was due to the impurity of the Al and its lack of homogeneity. The usual impurities, Fe, Si, C, O and Na, should not together exceed 1.00 or 1.25% and the last two, especially Na, should be present only in traces. Al used for elec. purposes in England has usually not over 0.75% total impurities and an elec. cond. at 15° of 60% that of standard hard drawn Cu. Of Al alloys, only duralumin (Al-Cu-Mg) is important for elec. use.

In heat-treated condition it has a hardness and mechanical strength more than twice that of pure Al. The physical and mechanical, and the elec. properties of Al and Cu are compared.

LOUIS JORDAN.

Some remarks regarding the quality of calcium carbide. ANON. *Bull. soc. suisse acétylène*; *J. four. élec.* 28, 38-40(1919).—It is pointed out that the cost of  $\text{CaC}_2$  should be based upon the amt. of available  $\text{C}_2\text{H}_2$ . Carbides of various qualities are discussed. Those of superior quality often cause during decomposition an abnormal heating of the app., which produces sudden high pressures endangering the app., and which results in polymerization of part of the  $\text{C}_2\text{H}_2$  to tarry products,  $\text{C}_6\text{H}_6$ , and styrene, thus lowering the yield and obstructing the conduits and jets. It is suggested that the cause of this phenomenon is related to the phys. constitution of the  $\text{CaC}_2$  and to its porosity. In the case of a porous carbide, decompn. occurs not only on its surface but also in its interior, where the temp. rapidly rises to that necessary for the polymerization of  $\text{C}_2\text{H}_2$ . Since this polymerization is exothermic, more heat is furnished and a further quantity of the gas is polymerized, and so on. The extent to which abnormal heating and polymerization occur varies with the type of  $\text{C}_2\text{H}_2$  generator employed, and depends upon the rate at which the heat is dissipated. With carbides of poor quality, irregularities are produced in the generating app. H. J. CREIGHTON.

Gas warfare and the development of Edgewood Arsenal (chlorine). WM. H. WALKER. *Trans. Am. Electrochem. Soc.* 35, preprint; *Manufact. Record* 75, 95-6(1919).—An address. C. G. F.

Electrolytic process for the production of sodium permanganate from ferromanganese. R. E. WILSON AND W. G. HORSCH. *Trans. Am. Electrochem. Soc.* 35 (preprint).—A description of lab. expts., followed by semi-plant scale operation, wherein ferromanganese anodes were employed in a diaphragm cell containing a soln. of  $\text{Na}_2\text{CO}_3$  as the anolyte. It has been found that the current efficiency rises rapidly at first with increasing c. d., and then less rapidly after a c. d. of 7-9 amp./ $\text{dc}m^2$  has been attained. The current efficiency decreases rather rapidly with increase in temp., but this is somewhat offset by the decrease in voltage. The minimum energy consumption occurs at about  $30^\circ$ , although there is but slight variation between  $20^\circ$  and  $30^\circ$ . The commercial type of cell contains 2 compartments and has an effective diaphragm surface of  $6400\text{ cm}^2$ . The anode consists of 5 mechanically sound, cast ferro-Mn bars having the dimensions  $13 \times 4 \times 90\text{ cm}$ . With this cell a current efficiency of 35%, a cell v. of 7.0 and an energy consumption of 26.5 kw. hrs. per kg. of  $\text{NaMnO}_4$  have been obtained. If the concn. of permanganate in the anolyte is carried above 8%, the current efficiency drops and the anodes require to be changed more frequently. Runs at a c. d. of 13 amp./ $\text{dc}m^2$  demonstrate that the high yield per cell per day more than offsets the small increase in cost due to increased energy consumption, and that the cell may easily be kept cool at this c. d. It has been found preferable and entirely practical to operate at an av. temp. of about  $20^\circ$ . Details of design, costs and operating expenses, are given for a plant producing 0.5 ton of  $\text{NaMnO}_4$  per day. It has been estd. that  $\text{NaMnO}_4$  could be produced under war conditions at about 60 cents per lb.

H. JERMAIN CREIGHTON.

Electrolysis of fused sodium and potassium amides. L. WÖHLER AND FR. STANG-LUND. *Z. Elektrochem.* 24, 261-70(1918).— $\text{NaNH}_2$  is of technical importance in the synthesis of indigo dyes, and as an intermediate product in the prepn. of cyanides. The previously accepted m. p. (Titherley) was  $149-55^\circ$  for  $\text{NaNH}_2$  and  $270-2^\circ$  for  $\text{KNH}_2$ , while the authors find  $\text{NaNH}_2$  m.  $210^\circ$  and  $\text{KNH}_2$  m.  $338^\circ$ . The great reactive tendency of alkali amides makes them available for the prepn. of hydrazine, as made by Raschig.  $\text{N}_2\text{O}$  acts rapidly on  $\text{NaNH}_2$  at  $190^\circ$ .  $\text{Cl}_2$  under  $\text{C}_2\text{H}_2$  or  $\text{CCl}_4$  gives chlor-

amine and much  $\text{NCl}_3$ . Similarly,  $\text{I}_2$  gives black cryst.  $\text{NI}_3$  and  $\text{NH}_4\text{I}$ .  $\text{SO}_2$  acts on finely pulverized  $\text{NaNH}_2$  on warming, and on fused amide it gives  $\text{NH}_3$ ,  $\text{H}_2\text{S}$ , and polysulfide, but not hydrazine.  $\text{P}_2\text{O}_5$  on molten  $\text{NaNH}_2$  gives  $\text{PH}_3$ .  $\text{Hg}$  alone does not act on molten  $\text{NaNH}_2$ . Although Davy found  $\text{KNH}_2$  a non-conductor, nothing is known about the cond. of amides. Franklin and Kraus (*Ann.* 23, 277) found a soln. of  $\text{NaNH}_2$  (0.14%) in liquid  $\text{NH}_3$  to have 45 times the resistance of an equiv. aq. soln. of  $\text{NaOH}$ . At the m. p. the explosive hydrazide mentioned by Stolle (*J. prakt. Chem.* [2] 83, 200(1911)) is not formed.  $\text{NaNH}_2$  reacts catalytically on hydrazine, even at room temp. The  $\text{NH}_3$  from the initial product in turn breaks up:  $3\text{N}_2\text{H}_4 = 4\text{NH}_3 + \text{N}_2$ . A stream of inert gas satd. with hydrazine on passing over molten  $\text{NaNH}_2$  gave  $\text{NH}_3$ . The electrolysis of the melt was quantitatively studied and the investigation of the gases evolved showed the reaction  $6\text{NH}_2' + 6\oplus = \text{N}_2 + 4\text{NH}_3$ . No other products were found. The cond. and decompn. v. of the fused amides were detd. An app. was designed in which abs. pure Na and K amides were made, and their physical properties immediately investigated. By use of a cooling curve of the amides the m. p. was detd. more exactly than heretofore, with results above mentioned. No other stopping points were observed on the m.-p. curve above the m. p. The  $\text{NaNH}_2$  is white, cryst. and becomes colorless at the m. p. At higher temps. it assumes a greenish blue color, which becomes more intense with increasing temp.  $\text{KNH}_2$  is a waxy, white cryst. material, similar to  $\text{NaNH}_2$ . Both slightly attack glass. The temp. was measured by a Ag-Ni element, which is not acted upon chem. by the melt, and which shows a comparatively high e. m. f. at  $200^\circ$  (at  $40^\circ > 1$  millivolt). Analysis of the melt immediately after m.-p. detn. showed 40.93%  $\text{NH}_3$  (theoretical 41.1%). In the residue, however, Na = 60.00%, instead of theoretical 58.9%, due to the distg. flask being attacked in driving off  $\text{NH}_3$ . For  $\text{KNH}_2$ , similarly, the analysis showed 28.8%  $\text{NH}_3$  (theoretical 29.67%) and in the residue again a little more alkali (71.5%) instead of the calcd. 70.93%. The authors found (as also Dennis and Brown) that only Ni and Fe were sufficiently resistant at  $220^\circ$  for the study of anode gases. The  $\text{N}_2$  at the temp. investigated showed no measurable quantity of  $\text{H}_2$ , which verifies the assumption that the  $\text{NaNH}_2$  breaks up into Na and  $\text{NH}_2$  ions. The lack of other gases evolved contradicts suggested possibilities. A Cu voltameter gave results in accord with the equation  $6\text{NH}_2' + 6\oplus = 4\text{NH}_3 + \text{N}_2$ . The Na or K ion and the presence of  $\text{NH}_2$  was verified. No other ions were identified. In using alc. in the analysis of the amide by decompn. with  $\text{H}_2\text{O}$ , the authors claim to have improved on the method of Dennis and Brown (*Z. anorg. Chem.* 40, 93(1904)). The conds. of the amides were found for  $\text{NaNH}_2$ ,  $\chi_{210}^\circ = 0.593$  mhos,  $\text{KNH}_2$ ,  $\chi_{210}^\circ = 0.389$  mhos. The decompn. voltages were found to be  $\text{NaNH}_2$ ,  $E_{210}^\circ = 0.71$  v., with a temp. coeff.  $1.52 \times 10^{-3}$ , and for  $\text{KNH}_2$ ,  $E_{210}^\circ = 0.87$  v.

F. W. ZONS.

The function of barium sulfate in accumulators. O. SCARPA. *Elettrotecnica* 5, 371-2(1918); *Science Abstracts* 21B, 429.—Some large batteries of accumulators after 100 discharges showed only 40% of their initial capacity. This capacity should have remained const. for at least 200 discharges. S. attributes this loss to the physical properties of the  $\text{BaSO}_4$  mixed with the Pb oxides of the negative plate in order to make the mass more porous. The  $\text{BaSO}_4$  used was made in Italy. Its chem. properties were the same as the sulfate of German origin, which was used before the war, but its physical properties were different. Microscopic observations showed that the function of the  $\text{BaSO}_4$  was to prevent the cementing of the Pb particles to one another, transforming the soft Pb to hard Pb.

LOUIS JORDAN.

The chemistry of the action of the lead accumulator. CHARLES FÉRY. *Bull. soc. encour. ind. nat.* 431, 92-8(1919); cf. *C. A.* 12, 565.—Gladstone and Tribe regarded the active material of the + plate of a charged accumulator as  $\text{PbO}_2$  and that of the

negative plate as spongy Pb, both changing to  $\text{PbSO}_4$  on the discharge. Exptl. evidence is given to show that the + active material is not  $\text{PbO}_2$ , having neither its physical nor chemical properties, but is a higher oxide analyzing as  $\text{Pb}_2\text{O}_3$ . The discharge negative material is a sub-sulfate of Pb ( $\text{Pb}_2\text{SO}_4$ ). The mechanism of discharge at the negative plate is  $2\text{Pb} + \text{H}_2\text{SO}_4 = \text{Pb}_2\text{SO}_4 + \text{H}_2$ ; at the positive plate  $\text{PbO}_2 + \text{H}_2 = 2\text{PbO} + \text{H}_2\text{O}$ . The lower sulfate of Pb is very easily oxidized and in the air changes readily to the normal white  $\text{PbSO}_4$ .  
LOUIS JORDAN.

Weston normal cell comparisons. J. OBLATA. *Electrotechn. Lab., Tōkyō. Researches* 70, 1-11, May, 1918; *Science Abstracts* 21A, 388-9; cf. *C. A.* 12, 2478.—The first comparisons between the standards of e. m. f. of the Electrotechn. Lab. of Japan, of those of the National Physical Laboratory, England, and of the Bureau of Standards were made in 1914 by means of 4 cells of the English and 2 of the American institutions. In 1916 and 1917 other series of comparisons were made. It is highly probable that on all three occasions the standards of e. m. f. of the three institutions agreed within 1 part in 100,000.  
H. JERMAIN CREIGHTON.

Lead plating of shell interiors and boosters. A. G. REEVE. *Trans. Am. Electrochem. Soc.* 35, Preprint.—A detailed description of the app. and process utilized in Pb electroplating gas-shell interiors and boosters. After thorough cleaning, the shells were filled with a hot Cu "striking" soln. of the following compn.: Basic copper carbonate 225 g., NaCN 960 g., water 3.8 l. The Pb was deposited from fluoborate or fluosilicate bath. Cathode surface was five times anode surface and the quantity of bath small in proportion to the vol. of metal deposited. Thin, flat cast anodes had the widest part near the center and were 13 mm. wide at the top. A thin paddle, as wide as the shell opening would take, was used as stirrer. Rotating the anode and stirrer compensated for insufficient anode area. Current reached the spindles through babitt bearings set in woodwork and the spindles were divided into four batteries and connected in series with 6-v. plating current. The 13 spindles of each battery were connected in multiple. The fluosilicate bath contained: Pb 18.02%,  $\text{H}_2\text{SiF}_6$  14.14%,  $\text{H}_2\text{SiF}_6$  (free) 2.90%, and glue 0.4%. The thickness of plating was judged by dropping a 9 mm. steel ball through a perpendicular glass tube, 1.8 m. long, with the lower end resting upon the bottom of the shell. Pin holes were detected by means of the ferroxyl test. Boosters were plated as rotating cathodes on the shell-plating spindles. Light rejected shells were weighted in a manner similar to the lining of gas shells except that Ag was substituted for the Cu "strike."  
W. H. BOYNTON.

Physical phenomena accompanying cathodic deposition of metals (nickel). V. KORN-SCHUETTER AND E. VUILLEUMIER. *Z. Elektrochem.* 24, 300-21 (1918).—A Pt electrode  $20 \times 65 \times 0.1$  mm. and another  $0.05$  mm. thick is used in the observations recorded. The electrode is fastened at the upper end, and has a glass indicator which passes over a mm. scale, at the lower end. One side of the cathode (away from anode) is insulated with a copal varnish or vaseline. The authors call the app. a "contractometer." A soln. of  $\text{NiCl}_2$  is chosen, as Ni gives a most marked and characteristic effect. On electrolysis the cathode bends towards the anode (Ni). The extent of the bending was studied under various conditions. The bending increased with time. Cu, Ag and Fe solns. were used to show that the behavior was not characteristic of the app. but is related to the deposit. Of the solns. tried, that of  $\text{KAg}(\text{CN})_2$  showed least deflection, and  $\text{FeSO}_4$  soln. the greatest deflection for the same time. Increased concn. of  $\text{CH}_3\text{COOH}$  decreases the deflection, and HCl does so to greater extent. Small additions of  $\text{Fe}^{++}$  cause considerable increase while small amts. of  $\text{Zn}^{++}$  decrease the deflection. Indifferent salts ( $\text{Na}^+$ ,  $\text{Mg}^{++}$ , etc.) cause increased deflection as do also such org. substances as sugar, alc. and gelatin. In ammoniacal solns. high concn. results in smaller deflections. On cathodes only slightly deflected in these solns. the metal strips off.

A rapid deflection is characteristic at certain points, and occurs sooner when the c. d. is higher. In HCl soln. with increase of temp. an abrupt change takes place at  $0^\circ$  and at  $60^\circ$ , and on reversal of current a similar change is noted. The decompn. potential was found to be 1.7 v. The above results indicate two successive actions on the cathode, the fixing of a dispersed form of Ni film on the electrode, and then the formation of a layer which is associated with a surface contraction. The upper layer having more energy the two extreme conditions may be represented by  $(\text{Ni})_I$  and  $(\text{Ni})_{II}$ , in Nernst's formula  $P_I > P_{II}$ ,  $E_I = RT/2F \ln P_I/P > E_{II} = RT/2F \ln P_{II}/P$ . The difference corresponds to a difference in energy between the states of division of Ni. The results, therefore, appear characteristic of a condition of electrolysis, and not of Ni, although the latter shows it to a marked degree. The authors give a detailed explanation of the actions taking place at the cathode, which involves the chemical sepn. of  $\text{H}_2$  from discharged ions (atoms) and the physical escape of the gaseous  $\text{H}_2$ . In solns. which do not involve  $\text{H}_2$ , the bending is less. So also when the deposit is granular. The cathode is represented as a condenser on which a thin film of  $\text{H}_2$  deposits, which is pressed against the electrode by the electrical field. This film is thus between the electrode and ions in soln. As the film grows, the discharged ions are being deposited, and these closely attracted particles are sepd. by the growing film, the internal pressure of which is increasing. With the simultaneous sepn. of metal which is deposited in the film the latter, because of the pressure exerted, has the behavior of a viscous fluid. In the gaseous medium the Ni is condensed from ionic state as dispersed metal, and in the film also occurs a decrease in dispersion, which becomes apparent in the contraction of the deposit and consequent bending of the electrode. Curves representing the results are given. F. W. ZONS.

**Electroplating of iron from copper sulfate solution.** O. P. WARRS. *Trans. Am. Electrochem. Soc.* 35, Preprint.—W. discusses the use of As, Sb, Bi, Pb and Sn dipping solns. to insure good subsequent electroplating of Cu on Fe. Ni was not tried because of its proximity to Fe electrochemically. The As dip worked with HCl or  $\text{H}_2\text{SO}_4$  as solvent for  $\text{As}_2\text{O}_3$ , the Pb fluosilicate dip acted more slowly, while solns. of  $\text{Pb}(\text{NO}_3)_2$  and  $(\text{AcO})_2\text{Pb}$  acidified with  $\text{HNO}_3$  and  $\text{AcOH}$ , resp., caused the Cu plate to rub off easily, probably due to the cryst. Pb deposit. A very concd. soln. of  $\text{MgCl}_2$ , acid with HCl, as solvent for  $\text{SbCl}_3$  was used to prevent a black, spongy deposit of Sb on Fe. This dip requires a more strongly acid Cu-plating bath. Bi and Sn dips are unsatisfactory. Bi was successfully plated on Fe by aid of the As dip, but its brittleness precludes its general use in plating. The successful substitution of solns. of Sb and Pb for As and the application to plating on Fe with Bi show that the beneficial effect of the As dip is the result of coating the Fe with a metal whose potential in acid soln. is so near to that of Cu that it is possible to deposit a good Cu plate upon it, yet whose potential is not so far below that of Fe that it will deposit on Fe in powdery non-adherent form. W. H. BOYNTON.

**Building a cyanide copper-plating solution.** R. E. PETERS. *Metal Ind.* 17, 128-9 (1919).—After considerable exptl. work on Cu-plating solns. the following bath proved best:  $\text{Cu}(\text{CN})_2$ , 7 oz. (198.5 g.);  $\text{NaCN}$ , 9 oz. (255 g.); soda ash, 2 oz. (56.7 g.). Water 1 gal. (3.79 l.). Plating was conducted at  $77-82^\circ$ , using 3-4 v. at about 15 amp. per sq. ft. (1.62 amp. per sq. dm.). Daily the free cyanide was detd. and the necessary amts. of  $\text{Cu}(\text{CN})_2$  and  $\text{NaCN}$  to dissolve it were added. W. H. BOYNTON.

**Remarkable pitting in electroplating.** O. P. WARRS. *Trans. Am. Electrochem. Soc.* 35, Preprint.—After Pb plating for some time, heavy pitting developed which proved to be due to air dissolving in the electrolyte while not in use, and which was expelled as minute air bubbles on the work when the bath was heated by the passage

of the current. Pitting resulted only when evolution of gas from the work was extremely slow.

W. H. BOYNTON.

**Relative volatilities of refractory materials.** W. R. MOTT. *Trans. Am. Electrochem. Soc.* 34, Preprint.—A study of the order in which refractory materials volatilize in the elec. arc, and the distances at which their vapors condense from the arc. Ten arc methods for obtaining the relative volatilities of metals, carbides, oxides, nitrides, fluorides, chlorides and sulfides are suggested and partially developed. The following b. ps. have been estd. on a triple basis of reference to the curves with Fe for equal (atomic) amounts of materials, fractional distn. series and position of deposition at the negative crater; Fe satd. with C, 3,500°; SiO<sub>2</sub>, 3,500°; Pd, 3,600°; C, 3,700°; Al<sub>2</sub>O<sub>3</sub>, 3,700°; chromium carbide, 3,800°; vanadium carbide, 3,900°; Rh, 4,000°; Pt, 4,050°; uranium carbide, 4,100°; Ru, 4,150°; La<sub>2</sub>O<sub>3</sub>, 4,200°; titanium carbide, 4,300°; Yt<sub>2</sub>O<sub>3</sub>, 4,300°; columbium carbide, 4,300°; ZrO<sub>2</sub>, 4,300°; ThO<sub>2</sub>, 4,400°; Ir, 4,400°; Os, 4,450°; molybdenum carbide, 4,500°; yttrium carbide, 4,600°; thorium carbide, 5,000°; zirconium carbide, 5,100°; Ta (carbide?), 5,500°; and W (carbide?), 6,000°. The metals in this series were satd. with C, which would tend to raise the b. p. The volatility of the oxides investigated takes the following approx. order: K<sub>2</sub>O, Na<sub>2</sub>O, Li<sub>2</sub>O, V<sub>2</sub>O<sub>5</sub>, B<sub>2</sub>O<sub>3</sub>, BaO, SrO, MnO, FeO, CoO, NiO, Cr<sub>2</sub>O<sub>3</sub>, TiO<sub>2</sub>, V<sub>2</sub>O<sub>4</sub>, SiO<sub>2</sub>, CaO, MgO, (xCaO.ySiO<sub>2</sub>), (xBaO.yAl<sub>2</sub>O<sub>3</sub>), Al<sub>2</sub>O<sub>3</sub>, Ti<sub>2</sub>O<sub>3</sub>, V<sub>2</sub>O<sub>3</sub>, Er<sub>2</sub>O<sub>3</sub>, CeO<sub>2</sub>, Nd<sub>2</sub>O<sub>3</sub>, La<sub>2</sub>O<sub>3</sub>, BeO, Yt<sub>2</sub>O<sub>3</sub>, ZrO<sub>2</sub>, ThO<sub>2</sub>. BN sublimates at near 3000°. A number of theoretical considerations are advanced concerning the ratios of abs. b. ps. to m. ps., and upon a universal vapor-pressure curve applicable to all substances. The value of the ratio is 1.8 for all elements except the alkali metals for which the value is 3.3. In conclusion, a short bibliography of the subject is given.

H. JERMAIN CREIGHTON.

**A new vacuum tube for wireless.** IRVING LANGMUIR. *Wireless Age* 6, 15-6(1919).—Three circuits are illustrated and explained by the beat phenomenon. One shows the plate circuit of the vacuum tube coupled to the alternator, another has the cascade amplifier, and the third has the radio frequency alternator coupled directly to the antenna.

**Storage battery construction.** WM. MORRISON. *Can.* 189,797, Apr. 22, 1919. The battery comprizes a case, battery plates therein, cooperating means on said case and plates for supporting the plates and preventing sidewise movement thereof, a cover, means for securing the cover to the case, connectors secured to the plates and comprizing cooperating clamping parts engaging the upper and lower surfaces of the cover, means for clamping the parts together and means for sealing the parts between the cover and connectors.

**Storage-battery grid.** E. HANDLER. U. S. 1,293,419, Feb. 4. Structural features.

**Connectors for storage batteries.** WM. MORRISON. *Can.* 189,796, Apr. 22, 1919. The connector comprizes a plate member having a cavity therein, a wedge member having a wedge portion fitting into the cavity, means for sealing the point between the wedge member and the top of the plate member, a wedging member within said wedge portion and a headed screw bolt extending through the wedge member and

into screw threaded engagement with the wedging member and means for sealing the point between the head of the bolt and the wedge member.

**Storage battery electrodes and filling mass therefor.** WM. MORRISON. Can. 189,798, Apr. 22, 1919.  $\text{H}_2\text{SO}_4$  and  $\text{PbO}$  are mixed under conditions to initiate an energetic reaction and to produce a non-acid stable filling mass which is transferred to a grid or support and subjected to sufficient pressure to initiate the setting of the mass and the plate is formed electrolytically before the filling mass has attained its maximum hardness. Cf. C. A. 13, 94.

**Arc-welding electrode.** C. V. ELLIOTT. U. S. 1,294,250, Feb. 11. Arc-welding ferrous metal electrodes are coated with a very thin layer of  $\text{Ca(OH)}_2$  by dipping them in milk of lime and drying. Electrodes thus prepd. operate with a smooth-flowing quiet arc and deposit welding metal evenly without the disadvantage of including melted flux within the deposited metal such as may occur when a relatively thick sheath of fluxing material is used on the electrode. Similar results are secured by using, instead of  $\text{Ca(OH)}_2$ , other hydroxides, fluorides, chlorides, carbonates, silicates or sulfates of Ca, Ba, Sr, Mg, Na, K or Li.

**Manganese peroxide for use as a depolarizer.** M. L. KAPLAN. U. S. 1,293,461, Feb. 4. Artificial  $\text{MnO}_2$  suitable for use as a depolarizing material in dry-cell batteries is prepd. in the following manner:  $\text{MnCO}_3$  heated to  $300^\circ$  is exposed to the action of hot air for several hrs. to obtain a product containing over 70%  $\text{MnO}_2$ . After cooling, this product is moistened with 10-20%  $\text{HNO}_3$  and the moist mixt. is gradually heated first to drive off  $\text{H}_2\text{O}$  and excess acid and then to decompose the  $\text{Mn(NO}_3)_2$  formed without decomposing other nitrates present as impurities which remain undecomposed unless heated to higher temps. than that required to decompose  $\text{Mn(NO}_3)_2$ . The  $\text{MnO}_2$  is freed from nitrates of metals other than Mn by treatment with  $\text{H}_2\text{O}$  and there is thus obtained a residue, which, after drying, is a fine, dense, gray-colored powder closely resembling the powdered mineral  $\text{MnO}_2$  but superior to the latter in purity and in depolarizing action. Oxides of N may be mixed with the air used for treating the  $\text{MnCO}_3$  to shorten the time and reduce the temp. required.

**Depolarizing material for dry-cell batteries.** M. L. KAPLAN. U. S. 1,293,462, Feb. 4. The pat. relates to the manuf. of an efficient depolarizing material from  $\text{MnO}_2$  compds. containing various basic impurities such as are known as "recovered manganese." The material is treated with sufficient  $\text{HNO}_3$  to form nitrates of all the metals present and the mass thus obtained is treated in the same manner as the nitrate mixt. in the process of U. S. pat. 1,293,461 (*supra*). The conducting material to be used with the depolarizer may be incorporated before the treatment with  $\text{HNO}_3$ .

**Depolarizer material from natural manganese dioxide.** A. A. WELLS. U. S. 1,293,272, Feb. 4. Natural  $\text{MnO}_2$  such as a medium or good grade of pyrolusite is mixed with charcoal or coke and the mixt. is heated in an elec. furnace to form  $\text{Mn}_2\text{C}$ . The latter is then reacted upon by  $\text{H}_2\text{O}$  to form  $(\text{MnO}_2\text{H}_2)_2$  in light flocculent form, which is sepd. from Fe compds. and other impurities by flotation and washing with a stream of  $\text{H}_2\text{O}$ . The hydrate thus sepd. is then oxidized by the action of ozonized air or by heating to  $150$ - $250^\circ$  in a current of moist air, forming  $\text{Mn}_2\text{O}_8$ , which is suitable for use with graphite as a depolarizing material in dry batteries.

**Electrolytic tungsten.** F. G. KEYES. U. S. 1,293,117, Feb. 4. Pure metallic W is obtained by dissolving W in boric acid at a temp. of  $1200$ - $1400^\circ$  and electrolyzing the soln. thus formed.

**Metals for filament manufacture.** A. PACZ. Can. 188,740, Feb. 18, 1919. Filaments substantially free from offsetting after continued use and containing no crystn.-retarding material attributable to the addition of material for this purpose during the

prepn. are made by mixing salts having substantially the same chem. compn. but differing in their mode of prepn. so that they have different mol. structures, agglomerating the mixt. and mechanically working the body so produced.

**Treating gases and vapors electrically.** W. T. HOOFNAGLE. Can. 189,634, Apr. 15, 1919. A field having intermittent electrical discharges of short duration and high current density is maintained between electrodes in a closed chamber and gases to be treated are passed through the field at a pressure below atm. and at a speed proportioned to the periodicity of the discharges. App. is specified.

**Uniting tungsten filaments with nickel wires.** M. A. HOYT. U. S. 1,293,781, Feb. 11. W filaments of incandescent elec. lamps are united with Ni leading-in wires by pressing the filament and wire together and heating the joint by passing an elec. current through it.

**Tungsten filaments.** F. G. KEYS. U. S. 1,293,116, Feb. 4. W filaments for incandescent lamps are prepd. by depositing W electrolytically upon a fine W wire and hot-drawing the wire through dies of W-Fe-C alloy lubricated with powdered talc.

**Electric arc furnace for metallurgical uses.** W. E. MOORE. U. S. 1,293,164, Feb. 4.

**Electric arc furnace adapted for heating retorts or cupels.** I. RENNERFELT. U. S. 1,294,830, Feb. 18.

**Electric arc furnace adapted for melting brass.** F. VON SCHLUBERL and C. B. FLETCHER. U. S. 1,294,837, Feb. 18.

**Hooks for electroplating.** O. RONDZL. Can. 189,817, Apr. 22, 1919. Structural features.

**Selenium bridges.** F. C. BROWN. Can. 189,334, Mar. 25, 1919. A bridge is made from a Se crystal or crystals formed by freeing Se from occluded gases, vaporizing in vacuum and causing the deposition of crystals from the Se vapor. The crystals may be made to absorb one or more gases.

**Purifying aluminous materials.** O. HUTCHINS. Can. 190,031, Apr. 29, 1919. Aluminous material is fused with C insufficient in amt. to reduce all the  $Fe_2O_3$ ,  $TiO_2$  and  $SiO_2$  contained therein, the material is sepd. from the reduced impurities and again fused with sufficient C to produce an abrasive containing at least 97% of  $Al_2O_3$ .

## 6. INORGANIC CHEMISTRY.

H. I. SCHLESINGER.

**Inorganic complexes.** JOSE R. MOURELO. *Rev. sci.* 57, 65-72(1919).—A review and appreciation of the theories of Werner regarding the formation of complexes, such as auxiliary valence, the coördination number and the explanation of isomerism of hydration, of stereoisomerism, and of metamerism of ionization. The author admits the rigidity of Werner's system, but otherwise is in hearty accord. G. L. CLARK.

**Transformation and oxidation of chromic hydroxide in alkaline solution.** F. BOURION and A. SENECHAL. *Compt. rend.* 168, 59-62(1919); cf. C. A. 8, 1069.—Alk. solns. of  $Cr(OH)_3$  undergo a transformation with time by which they lose chem. activity, particularly their reducing power toward  $H_2O_2$ . The rate of change is more rapid as the concn. of Cr increases and the concn. of NaOH decreases. A soln. of 0.938 g.  $Cr_2O_3$  and 0.294 mol. NaOH per l. when stirred for 2 min. with 5-fold the calcd. quantity of  $H_2O_2$  was 81.8% oxidized when the alk. chromite had stood 5 min., 54.4% after 30 min., 12.7% after 6 hrs., and 2.6% after 51.5 hrs. A. R. M.

**Solubility of cupric hydroxide in sodium and potassium hydroxides of sufficient concentration.** E. JUSTIN-MUELLER. *Compt. rend.* 167, 779-80(1918).—NaOH (d. 1.345-1.370) and KOH (d. 1.453-1.498) dissolve 0.78 g.  $\text{Cu}(\text{OH})_2$  per 100 cc. The solns. are perfectly stable and do not change upon heating even after large diln. Soln. is incomplete in less concd. lyes or if the proportion of Cu is increased.

A. R. MIDDLETON.

**The cycle of oxidation of nitric oxide in presence of water.** A. SANFOURCHE. *Compt. rend.* 168, 401-4(1919).—Mixts. of NO with large excess of air ( $\text{NO}:\text{O}_2 = 1:1$ ) with time of contact sufficient to transform 95% of the NO to  $\text{N}_2\text{O}_4$  at  $50^\circ$  were found to contain about 92% of the NO as  $\text{N}_2\text{O}_3$  and 8% as  $\text{N}_2\text{O}_4$ . In contact with mixts. of water and  $\text{HNO}_3$  these proportions were scarcely changed until the acid reached a concn. of 47.5% (33.5° Bé.) when 69% was transformed to  $\text{N}_2\text{O}_3$  and 31% to  $\text{N}_2\text{O}_4$ . With 62% acid (40° Bé.) about the same proportions were transformed but with 94% acid (48° Bé.) 2.8% was transformed to  $\text{N}_2\text{O}_3$  and 97.2% to  $\text{N}_2\text{O}_4$ . S. concludes that  $\text{N}_2\text{O}_3$  is the chief intermediate product, being decompd. according to  $3\text{N}_2\text{O}_3 + \text{H}_2\text{O} = 2\text{HNO}_3 + 4\text{NO}$ , involving a cycle in which  $\frac{2}{3}$  of the NO is periodically regenerated. The reversible oxidation of  $\text{N}_2\text{O}_3$  by  $\text{HNO}_3$  according to  $\text{N}_2\text{O}_3 + 2\text{HNO}_3 \rightleftharpoons 2\text{N}_2\text{O}_4 + \text{H}_2\text{O}$  and  $\text{N}_2\text{O}_4 + \text{H}_2\text{O} \rightleftharpoons \text{HNO}_3 + \text{HNO}_2$  conditions an equil. shown by these expts. to be reached at approx. 50% acid. In industrial practice the tower acid or that recovered in the columns varies little from this concn.

A. R. MIDDLETON.

**Constitution of nitrous vapors.** P. JOLIBOIS AND A. SANFOURCHE. *Compt. rend.* 168, 235-7(1919).—Mixts. of NO and air dried by a long column of  $\text{CaCl}_2$  were caused to circulate in an app. which permitted measurement of the time of contact; the proportion of  $\text{N}_2\text{O}_3$  to  $\text{NO}_2$  was detd. within 0.5% by bubbling the gas through concd.  $\text{H}_2\text{SO}_4$ , by which  $\text{N}_2\text{O}_3$  is transformed quant. to nitrosyl bisulfate while  $\text{NO}_2$  gives equal mols. of this and  $\text{HNO}_3$ ; NO is not absorbed. N was then detd. by nitrometer and a titration with  $\text{KMnO}_4$  completed the necessary data. Results show that with NO and air in proportion to form  $\text{N}_2\text{O}_3$  combination is instantaneous; after 100 secs. no  $\text{NO}_2$  formed, showing that  $\text{N}_2\text{O}_3$  does not dissociate under these conditions. With proportions to form  $\text{NO}_2$  combination to  $\text{N}_2\text{O}_3$  takes place at once; after 1 sec. no  $\text{NO}_2$  was detectable; after 20 sec. 34%, after 37 sec. 68%, after 100 sec. 92% was transformed to  $\text{NO}_2$ . With air in greater proportion or with pure  $\text{O}_2$  the times of transformation to  $\text{NO}_2$  were of the same order and, however prolonged the contact oxidation, did not proceed beyond  $\text{NO}_2$ . The gas mixt. was also passed through a quartz tube, the time of passage being 2 sec.; up to  $400^\circ$  the equil. tends toward  $\text{N}_2\text{O}_3$  with partial destruction of the nitrous vapors.

A. R. MIDDLETON.

**Carburization of ceric oxide.** A. DAMIENS. *Ann. chim.* 10, 330-52(1918); cf. C. A. 13, 542.—This work was undertaken to clear up various anomalies and contradictions in the literature. The following conclusions are reached: The oxycarbide of Sterba (*Compt. rend.* 134, 1056(1902)) to which he assigned the formula  $\text{CeC}_{2.2}\text{CeO}$ , is not a definite compd. The formation of  $\text{CeC}_2$  in the elec. furnace is preceded by the reactions  $2\text{CeO}_2 + \text{C} = \text{Ce}_2\text{O}_3 + \text{CO}$  and  $\text{Ce}_2\text{O}_3 + 9\text{C} = 2\text{CeC}_2 + 3\text{CO}$ . The intermediate products obtained by various investigators were solid solns. of  $\text{CeC}_2$  in  $\text{Ce}_2\text{O}_3$ .  $\text{CeC}_2$  can decomp. into  $\text{CeC}_2$  and graphite, which explains the invariable occurrence of graphite in incompletely reduced Ce oxides and the invariable failure to prep. carbides of Ce containing less than 4% of graphite.  $\text{CeC}_2$  is readily attacked by water with formation of  $\text{C}_2\text{H}_2$ , but when dissolved in small amts. in  $\text{Ce}_2\text{O}_3$  it is protected and only acids which dissolve the oxide can produce its complete decompn.

**Potassium ammonosodiate, potassium ammonolithiate, rubidium ammonosodiate, and rubidium ammonolithiate.** E. C. FRANKLIN. *J. Phys. Chem.* 23, 36-53(1919);

cf. C. A. 9, 2851.—*Dipotassium ammonosodiate*,  $\text{NaKNH}_2 \cdot 2\text{NH}_3$  or  $\text{NaNH}_2 \cdot 2\text{KNH}_2$  or  $[\text{Na}(\text{NH}_2)_2]\text{K}$ , was prepd. in liquid  $\text{NH}_3$  by (1) action of  $\text{KNH}_2$  soln. on  $\text{NaNH}_2$ ; (2) addn. of  $\text{NaI}$  to excess of  $\text{KNH}_2$  soln.; (3) allowing a soln. of  $\text{Na}$  and excess of  $\text{KNH}_2$  to stand in contact with a small amt. of  $\text{Pt}$  black. The salt forms well developed crystals which which loose no  $\text{NH}_3$  at  $100^\circ$  in vacuum. It is decompd. by liquid- $\text{NH}_3$  solns. of acids and vigorously by water. *Rubidium ammonosodiate*,  $\text{NaNHRb} \cdot \text{NH}_3$  or  $\text{NaNH}_2 \cdot \text{RbNH}$  or  $[\text{Na}(\text{NH}_2)_2]\text{Rb}$ , was prepd. by the preceding method (3). It is similar in appearance and properties to the  $\text{K}$  compd. By evapn. to crystn. of the mother liquors which contained a large excess of  $\text{RbNH}_2$ , a product of different appearance from the mono- $\text{Rb}$  salt and distinctly more sol. was obtained. Analysis approxd.  $[\text{Na}(\text{NH}_2)_2] \cdot \text{Rb}$ . *Dipotassium ammonolithiate*,  $[\text{Li}(\text{NH}_2)_2]\text{K}$ , was obtained pure by methods (1) and (3). *Rubidium ammonolithiate*,  $[\text{Li}(\text{NH}_2)_2]\text{Rb}$ , was prepd. by method (3). All these salts are rapidly decompd. by water and by liquid- $\text{NH}_3$  solns. of acids. Attempts to obtain a definite compd. of  $\text{RbNH}_2$  and  $\text{KNH}_2$  were unsuccessful; cryst. products were obtained which appeared to be isomorphous mixts. of the 2 amides.

Subacetate and subsulfate of lead. H. G. DENHAM. *J. Chem. Soc.* 115, 109-13 (1919); cf. C. A. 11, 1799; 12, 1951.—Preliminary expts. with  $\text{AcOMe}$  and  $\text{AcOEt}$  showed that at  $310^\circ$  the subacetate decomps. completely to  $\text{Pb}$  while at  $\text{AcOEt}$  much lower the reaction was too slow. Acetic anhydride gave good results. The app. and procedure were the same as previously employed. About 8 cc. of anhydride was distd. through the bulbs at  $195^\circ$ , the distn. lasting about 80-90 min. The oven was cooled to  $180^\circ$ , the app. was exhausted and the bulbs were sealed off for analysis. The subacetate usually contained 1-3% water, due probably to traces of  $\text{AcOH}$  in the anhydride. The ratio  $\text{Pb}:\text{C}_2\text{H}_3\text{O}_2$  agreed with theory. Some samples free from moisture were prepd. and showed no difference in soly. and properties from the hydrated samples. In 7 expts. with anhydride containing  $\text{AcOH}$  the av. was  $\text{Pb} = 75.8$ ;  $\text{C}_2\text{H}_3\text{O}_2 = 21.5$ .  $(\text{AcOPb})_2 \cdot \text{H}_2\text{O}$  contains  $\text{Pb} = 75.3\%$  and the products may have been this hydrate mixed with anhydrous salt. The cond. was compared with that of dehydrated normal acetate at  $25^\circ$  in abs.  $\text{EtOH}$ . The resistance of the  $\text{EtOH}$  was 90,000 ohms, satd. soln. of normal acetate 4100 ohms, of subacetate 6100, 6400, 6000 ohms. The behavior of the normal and of the subsalt when slowly heated *in vacuo* was entirely different. The subacetate, like the other sub-salts, is decompd. by acid into metal and normal salt. It is bluish gray. The subsulfate was prepd. by distn. of  $\text{Me}_2\text{SO}_4$  through the suboxide at  $280^\circ$  for 75 min. It is dark gray. Cond. expts. at  $18^\circ$  gave water 27,000 ohms, satd.  $\text{PbSO}_4$  3030 ohms, subsulfate 3100 ohms in air, 3200 ohms *in vacuo*. The small difference indicates decompn. into  $\text{Pb}$  and  $\text{PbSO}_4$  but no change in appearance of the residue was detectable. In  $\text{EtOH}$  resistance was 90,000 ohms, satd.  $\text{PbSO}_4$  93,000 ohms, satd. subsulfate 75,000 ohms. The subsulfate was heated  $120^\circ$  above the m. p. of  $\text{Pb}$  for 4 hrs.; no change whatever could be detected in the appearance of the salt and the microscope showed entire absence of anything in the nature of minute globules of  $\text{Pb}$ .

Synthesis of ammonia at high temperatures. III. E. B. MAXTED. *J. Chem. Soc.* 115, 113-9 (1919); cf. C. A. 12, 2235.—The present paper deals with the formation of  $\text{NH}_3$  in an arc of larger size and more usual character than those previously employed. For the production of the arc 50-cycle a. c. at a max. p. d. of 375 v. was transformed by an oil-immersed static transformer having a step-up factor of 31.5. A sketch of the app. is given. It was found possible to obtain appreciable quantities of  $\text{NH}_3$  by almost any method by which mixts. of  $\text{N}_2$  and  $\text{H}_2$  were brought into the arc flame with subsequent rapid cooling, but for this preliminary study of max. percentage formed as distinguished from max. elec. efficiency, it was found preferable to let the arc

burn freely in the gas mixt. and to draw off samples by means of a quartz capillary placed close to the arc. The vol. concn. of  $\text{NH}_3$  increased with rate of flow to a max.; 0.49% at 0.5 liter/hr., 1.04% at 1.14 l./hr., 0.56% at 2.1 l./hr., 0.32% at 7.5 l./hr. For this series 0.04 amp. at 3250 v. was taken for arc formation. Additional evidence is presented that  $\text{NH}_3$  is formed by direct combination and not by reduction of NO due to  $\text{O}_2$  in the  $\text{N}_2$  used. The same vol. of  $\text{N}_2$  and  $\text{H}_2$  mixt. was passed repeatedly through a small arc,  $\text{NH}_3$  being absorbed by  $\text{H}_2\text{SO}_4$  at each passage. The data show practically uniform percentage of  $\text{NH}_3$  formed at each passage, even after more than 30 passages. M. believes this demonstrates beyond doubt the direct nature of the synthesis.

**Interaction of stannous and arsenious chlorides.** R. C. DURRANT. *J. Chem. Soc.* 115, 134-43 (1919).—D. concludes from his own expts. confirming Bettendorf (*Ann.* 144, 110 (1867)) that the first deposit of As is of the yellow type but that this soon becomes brown or gray unless certain conditions not yet ascertained are fulfilled. The anhydrous chlorides do not react, but introduction of a trace of water causes much reaction. A study of the reaction velocity showed that it is accelerated chiefly by increase of the HCl concn., next by that of  $\text{AsCl}_3$  and least by that of  $\text{SnCl}_4$ .  $\text{AsCl}_3$  acts as a second power and  $\text{SnCl}_4$  to the square root of its concn. Chloride ions proceed partly from  $\text{AsCl}_3$  and partly from HCl and act as a first power. The data obtained are best accounted for by the hypothesis that the reaction is between chloride ions, arsenious ions and a complex,  $\text{H}_2\text{SnCl}_4$ . The reaction is of the first order and the slowest reactant is the complex. Essentially the reaction consists in the disintegration of the complex by circumambient ions.

A. R. MIDDLETON.

**Thiocyanates of gold and free thiocyanogen.** NIELS BJERRUM AND A. KIRSCHNER. *Kgl. Danske Videnskabernes Selskab.* [8] V, No. 1, 76 pp. (1918).— $\text{KAu}(\text{SCN})_4$ , prepd. according to Cleve (*J. prakt. Chem.* 94, 14 (1865)) had always too high Au (42.27-42.44; calcd. 42.08%) and too low K (8.02-8.16; calcd. 8.34). Similarly prepd. new salts,  $\text{NH}_4\text{Au}(\text{SCN})_4$ , orange, and  $\text{NaAu}(\text{SCN})_4$ , red cryst., approxd. more closely to the formulas. For the values of the sol. product consts. were calcd., K salt,  $6 \cdot 10^{-8}$  in an ion-normality of 1.4; N salt,  $5 \cdot 10^{-4}$  in 2.2 ion normal soln. and  $4 \cdot 10^{-4}$  in 0.6 normal soln. The soly. of the  $\text{NH}_4$  salt is about that of the K salt; that of the Ba salt (not analyzed) approx. that of the Na salt. The free acid  $\text{HAu}(\text{SCN})_4 \cdot 2\text{H}_2\text{O}$  was obtained by extg. with  $\text{Et}_2\text{O}$  a mixt. of 30 g.  $\text{NaSCN}$ , 200 cc. 1.5 M  $\text{H}_2\text{SO}_4$  and 100 cc. 10%  $\text{HAuCl}_4$ . 150 cc. ext. was dried with 15 g. anhydrous  $\text{Na}_2\text{SO}_4$  for 10 min. and evapd. *in vacuo*. Fine, dark red crystals were formed, stable in air but losing more than water over  $\text{H}_2\text{SO}_4$ . Aurous salts were prepd. by reducing acid solns. of auric salts with  $\text{Na}_2\text{SO}_3$  at ord. temp., extg. the colorless soln. with  $\text{Et}_2\text{O}$  and neutralizing the ext. with  $\text{KHCO}_3$  or  $\text{NH}_3$ . Both salts were pure white and analysis agreed closely with  $\text{KAu}(\text{SCN})_3$  and  $\text{NH}_4\text{Au}(\text{SCN})_3$ . Both are slowly decompd. by water. Cleve's method of prepn. by auto reduction gave impure straw-colored products. Upon extn. of acid solns. of these salts with  $\text{Et}_2\text{O}$  and washing the ext. with acid water to faint color of the latter with ferric salt, the  $\text{Et}_2\text{O}$  contained 2 SCN groups per Au atom, indicating  $\text{HAu}(\text{SCN})_2$  in soln. Evapn. of the  $\text{Et}_2\text{O}$  gave a reddish oil, the color of which deepened gradually, indicating a content of auric compd. The oil partially dissolved in  $\text{Et}_2\text{O}$  leaving a white, amorphous residue; both oil and residue dissolved in  $\text{NH}_3$ , giving pure, white  $\text{NH}_4\text{Au}(\text{SCN})_3$ . Upon dehydrating the  $\text{Et}_2\text{O}$  soln. of  $\text{HAu}(\text{SCN})_2$  with  $\text{Na}_2\text{SO}_4$  and satg. with  $\text{NH}_3$  Cleve's aminoaurorothiocyanate,  $\text{AuNH}_2\text{SCN}$ , was obtained in good yield. It is snow-white, darkens under exposure to light and is decompd. by water. It is easily sol. in  $\text{EtOH}$  containing  $\text{NH}_4\text{SCN}$ . The compn. and complexity of the  $\text{Au}(\text{SCN})_3$  ion was detd. by the method of Bodländer (*Z. phys. Chem.* 39, 607; *Z. anorg. Chem.*

31, 458(1902)) by measuring the p. d. between Au electrodes in two aurothiocyanate solns. in which the same  $[\text{SCN}^-]$  and different  $[\text{Au}^+]$  gives from the p. d. the no. of Au atoms in the complex and the same  $[\text{Au}^+]$  and different  $[\text{SCN}^-]$  gives from the p. d. the no. of  $\text{SCN}^-$  in the complex. For  $\text{Au}_m(\text{SCN}^-)_n$ ,  $n/m = E/1.983 \cdot 10^{-4} \cdot T \cdot \log(C_1/C_2)$ , where  $C_1$  and  $C_2$  are the concns. of  $\text{SCN}^-$  in solns. of the same  $[\text{Au}^+]$ ; and  $m = (1.983 \cdot 10^{-4} \cdot T/E) \cdot \log(C_1/C_2)$  in which  $C_1$  and  $C_2$  are concns. of  $\text{Au}^+$  in solns. containing the same  $[\text{SCN}^-]$ . The mean of the value found was  $m = 1.02$ ;  $n:m = 1.99$ , clearly indicating  $\text{Au}(\text{SCN})_2$  in soln. In the solns. used  $[\text{SCN}^-]$  varied from 0.1 to 1 molar;  $[\text{Au}]$  1-40 decimillimolar; acid, 0.0003-1 molar. It is concluded that the detn. by Abegg and Campbell (*Z. Elektrochem.* 13, 440(1907)) of the normal potential of gold-auroion is merely the oxidation potential of  $\text{HNO}_3$  since platinized Pt electrodes gave approx. the same values as their gold electrodes. The normal potential of  $\text{Au}-\text{Au}(\text{SCN})_2$  was detd. at  $20^\circ$  against a 0.1 N calomel electrode from  $E' = {}_0E + \frac{RT}{F} \ln \frac{[\text{Au}(\text{SCN}^-)_2]}{[\text{SCN}^-]}$ , (Henderson, *Z. phys. Chem.* 59, 118; 63, 325(1907-8)), where  $E'$  is the measured e. m. f. + 0.016 diffusion potential. For  ${}_0E$  was found +0.352 which, plus 0.337, gives for the potential toward N hydrogen,  ${}_0E_h = +0.689$  v. From this and Bodländer's (*Ber.* 36, 3933(1903)) value for the potential  $\text{Au}-\text{Au}(\text{CN})_2 = -0.611$  v., was calcd. the relative complexity (stability) of the complex ions from  ${}_0E' - {}_0E = (RT/F) \ln(K'/K)$ , where  ${}_0E$  and  ${}_0E'$  are the two normal potentials and  $K = [\text{Au}(\text{SCN}^-)_2]/[\text{Au}^+] \cdot [\text{SCN}^-]^2$  and  $K' = [\text{Au}(\text{CN}^-)_2]/[\text{Au}^+] \cdot [\text{CN}^-]^2$ .  $K'/K = 10^{\frac{0.689 - 0.611}{0.058}} = 10^{22.4}$ . Neglecting possible formation of  $\text{AuC}(\text{N})(\text{SCN}^-)$ ,  $K'/K = \frac{[\text{Au}(\text{CN}^-)_2] \cdot [\text{SCN}^-]_2}{[\text{Au}(\text{SCN}^-)_2] \cdot [\text{CN}^-]_2} = 10^{22.4}$ . For acid solns. in which the H ion exponent ( $p_H$ ) is less than 9.3. ( $K_{\text{ion}}$  of  $\text{HCN} = 10^{9.3}$ )  $[\text{HCN}]/[\text{CN}^-] = [\text{H}^+]/K_{\text{ion}} = 10^{9.3 - p_H}$ . Eliminating  $[\text{CN}^-]$ ,  $\frac{[\text{Au}(\text{CN}^-)_2] \cdot [\text{SCN}^-]^2}{[\text{Au}(\text{SCN}^-)_2] \cdot [\text{HCN}]^2} = 10^{3.8 + 2p_H}$ . In  $[\text{H}^+] = 1$ , ( $p_H = 0$ ) 2HCN per  $\text{Au}(\text{SCN}^-)_2$  will displace 95% of the  $\text{SCN}^-$ .  $[x/(1-x)]^2 = 10^{3.8}$ ; ( $x = 0.95$ ). In spite of its small stability relative to aurocyanide ion, in presence of excess  $\text{SCN}^-$  aurothiocyanate complex is so little hydrolyzed that the free acid in its soln. can be accurately titrated with NaOH and phenolphthalein. In absence of excess  $\text{SCN}^-$  it is quickly decompd. partially by pure water. Gold electrodes dissolve in aurithiocyanate solns. according to  $2\text{Au} + \text{Au}(\text{SCN}^-)_4 + 2\text{SCN}^- = 3\text{Au}(\text{SCN}^-)_2$ . Pt foil in mixts. of auro- and aurithiocyanate gave a well-defined potential which was found due to the reversible transition between auro- and aurithiocyanate while the Pt was not attacked. Through measurement of this potential could be calcd.: (1) from its change with compn. of the soln., the formula of the aurithiocyanate ion from  ${}_0E = {}_0E' - (RT/2F) \ln ([\text{Au}^{\text{III}}]/[\text{Au}_2][\text{SCN}^-])^2$  based on the assumption of the reaction as aurocomplex +  $2\text{SCN}^- = \text{auricomplex} + 2e$ ; the values of  ${}_0E$  agreed well, showing the assumed reaction correct and the aurocomplex in soln. to be  $\text{Au}(\text{SCN}^-)_2$ ; (2) the normal potential of auro-aurithiocyanate; at  $18^\circ$  the value of  ${}_0E$  found was 0.308v. and for  ${}_0E_h$  0.645 v.; for  $\text{I}_2$  (solid) +  $2e = 2\text{I}^-$ ,  ${}_0E_h = 0.54$  v. and for  $\text{Br}_2$  (liquid) +  $2e = 2\text{Br}^-$ ,  ${}_0E_h = 1.09$  v.;  $\text{Au}(\text{SCN}^-)_4$  is therefore a somewhat stronger oxidizing agent than  $\text{I}_2$  but much weaker than  $\text{Br}_2$ ; (3) the potential of  $\text{Au}(\text{SCN}^-)_4 - \text{Au}$ ; since  $3E(\text{Au}(\text{SCN}^-)_4 - \text{Au}) = 2E(\text{Au}(\text{SCN}^-)_2 - \text{Au})(\text{SCN}^-)_2 + E(\text{Au}(\text{SCN}^-)_2 - \text{Au})$ , (Luther, *Z. physik. Chem.* 34, 488; 36, 385(1901)) for a soln. in which each ion species is 1 molar the  $E$  values are the normal potentials and  $3{}_0E = 2 \cdot 0.645 + 0.689$ ; whence  ${}_0E_h = 0.660$  v.; (4) the stability of the aurithiocyanate ion; combining the normal potentials of  $(\text{Au}(\text{SCN}^-)_4 - \text{Au})$  and  $(\text{AuCl}_4 - \text{Au}) = 1.001$  v. (see below),  ${}_0E - {}_0E' =$

$(RT/3F) (\ln (K'/K)) (K'/K) = 10 [(1.001 - 0.660)/0.0193] = 10^{17.67}$ ; the aurithiocyanate complex has a stability  $K$  about  $10^{17.7}$  times that of aurichloride ion; (5) the value of  $[\text{Au}(\text{SCN}^-)_2]/[\text{Au}(\text{SCN}^-)_4]$  in a gold thiocyanate soln. of unknown compn. can be detd. In the solns. used  $[\text{SCN}^-] = 0.1-0.4$  molar;  $[\text{H}^+] = \text{approx. } 1$ . By spectrophotometric and soly. detns. the presence of  $\text{Au}(\text{SCN}^-)_2$  and  $\text{Au}(\text{SCN}^-)_4$  in solns. of higher  $[\text{SCN}^-]$  was proved and they predominate in solns. of  $[\text{SCN}^-] = 2-4$  molar. They are deeper colored than  $\text{Au}(\text{SCN}^-)_4$ ; at  $\lambda = 578\mu$ , the molar extinction coeff. ( $m\epsilon k = \log (I_0 : I)/l \cdot C$ , where  $l$  is the layer thickness in cm.,  $C$  the molar concn. of Au,  $I_0$  the intensity of the incident, and  $I$  intensity of the emergent light) of  $\text{Au}(\text{SCN}^-)_4$  is 108; of  $\text{Au}(\text{SCN}^-)_2$  about 218; of  $\text{Au}(\text{SCN}^-)_4$  about 248. The stability const. were detd.;

$$K_{\text{Au}(\text{SCN})_2} = \frac{[\text{Au}(\text{SCN}^-)_2]}{[\text{Au}(\text{SCN}^-)_4] \cdot [\text{SCN}^-]} = 1.0; K_{\text{Au}(\text{SCN})_4} = \frac{[\text{Au}(\text{SCN}^-)_4]}{[\text{Au}(\text{SCN})_2] \cdot [\text{SCN}^-]} = 1.1.$$

At small concns. of  $\text{H}^+$  and  $\text{SCN}^-$ ,  $\text{Au}(\text{SCN}^-)_4$  appears to be hydrolyzed with formation of  $\text{Au}(\text{SCN}^-)_2\text{OH}$  and  $\text{Au}(\text{SCN}^-)_2(\text{OH})_2$ ; at  $[\text{H}^+], [\text{SCN}^-] = 0.01$  this hydrolysis is probably not more than 20%. All gold thiocyanate solns. sep. out Au after intervals depending on external conditions. This autoreduction was found to result from 2 reactions:  $3\text{Au}(\text{SCN}^-)_4 + 4\text{H}_2\text{O} \longrightarrow 3\text{Au}(\text{SCN}^-)_2 + 5\text{HSCN} + \text{HCN} + \text{H}_2\text{SO}_4$ , irreversible, and  $3\text{Au}(\text{SCN}^-)_2 \rightleftharpoons 2\text{Au}_2\text{Au}(\text{SCN}^-)_4 + (\text{SCN})_2$ , reversible. The conclusion that free thiocyanogen,  $(\text{SCN})_2$ , exists, was reached as follows: Analytical detns. showed uniformly that for 3 atoms Au reduced 1 mol. of  $\text{H}_2\text{SO}_4$  and 8 equivs. acid were formed. The course of the reaction could be followed through decrease of color or by titration with  $\text{Na}_2\text{SO}_3$  of the unreduced Au. The reaction velocity decreased more rapidly than for even a trimol. reaction and this was found due to the repressive effect of  $\text{Au}(\text{SCN}^-)_2$ . The reaction was clearly irreversible since  $\text{H}_2\text{SO}_4$  and  $\text{HCN}$  could not oxidize  $\text{Au}(\text{SCN}^-)_2$  to  $\text{Au}(\text{SCN}^-)_4$ . Potential measurements with Pt electrodes indicated that in fresh  $\text{Au}(\text{SCN})_4$  solns. 10-20% of the Au was present as  $\text{Au}(\text{SCN}^-)_2$ , while sulfite titration showed all the Au in the auric condition. Spectrophotometric detns. agreed nearly quant. with electrometric; the degree of dissociation was found to be independent of  $[\text{H}^+]$  and  $[\text{SCN}^-]$  and to follow the Ostwald diln. law, showing that only two products were formed; since one was certainly  $\text{Au}(\text{SCN}^-)_2$ , the other must be  $(\text{SCN})_2$ .

$$\text{The mean value of the dissociation const., } K = \frac{[\text{Au}(\text{SCN}^-)_2] \cdot [(\text{SCN})_2]}{[\text{Au}(\text{SCN}^-)_4]} = 0.49 \cdot 10^{-4},$$

was found. It increased about 8% per degree. Measurements of the velocity of the autoreduction at 18° could be expressed with good approximation by  $-\frac{d[\text{Au}^{\text{III}}]}{dt} =$

$$5 \cdot \frac{[(\text{SCN})_2]^2}{[\text{H}^+]^2 \cdot [\text{SCN}^-]^2}.$$

The normal potential of  $(\text{SCN})_2 - \text{SCN}^-$  was calcd. from that of  $\text{Au}(\text{SCN}^-)_2 - \text{Au}(\text{SCN}^-)_4$ ,  $E$ , and the dissociation  $K$  of  $\text{Au}(\text{SCN})_4$  through which  $[(\text{SCN})_2]$  in an  $\text{Au}(\text{SCN}^-)_2 - \text{Au}(\text{SCN}^-)_4$  soln. is detd., by  $E' = E - (RT/2F) \ln K$ , from which  $E' = 0.769$ ; for I the corresponding normal potential is 0.54 and that for Br is 1.09. Thiocyanogen is thus an unstable halogen intermediate between Br and I; in agreement with this  $\text{Br}_2$  was found to be instantly reduced by a  $\text{HCl}$  soln. of  $\text{NaSCN}$ ; the resulting colorless soln. sets free I from  $\text{KI}$ . The capacity to displace I vanishes rapidly. Measurements of the rate of disappearance of this capacity could be expressed by the above velocity equation and the  $K$  found was approx. 5, completely confirming the results from the autoreduction measurements and raising to certainty the hypothesis that the autoreduction is due to formation of free  $(\text{SCN})_2$ . With the halogenic character of thiocyanogen established, the proportionality of the autoreduction velocity to the inverse squares of  $[\text{H}^+]$  and  $[\text{SCN}^-]$  is readily explained by the assumption that  $(\text{SCN})_2$  is hydrolyzed like  $\text{Cl}_2$  to  $\text{HCNSO}$  and  $\text{HCNS}$ ; if 2 mols.  $\text{HCNSO}$  unite,  $-\frac{d[\text{Au}^{\text{III}}]}{dt} =$

$k$ .  $[\text{HCNSO}]^2$ ; by combining with  $([\text{HCNSO}][\text{CNS}^-][\text{H}^+]/[(\text{SCN})_2] = K$  and eliminating  $[\text{HCNSO}]$ ,  $-d[\text{Au}^{\text{III}}]/dt = kK_2\{[(\text{SCN})_2]^2/([\text{H}^+]^2[\text{CNS}^-]^2)\}$ . The analytically detd. reaction for the auto reduction,  $3\text{Au}(\text{SCN})_2 + 4\text{H}_2\text{O} = 3\text{Au}(\text{SCN})_2 + 5\text{HCNS} + \text{HCN} + \text{H}_2\text{SO}_4$ , could be due to the partial reactions:  $\text{Au}(\text{SCN})_2 \rightleftharpoons \text{Au}(\text{SCN})_2 + (\text{SCN})_2$ , instantaneous; (2)  $(\text{SCN})_2 + \text{H}_2\text{O} \rightleftharpoons \text{HCNSO} + \text{H}^+ + \text{SCN}^-$ , instantaneous; (3)  $2\text{HCNSO} \rightarrow \text{H}^- \text{CNSO}_2 + \text{H}^+ + \text{CNS}^-$ , rapid; (4)  $\text{HCNSO} + \text{HCNSO}_2 \rightarrow \text{HCNSO}_2 + \text{H}^+ + \text{CNS}$ , instantaneous;  $\text{HCNSO}_2 + \text{H}_2\text{O} \rightarrow \text{HCN} + \text{H}_2\text{SO}_4$ , instantaneous; (3) alone, because of its relative slowness, detd. the velocity of the autoreduction. The velocity  $K$  increased about 11% per degree. Aurothiocyanate solns. deposit Au according to  $3\text{Au}(\text{SCN})_2 = 2\text{Au} + \text{Au}(\text{SCN})_2 + 2\text{SCN}^-$ ; the reaction is reversible since aurothiocyanate solns. dissolve Au with formation of  $\text{Au}(\text{SCN})_2$ . For the  $K_{\text{equil}} = \frac{[\text{Au}(\text{SCN})_2][\text{SCN}^-]^2}{[\text{Au}(\text{SCN})_2]^3}$ , the value 33 (approx.) was found. It increases

rapidly with decreasing  $[\text{SCN}^-]$  and slowly with decreasing  $[\text{H}^+]$ . Addn. of gold dust hastens it catalytically. In 0.1 mol.  $\text{HCl}$ , 0.5 mol.  $\text{NaSCN}$ , 0.1 mol.  $\text{Au}^{\text{I}}$  at  $40^\circ$ , about 0.5 of the gold seps. in 3 days. Three series of detns. of the p. d. between gold electrodes and  $\text{AuCl}_4^-$  in  $[\text{HCl}]$  sufficient to suppress dissocn. of the complex gave for  $\phi E$  0.671, 0.655, 0.665; av., 0.664, whence  $\phi E_{\text{H}} = 1.001$  v. The considerable uncertainty of the p. d. is probably due to presence of  $\text{Au}^{\text{I}}$ . From the p. d. in 0.1 mol.  $\text{HAuCl}_4$  without addn. of  $\text{HCl}$ ,  $\phi E = 0.817$  v., was calcd. the hydrolysis according to  $\text{AuCl}_4^- + \text{H}_2\text{O} = \text{AuCl}_2\text{OH}^- + \text{H}^+ + \text{Cl}^-$  from  $E' = \phi E + (RT/3F) \ln [0.1(1-x)/(0.1x)^4]$ , whence  $x = 0.069$  or 6.9% hydrolysis in 0.1 mol. soln. For the hydrolysis const.,  $K_h = 0.55 \cdot 10^{-4}$  was calcd. From this value  $\text{HAuCl}_4$  should be hydrolyzed 0.74% in 1 mol. and 45.0% in 0.01 mol. soln. The analytical, electrometric and spectrophotometric data are presented in 55 tables.

A. R. MIDDLETON.

**The ternary system  $\text{CaO-MgO-SiO}_2$ .** J. B. FERGUSON AND H. E. MERWIN. Geophys. Lab., Washington. *Proc. Nat. Acad. Sci.* 5, 16-8(1919); cf. *C. A.* 12, 1718.—This paper presents a summary of the results obtained in a study of the remainder of the fourth ternary system of  $\text{CaO-Al}_2\text{O}_3\text{-MgO-SiO}_2$ . Phases not previously noted are  $\text{CaO} \cdot \text{SiO}_2 \cdot 2\text{CaO} \cdot \text{MgO} \cdot 2\text{SiO}_2$  solid solns. and the *compd.*,  $2\text{CaO} \cdot \text{MgO} \cdot 2\text{SiO}_2$ , which has optical properties practically identical with the mineral *akermanite*. The summarized temp.-concn. relations are shown on a triangular diagram which includes (1) the location of the fields with their boundary curves, (2) the location of the invariant points, (3) the temps. corresponding to the fixed pts., (4) the isotherms which indicate the slopes of the various fields upon a solid model.

A. R. MIDDLETON.

**Amorphous precipitated silica.** P. BRAESCO. *Compt. rend.* 168, 343-5(1919).—Measurements of thermal expansion were made on pptd.  $\text{SiO}_2$  calcined to different temps., using the registering differential dilatometer previously described (*C. A.* 11, 2743). The material was first dehydrated at a dull red heat and successive portions were heated to different temps. up to  $1600^\circ$ . From these, small briquets,  $6 \times 8 \times 50$  mms., were molded under pressure using 5% by wt. of sodium silicate as a binder. The test pieces were then reheated to  $600^\circ$  to insure sintering. It was found that pptd.  $\text{SiO}_2$ , dehydrated and heated only to  $600^\circ$ , behaves exactly like silica glass, which has a small coeff. of expansion. This then is certainly amorphous  $\text{SiO}_2$ . But when calcined to  $1000^\circ$  or above, it shows an abrupt change in expansion between  $220$ - $240^\circ$ , a property entirely characteristic of cristobalite, which, according to LeChatelier, shows at  $225^\circ$  an allotropic change, accompanied by a sharp expansion of 0.98%. The observed total expansion for pptd.  $\text{SiO}_2$  calcined to  $1100^\circ$  and  $1400^\circ$  is 0.80%; and to  $1600^\circ$ , 0.90%. Pptd.  $\text{SiO}_2$ , therefore, which has been calcined to a temp. above  $1000^\circ$  is no longer amorphous, but corresponds to cristobalite.

A. L. FIELD.

**Preparation of organic chlorostannites and -stannates. I. Salts of aliphatic amines.** J. G. F. DRUCE. *Chem. News* 118, 1-3(1919); cf. C. A. 13, 289.—The preps. of Cook (*Am. Chem. J.* 22, 435(1899)) were successfully reproduced. In addition the diethylamine salts were prepd. The *chlorostannite*,  $(Et_2NH)_2H_2SnCl_4$ , was prepd. by warming 3.65 g.  $Et_2NH$  and 5.65 g.  $SnCl_4$  in 70 cc. dil. HCl and concg. to 0.5 vol. Deliquescent crystals, m.  $58^\circ$ . The *chlorostannate* was prepd. by treating 4 g. of the *chlorostannate* in 50 cc. dil. HCl with  $Cl_2$  for 1.5 hrs. and evapg. to small vol., slightly deliquescent crystals, m. with decompn. at  $260^\circ$ ; formula  $(Et_2NH)_2H_2SnCl_4$ . An identical product in larger crystals was obtained by dissolving 4.7 g. of the base and 11.7 g.  $SnCl_4$  in 100 cc. dil. HCl. Methylamine chlorostannite was also prepd. by reduction of MeCN with Sn and HCl and the chlorostannite by reduction with  $SnCl_2$ ; in neither case was the reaction quant. The products were identical with those prepd. by Cook's methods. The reduction of nitriles by Sn or  $SnCl_2$  and HCl appears to be a general reaction. Examples of the reaction are:  $MeCN + 2Sn + 5HCl = EtNH_2.HSnCl_4 + SnCl_2$  and  $2MeCN + 4SnCl_2 + 10HCl = (EtNH_2)_2.H_2SnCl_4 + 3SnCl_4$ .

A. R. MIDDLETON.

**Preparation of organic chlorostannites and -stannates. J. G. F. DRUCE.** *Chem. News* 118, 87-9(1919); cf. preceding abstract.—The following salts are described *aniline chlorostannites*,  $PhNH_2.HSnCl_4.H_2O$ , m.  $105^\circ$  (decompn.);  $(PhNH_2)_2.H_2SnCl_4$ , m.  $160^\circ$ , decomp.  $219^\circ$ , dil. HCl solns. oxidize on standing to the chlorostannate *o-toluidine chlorostannite*,  $(C_7H_7NH_2)_2.H_2SnCl_4$ , m.  $164^\circ$ ; *o-toluidine chlorostannate*  $(C_7H_7NH_2)_2.H_2SnCl_4.H_2O$ , m.  $210^\circ$  (decompn.), and  $(C_7H_7NH_2)_2.H_2SnCl_7.2H_2O$ , m.  $92^\circ$ ; *p-toluidine chlorostannite*,  $(C_7H_7NH_2)_2.H_2SnCl_4$ , m.  $239^\circ$ ; *p-toluidine chlorostannate*,  $(C_7H_7NH_2)_2.H_2SnCl_4.H_2O$ , m.  $298^\circ$  (decompn.); *methylaniline chlorostannite*,  $(PhNHMe).HSnCl_4$ , m.  $106^\circ$ ; *methylaniline chlorostannate*,  $(PhNHMe)_2.H_2SnCl_4$ , m.  $251^\circ$  (decompn.); *dimethylaniline chlorostannite*,  $(PhNMe_2).H_2SnCl_4$ , m.  $87^\circ$ , and *chlorostannate*,  $(PhNMe_2)_2.H_2SnCl_4$ , m.  $166^\circ$ , decomp.  $124^\circ$ ; attempts to prep. *o*-phenylenediamine salts by reduction of *o*-nitroaniline with Sn and HCl or by  $SnCl_4.2H_2O$  lead to no definite compd.; *m-phenylenediamine chlorostannite*,  $C_6H_4(NH_2)_2.HSnCl_4$ , m.  $128^\circ$ , and *chlorostannate*,  $C_6H_4(NH_2)_2.H_2SnCl_4$ , decomp.  $264^\circ$ ; *p-phenylenediamine chlorostannite*,  $C_6H_4(NH_2)_2.H_2SnCl_4$ , m.  $270^\circ$  (decompn.), and *chlorostannate*,  $C_6H_4(NH_2)_2.H_2SnCl_4$ , m.  $230^\circ$  (decompn.); *pyridine chlorostannite*,  $PySnCl_3.HCl$ , m.  $115^\circ$ , and *chlorostannate*,  $Py_2H_2SnCl_4$ , m.  $305^\circ$ ; *quinoline chlorostannite*,  $C_8H_7N.HSnCl_4$ , m.  $127^\circ$ , and *chlorostannate*,  $(C_8H_7N)_2.H_2SnCl_4$ , m.  $258-9^\circ$ . Methods of prepn. have been given in previous papers. All these salts are decompd. by water, some quickly by cold water, others slowly upon warming.

## 7. ANALYTICAL CHEMISTRY.

E. G. R. ARDAGH.

**Determining the composition of a mixture of similar salts of two metals.** W. R. FIELDING. *Chem. News* 118, 107-8(1919).—*I. Alloy containing 2 metals:* Weigh out a small portion of the alloy, dissolve it in  $HNO_3$ , evap. to dryness, heat until fumes cease to be evolved, and weigh. By equilogarithm calc. the compn. of the alloy. *II. Alloy containing 3 metals:* Convert 1 g. of it into its mixed oxides, and weigh. From a weighed portion of the alloy sep. one component and convert it to its oxide, weigh, and solve the compn. of the alloy by equilogarithm.

EARLE M. BILLINGS.

**Standard alkali for mixed-acid control.** E. HEARSEY AND C. M. JOYCE. *J. Ind. Eng. Chem.* 11, 341(1919).—The authors recommend the use of a standard NaOH soln. prepd. by the procedure of Cowles (cf. *C. A.* 2, 2355), with direct standardization with acid K phthalate as proposed by Dodge. Cf. *C. A.* 9, 277; Hendrixson, *Ibid* 2853. F. W. SMITHIER.

**Method of determining halogens, sulfur and nitrogen in presence of mercury.** MAURICE FRANÇOIS. *Ann. chim.* 11, 5-15(1919).—See *C. A.* 12, 2073. E. J. C.

**Determination of nitrous acid and nitrites.** J. S. LAIRD AND T. C. SIMPSON. Univ. Michigan. *J. Am. Chem. Soc.* 41, 524-31(1919).—Volumetric methods for  $\text{HNO}_2$  in the literature are reviewed and rejected as not satisfactory. The proposed method consists in oxidizing the nitrite in acid soln. with excess  $\text{KMnO}_4$ , reducing this excess with excess  $\text{FeSO}_4$ ,  $\text{Na}_2\text{C}_2\text{O}_4$  or  $\text{H}_2\text{O}_2$ , and titrating the excess reducing agent with  $\text{KMnO}_4$ . Moderate amts. of chloride and small amts. of bromide do not interfere.  $\text{AgNO}_3$  is not a satisfactory standard material for use in connection with quant. detns. of nitrites. Standard  $\text{NaNO}_2$  should be run against known  $\text{KMnO}_4$  by the method given, or the nitrite may be detd. gravimetrically by the reduction of  $\text{AgBrO}_3$ .

E. B. MILLARD.

**Study of the conditions affecting the precise determination of zinc as sulfide.** HAROLD A. FALES AND GERTRUDE M. WARE. *J. Am. Chem. Soc.* 41, 487-99(1919).—The pptn. of Zn from solns. in formic acid by means of  $\text{H}_2\text{S}$  has been studied with special reference to conditions affecting the accuracy of the detn. The most favorable range of  $\text{H}^+$  concn. for quant. pptn. of ZnS in a form suitable for rapid filtering and washing is 0.01 to 0.002. The concn. may be kept within this range during pptn. by means of "buffers," i. e., mixts. of formic acid,  $\text{NH}_4$  citrate,  $(\text{NH}_4)_2\text{SO}_4$ ,  $\text{HCO}_2\text{NH}_4$  and  $\text{HCO}_2\text{H}$ . Granular ZnS is favored in the pptn. not only by a  $\text{H}^+$  concn. within the limits given, but also by a high concn. of  $\text{NH}_4$  salt of a strong acid, by a vol. of 100 cc. for each 0.1 g. of Zn present and by a temp. of 95 to 100°. Passing of  $\text{H}_2\text{S}$  under pressure is desirable both for rapid satn. and to avoid loss of  $\text{HCOOH}$  by evapn. ZnS may be converted into  $\text{ZnSO}_4$  by the direct treatment with  $\text{H}_2\text{SO}_4$  after igniting the filter paper (cf. Sullivan and Taylor, *C. A.* 3, 2279). Test analysis show that the method is applicable to the sepn. of Zn from Fe, Mn and Ni and to the analysis of Zn alloys and ores. If the conditions given in detail in the paper are followed, the method is accurate to 1 part in 1000. E. B. MILLARD.

**The determination of phosphorus in steel, iron, and phosphatic slags.** A. TRAVERA. *Chimie & industrie* 2, 133-41(1919).—T. reviews and discusses the different procedures that have been proposed for the pptn. of phosphomolybdate, and reports in detail a series of expts. made to det. the conditions for obtaining a ppt. of the compn.  $\text{P}_2\text{O}_5 \cdot 24\text{MoO}_3 \cdot 3(\text{NH}_4)_2\text{O} \cdot 3\text{H}_2\text{O}$ . A decided excess of the  $\text{MoO}_3$  reagent should be used (equiv. to 1 to 1.5 g.  $\text{MoO}_3$ ) and the addition of  $\text{NH}_4\text{NO}_3$  suppressed. With the acid concn. usually employed, increasing the excess of  $\text{MoO}_3$  or of  $\text{NH}_4\text{NO}_3$  increases the danger of entraining free  $\text{MoO}_3$ ; this is greatly augmented in a slightly acid medium. Increasing the free acid concn. diminishes the chances of entrainment. T. recommends the following rapid method for routine work: Dissolve 1 g. of steel in a beaker in 15 cc. of  $\text{HNO}_3$  (d. 1.2); oxidize with  $\text{KMnO}_4$  soln. (20 g. per l.), dissolve  $\text{MnO}_2$  and destroy  $\text{HMnO}_4$  with a few drops of  $\text{NaNO}_2$  soln., and add 10 cc. of  $\text{HNO}_3$  (d. 1.33); cover with a watch glass, boil 3 to 4 min., pour into the boiling soln. 25 to 30 cc. of the cold  $\text{MoO}_3$  soln.; stir with a glass rod, striking the sides of the vessel, for 1½ min., transfer to calibrated (against a standard steel) tube, centrifuge, and read off % P. With high Si alloys, add 1 or 2 cc. of HF with the  $\text{HNO}_3$ , and evap. till sirupy; take up with  $\text{HNO}_3$  and proceed as outlined; W. is removed in the usual manner as  $\text{WO}_3$ ; V

and P are sepd. by pouring the soln. into a large excess of boiling NaOH soln.; after filtering, neutralize the soln., add a soln. of an Al salt, and then  $\text{NH}_4\text{OH}$ ; filter, dissolve the  $\text{AlPO}_4$  in  $\text{HNO}_3$  and ppt. the P with  $\text{MoO}_3$  as above. On redissolving a ppt. obtained in a strongly acid medium and reprecip. in a feebly acid medium, the ppt. will contain some free  $\text{MoO}_3$ . The following *slow* method is used in the Creusot works: Treat 1 g. of steel with 15 cc.  $\text{HNO}_3$  (d. 1.20); after action ceases, add 3 cc. HCl, and evap. to dryness, take up with 5 cc.  $\text{HNO}_3$  (d. 1.33) and 5 cc. HCl, cover, and heat to boiling. Add 10 cc. of  $\text{H}_2\text{O}$ , and when all sol. matter is in soln. filter off the  $\text{SiO}_2$ , wash with 2%  $\text{HNO}_3$ , add to the filtrate 25 cc. of  $\text{MoO}_3$  reagent, heat at  $65^\circ$  for 3 hrs., filter on tared filters, wash with 2%  $\text{HNO}_3$ , dry 1 hr. at  $130^\circ$  to  $140^\circ$ , cool, and weigh. *Reagent:* Dissolve at room temp. 100 g. of pure  $\text{MoO}_3$  in 400 cc. of  $\text{NH}_4\text{OH}$  (d. 0.96) and pour the soln. in a const. stream, with stirring into 1250 cc. of  $\text{HNO}_3$  (d. 1.2); heat on a  $\text{H}_2\text{O}$  bath at 60 to  $65^\circ$  for 2 days, and filter. To obtain correct results by the "slow" method, the following conditions should be observed: (a) steel: 20 cc. of  $\text{MoO}_3$  soln. to 30 cc. of soln. (filtrate from  $\text{SiO}_2$ ); (b) Thomas Fe: 25 cc. of reagent under same conditions as (a), working on 0.2 g.; (c) Thomas slag: 25 cc. of reagent in same vol. of soln. as in (a), working on 0.1 g. After evap. to dryness to render  $\text{SiO}_2$  insol., take up with 5 to 7 cc. of  $\text{HNO}_3$  (d. 1.33) and 5 cc. HCl and cover the beaker with a watch glass. The evapn. for  $\text{SiO}_2$  should be carried out on a  $\text{H}_2\text{O}$  bath to facilitate the later re-soln. of the Fe. Filter on a very small paper and wash with a fine jet so that the soln. will not be dild. beyond 35 cc. In the av. control analysis the  $\text{SiO}_2$  and  $\text{Fe}_2\text{O}_3$  retained by the ppt. are of slight importance, e. g., the phosphomolybdate ppt. from 1 g. of steel contained less than 0.5 mg. of  $\text{Fe}_2\text{O}_3$  and less than 0.5 mg. of sol.  $\text{SiO}_2$ . Only in high concns. of chlorides or HCl (in taking up sample after evap. to dryness) is the subsequent pptn. incomplete;  $\text{H}_2\text{SO}_4$  or sulfates in large amts. interfere (the  $\text{HNO}_3$  used should not contain over 5% of  $\text{H}_2\text{SO}_4$  and should be As-free). Flourides or free HF in very small amts. render the pptn. incomplete, and may even prevent pptn. *Control detns. as  $\text{Mg}_2\text{P}_2\text{O}_7$ .* *Steel:* Treat 1 g. portion (about 50) as indicated above, and filter the phosphomolybdates on the same filter; dissolve in  $\text{NH}_4\text{OH}$  (1:3), filter (if necessary), add 1 to 2 g. of  $\text{NH}_4\text{Cl}$  and ppt. with Magnesia mixt. in usual manner. Let stand 24 hrs., filter, wash with dil.  $\text{NH}_4\text{OH}$ ; redissolve in HCl, evap. to dryness on the  $\text{H}_2\text{O}$  bath; take up with a few drops of HCl and 30 cc. of hot  $\text{H}_2\text{O}$ , filter off  $\text{SiO}_2$ , and wash; reprecip. in the presence of citric acid, let stand 12 hrs., filter, wash with cold, strongly ammoniacal  $\text{H}_2\text{O}$ , ignite, and weigh as  $\text{Mg}_2\text{P}_2\text{O}_7$ . *Thomas Fe:* Treat 2 g. with aqua regia ( $1\frac{1}{2}$   $\text{HNO}_3$ ), adding sufficient  $\text{AlCl}_3$  to yield 0.3 g. of  $\text{Al}_2\text{O}_3$ ; neutralize with  $\text{NH}_4\text{OH}$  until the ppt. formed just redissolves, cool, add a soln. of 8 to 10 g. of  $\text{Na}_2\text{S}_2\text{O}_8$ , and boil about 15 min., adding very dil.  $\text{NH}_4\text{OH}$  dropwise from time to time to assure almost complete neutrality (use litmus paper). Let settle, decant rapidly, wash by decantation with boiling  $\text{H}_2\text{O}$ ; finally ignite the ppt. in a porcelain crucible. Treat in Pt with HF and  $\text{H}_2\text{SO}_4$  to remove  $\text{SiO}_2$ ; fuse with about 10 g. of  $\text{Na}_2\text{CO}_3$ , take up with 50 cc. of boiling  $\text{H}_2\text{O}$ , filter and wash; acidify with  $\text{HNO}_3$ , add 40 cc. of  $\text{NH}_4$  citrate soln. (150 g. of citric acid per l.), a slight excess of Magnesia mixt., 2 to 3 g. of  $\text{NH}_4\text{Cl}$ , and an excess of  $\text{NH}_4\text{OH}$ ; stir, let stand 12 hrs., filter, wash with cold, strongly ammoniacal  $\text{H}_2\text{O}$ , and finally ignite and weigh as  $\text{Mg}_2\text{P}_2\text{O}_7$ . It is preferable to make a double pptn. to eliminate Na salts. *Slags:* The direct pptn. of the  $\text{P}_2\text{O}_5$  by Mg mixt. may be made by the usual citric acid procedure without removing Fe. The slag should be finely powdered, and the  $\text{SiO}_2$  eliminated by 2 evapns. on the  $\text{H}_2\text{O}$  bath. The  $\text{SiO}_2$  retains about 0.1% of  $\text{P}_2\text{O}_5$ , which can be recovered or taken into account. T. also outlines the methods of detg.  $\text{P}_2\text{O}_5$  by titrating  $(\text{NH}_4)_2\text{ZnPO}_4$  or  $(\text{NH}_4)_2\text{MgPO}_4$  (pptg. hot) with acid and Me orange.

F. W. SMITHER.

The determination of uranium in alloy steels and ferro-uranium. G. L. KELLEY,

F. B. MYERS AND C. B. ILLINGWORTH. *J. Ind. Eng. Chem.* 11, 316-7(1919).—The method is described in detail. It provides for the presence of Cr, Mo, V, W, Co, Ni, C, Mn, Si, P, and S. F. W. SMITHER.

The testing of sodium bisulfite in the laboratory of the A. V. R. O. S. F. C. VAN HEURN. *Arch. Rubbercult. Nederland. Indië* 2, 12-21; *Meded. Alg. Proefstat. Alg. Ver. Rubberplanters Oostkust Sumatra, Rubber Ser.* No. 6, 12-21(1918); *Expt. Sta. Rec.* 39, 413.—V. states that technical samples of  $\text{NaHSO}_3$  generally contain in addition to the bisulfite itself, some  $\text{Na}_2\text{SO}_3$  and  $\text{Na}_2\text{SO}_4$ . The second component is most valuable, while the third is quite worthless. In dissolving the sample for analysis the  $\text{NaHSO}_3$  becomes  $\text{Na}_2\text{SO}_3 + \text{H}_2\text{SO}_3$ . Taking this into consideration, the following method of analysis has been developed: About 1 g. of the material is weighed in a weighing tube, a small quantity of water added, and the soln. poured into a graduated glass-stoppered volumetric flask and made up to 1 l. This soln. is used for all detns. To det. the amt. of  $\text{SO}_2$  present as real bisulfite, 100 cc. of the soln. is placed in an Erlenmeyer flask and titrated with 0.1 N KOH, using phenolphthalein as an indicator. Double the quantity of  $\text{SO}_2$  found is present as bisulfite. This amt. multiplied by 1.63 ( $\text{NaHSO}_3/\text{SO}_2 = 1.63$ ) gives the max. amt. of  $\text{NaHSO}_3$  that can be present. To det. the total amt. of  $\text{SO}_2$ , some of the original soln. is placed in a buret and titrated with 25 cc. of 0.1 N I. The amt. of  $\text{SO}_2$  present as normal sulfite is then found by subtracting from the total  $\text{SO}_2$  the amt. present as bisulfite. To det. the amt. of sulfate 100 cc. of the soln. is placed in an Erlenmeyer flask, and 1 cc. of concd. HCl and a few drops of alc. are added. The air in the flask is replaced by  $\text{CO}_2$ , and the soln. is heated and pptd. with a 10% soln. of  $\text{BaCl}_2$ . E. J. C.

Sodium pyrogallate solution as an absorbent for oxygen. G. W. JONES AND M. H. MEIGHAN. *J. Ind. Eng. Chem.* 11, 311-6(1919).—"A new app. for testing the relative absorption of O with different solns. has been devised. Tests made over a wide range of concns. of the different reagents show that the rate of O absorption in Na pyrogallate solns. increases with the diln. of the NaOH and for any given concn. of NaOH the rate of absorption is proportional to the concn. of the pyrogallic acid. Na pyrogallate solns. made by using NaOH solns. of less than d. 1.30 give off CO which increases with the diln. All Na pyrogallate solns. give off CO when analyzing O samples containing above 95% O. A Na pyrogallate soln. which gives off a minimum amt. of CO, having a fairly high rate of absorption, and adapted for pipets, using glass tubes, is recommended, with directions for its prepn." F. W. SMITHER.

The determination of zinc and copper in gelatin. G. S. JAMIESON. *J. Ind. Eng. Chem.* 11, 323-5(1919).—J. describes in detail, with exptl. results, a method based on hydrolyzing the gelatin in HCl soln. and subsequently detg. the Cu and Zn by well known procedures. F. W. SMITHER.

## 8. MINERALOGICAL AND GEOLOGICAL CHEMISTRY.

---

EDGAR T. WHERRY AND J. H. BOWER.

Meteoric iron from Chili (Dehesa). F. BERWERTH. *Min. Petr. Mitth.* 34, 272; *J. Chem. Soc.* 114, II, 403(1918).—This mass was described by Daubrée in 1868, and was stated by Domeyko to have been found in the Cordillera de la Dehesa, near Santiago. From its compact appearance and Domeyko's analysis (Ni 14%), it was placed in the group of Ni-rich "compact irons." Microscopical examn. of an etched surface shows, however, that the structure is octahedral. The following new analysis (mean of 2 by

E. Dittler) was therefore made, showing that this iron belongs to the group of very fine octahedrites: Fe 87.40, Ni 11.97, Co 0.56, insol. (schreibersite) 0.07%. J. H. B.

International control of minerals. C. K. LEITH. U. S. Geol. Survey, *Mineral Resources of U. S., 1917*, Part I, 70-160 (Preprint B, published Dec. 31, 1918). E. H.

Banded structures of the Adirondack syenite-granite series. WILLIAM J. MILLER. *Science* 48, 560-3(1918).—Description and discussion of the origin of these structures. J. H. B.

Antimony in the Transvaal (GALBREATH) 9. System  $\text{CaO-MgO-SiO}_2$  (FERGUSON, MERWIN) 6.

## 9. METALLURGY AND METALLOGRAPHY.

WILLIAM BRADY, WILLIAM T. HALL.

Quicksilver in 1917. F. L. RANSOME. With a bibliography. I. P. EVANS. U. S. Geol. Survey. *Mineral Resources of U. S., 1917*, Pt. I, 367-455; Preprint No. 17 (published Mar. 18, 1919). E. J. C.

Production of pig iron in the United States in 1918. ANON. *Iron Age* 103, 889 (1918).—Tables of statistics. E. J. C.

Report of Allen Property Custodian on the metal industry. *Chem. Met. Eng.* 20, 313-7(1919). E. J. C.

Antimony in the Transvaal. N. M. GALBREATH. *J. S. Afr. Assoc. Anal. Chem.* 1918, 1, 9-10; *J. Soc. Chem. Ind.* 37, 626-7A(1918).—The deposits of the Murchison Range, N. E. Transvaal, contain up to 10% Sb and 4 dwt. Au per ton. Part of the latter is apparently enclosed in the stibnite, as cyaniding does not give good extn. Liquation on sloping triangular hearths has been tried;  $\frac{1}{3}$  of the Sb is extd., while the bulk of the Au remains in the residue. Flotation was fairly successful on an exptl. scale. S. G. GORDON.

Effect of air in cyanidation. N. S. KEITH. *Eng. Mining J.* 107, 522-3(1919).—A discussion. "It has been satisfactorily and practically demonstrated in many large cyanide mills that the removal of air from cyanide solns., before pptn., results in considerable savings of both cyanide and Zn." F. W. SMITHER.

Production of ferro-manganese in the blast furnace. P. H. ROYSER. *Bull. Am. Inst. Mining Eng.* 1919, 367-78.—See C. A. 13, 689. B. H. SMITH.

Experiments in fettling reverberatory furnaces. F. RUTHERFORD AND B. H. SMITH. *Eng. Mining J.* 106, 109-10(1918).—R. describes briefly exptl. work, carried out at the Copper Queen plant at Douglas, Ariz., in 1912, resulting in the adoption of the method of side-feeding hot calcines, as against center feeding of the hot calcines and side fettling with siliceous material. F. W. SMITHER.

New lead-zinc mill in Colorado. ANON. *Eng. Mining J.* 107, 397-8.—Central Colorado Mining Co. ore is handled by a system of Jeffrey conveyors, classified by trommel screens, and ground in ball mills for flotation. B. H. SMITH.

Dry gas cleaner. ANON. *Iron Age* 103, 766-7(1919).—A description of the Kling-Weidlein dry gas cleaner. The advantages claimed for the dry cleaning over wet washing of furnace gases are: (1) Sensible heat of the gas is retained; (2) when burned under boilers, the gas generates more steam; (3) when burned in hot blast stoves, it produces higher blast temp.; (4) no  $\text{H}_2\text{O}$  is required for cleaning the gas; (5) no settling basins are required; (6) less ground space is required; (7) there is no pollution of streams; (8) labor cost in handling the dust is less; (9) less than  $\frac{1}{10}$  the power is

required to operate; (10) there is less back pressure on the furnace; (11) cleaning efficiency is as good as in the best types of wet washers; (12) no sludge drips from gas mains and burners.  
F. W. SMITHER.

**Retreating zinc tailings in Wisconsin.** W. F. BORRICK. *Eng. Mining J.* 107, 524-7(1919).—An account of the attempts made to re-mill some of the old tailings dumps in the Wis.-Ill. field. In no case were operations undertaken on a large scale. Neither the size of the piles nor the Zn content of the tailings warranted large expenditures for equipment.  
F. W. SMITHER.

**Ruck zinc-distilling furnace.** ANON. *Eng. Mining J.* 107, 307-8(1919).—A special feature is the system of gas and air conduits in the front wall of the furnace to improve heating of the front ends of the retorts. Coal consumption is 1.15 tons per ton of ore.  
B. H. SMITH.

**International Nickel Company's refining works at Port Colborne, Ont.** W. L. WOTHERSPOON. *Eng. Mining J.* 107, 429-35(1919).—The works located on the shore of Lake Erie consist of 31 buildings, steel frame and brick walls. Among these are a sewage plant using the activated-sludge process, change houses, hospital and clubhouse. The mat is smelted with salt cake, Ni is sepd. and Cu is bessemerized in Allis-Chalmers converters with elec. tilting gear. Elec. driven, directly connected turbo blowers are used for cupolas. Flue gases are treated by a modern Cottrell pptn. plant. NiS is ground in ball mills, chemically treated and refined in specially designed oil-burning furnaces. All material is handled and weighed mechanically. Two special B. & W. boilers utilize in power plant the waste heat from Ni furnaces. Generators and blowers are run by Ridgway-Rateau h. p. turbines. Turbo-blowers are particularly economical of space. The plant has an annual capacity of 15,000,000 lb. Ni and 8,000,000 lb. Cu.  
B. H. SMITH.

**Applications of optical pyrometry in steel works practice.** J. N. GREENWOOD. *Trans. Faraday Soc.* 13, 295-308(1918).—Summary: "(1) The various conditions of use of an optical pyrometer in taking the temps. of liquid steel in the open have been compared with the calibration conditions, and have been shown to differ widely from them. (2) The errors due to the deviations considered in (1) have been shown to fall into 2 classes according to whether they were or were not accurately determinable. To the first class belong errors due to emissivity and polarization of the emitted light. To the second class belong such as are due to lack of monochromatism of the absorbing screen (absent in such types as the Wanner), to fumes, to light reflected from external sources, and to smallness of the source of light. (3) Several technical defects of the Cambridge optical pyrometer have been considered. (4) A suggestion has been made that in order to obtain control of the steel-making process pyrometrically, a refractory tube should be inserted into the bath when it is required to take the temps. A true black body condition would then be very nearly approached. (5) The use of optical pyrometry in the heat treatment of Fe and steel is next dealt with. It is shown that the scale on billets (formed during reheating) causes difficulties: (a) Inside the furnace at temps. below 800° to 900°, due to light reflected from the flames, (b) outside the furnace owing to its low thermal cond. (6) A comparison made between the Cambridge optical and the Siemens H<sub>2</sub>O pyrometer under normal working conditions has shown that, although the latter is capable of an accuracy of 10°, it is unreliable owing to the large personal factor involved."  
F. W. SMITHER.

**Optical pyrometry in non-ferrous metallurgy.** F. G. DONNAN. *Trans. Faraday Soc.* 13, 276-9(1918).—A discussion based on the work of Stubbs and Prideaux. Cf. C. A. 8, 862.  
F. W. SMITHER.

Steel from nickel-copper-iron ore shows high strength. R. W. LEONARD. *Eng. News-Rec.* 80, 812(1918).—The author reports the results of expts. in the production of a high-strength steel from the Sudbury Fe ores containing Cu and Ni. The product, known as "Nicu" steel, is to be made by the Nicu Steel Corporation. In an improvised plant at East Montreal 200 tons of ore and 40 tons of slag were smelted; after roasting, smelting with CaO flux in an elec. furnace performs the principal reduction, yielding a pig Fe of homogeneous compn.; this was refined to medium-C steel partly in an elec. furnace and partly in an open-hearth furnace using producer gas. The av. charge in the smelting furnace was 1400 lb. of roasted ore, 525 lb. of burned lime, and 375 lb. of coke breeze or coal. The av. analysis of the weathered ore was: Fe, 46; Ni, 1.3; Cu, 0.28; SiO<sub>2</sub>, 19.9; Al<sub>2</sub>O<sub>3</sub>, 3.8; S, 1.5 to 3; CaO, 2.7; MgO, 1.3%. The pig Fe produced averaged: S, 0.09; P, 0.07; Mn, 0.18; Si, 1.75; C, 3.0; Ni, 2.20; Cu, 0.40%. The company believes that equally satisfactory results can be obtained by smelting in an ordinary blast furnace after roasting the ore to about 1.5% S and then nodulizing in rotary kilns. In 10 of the heats, steel was produced having: C, 0.17; to 0.73 Si, 0.012 to 0.032; S, below 0.048; P, generally below 0.01%. The sum of Ni and Cu ranged from 1.25 to 2.5%, Cu usually being about 1/4 of the total. Tests showed: tensile strength, 96,500 lb./sq. in.; yield point, 52,800; elongation (in 2 in.), 24.3%; reduction of area, 50.8%; and a 180° bend test flat without cracking. The combined Ni and Cu in this specimen was 2.26%. "Nicu" steel has not as yet been manufd. on a com. scale.

F. W. SMITHER.

Electric arc welding. R. E. KINKAD. *Engineering* 106, 185, 213-5(1918).—In autogenous welding by the elec. arc and O-C<sub>2</sub>H<sub>2</sub> processes the metals are heated to a liquid state, poured together into a homogeneous molten mass and allowed to cool. With very few exceptions the same operations may be performed by either process, but the very great localization of the heat in arc welding gives it a marked advantage over O-C<sub>2</sub>H<sub>2</sub> for welding on boiler-plate and sheet metal. The higher temp. of the arc and the greater heat localization enable it to do at least 3 times more welding with the same amt. of heat than is possible with O-C<sub>2</sub>H<sub>2</sub>. The approx. heat quantities involved in the welding arc are expressed by the formula  $H = E \times I / 1000 \times T \times 3413$ , where  $H$  = heat in B. t. u.,  $E$  = av. e. m. f. across arc,  $I$  = av. current in arc circuit,  $T$  = time arc is in operation in hrs., and 3413 = heat equiv. of 1 kw.-hr. energy in B. t. u. The heat liberated by the O-C<sub>2</sub>H<sub>2</sub> flame may be calcd., knowing that 1 cu. ft. of an O-C<sub>2</sub>H<sub>2</sub> mixt. gives about 1550 B. t. u. The author discusses the applications of arc welding and gives comparisons of same with old methods and gas welding.

F. W. SMITHER.

Electric arc-welding apparatus. W. L. MERRILL. *J. Eng. Club Phil.* 35, 436-9 (1918); *Sci. Abstracts* 21B, 441(1918).—Successful welding can be done with both a. c. and d. c., and both systems have their advantages, the choice of either depending upon local conditions. The low voltage used for welding (12 to 15 v. on d. c., and 20 to 30 v. on a. c.) raises a problem in detg. the best method of distribution. The author discusses the various systems in use.

F. W. SMITHER.

Electric welding with covered electrodes. E. G. RIGBY. *J. Eng. Club Phil.* 35, 472-82(1918); *Sci. Abstracts* 21B, 406-7.—Welds made by plain Fe or C rods as electrodes are frequently deteriorated by pitting and oxidation, resulting in brittleness and porosity and breaking up of the metallic structure. Oxidation renders a joint peculiarly liable to corrosion. In the covered-electrode process the electrodes are surrounded by a covering of blue asbestos yarn which in fusing acts as a reducing agent, and by excluding the atm. from the fused metal prevents oxidation. The yarn is coated with silicate of Na, Al, or the like, to vary the fusing temp. The electrode, further, has combined with it a small amt. of metal capable of exerting a strong re-

ducing action, such as Al, in the form of a fine wire incorporated in the covering. Various methods of applying the process are described and illustrated in the original.

F. W. SMITHER.

**Electric arc welding in railway shops.** R. WANAMAKER. *Engineering* 106, 185-6 (1918).—The paper demonstrates the importance in war of elec. arc welding for repair work, especially in locomotive shops. A general description of the process is given, and comparisons are drawn between the elec. and other methods of welding.

F. W. SMITHER.

**Advantages of spot welding.** G. A. HUGHES AND R. H. POOL. *Elec. World* 73, 734-5 (1919).—A general outline of spot-welding methods is given with illustrations to show the effectiveness of elec. welds.

C. G. F.

**Practical data upon electric spot welding.** G. A. HUGHES AND R. H. POOL. *Elec. World* 72, 742-4 (1918).—Tests were made on 30-kw. 220-v. 60-cycle hand-operated machines. The data give an idea of power consumption, the strength of the weld and the speed at which welds can be made. Scale and rust cause arcing and burning. Weak and porous welds were avoided by burning off scale and rust by forcing the welding contacts firmly on the material and turning the power on the welder for a moment. Then the power was turned on and the material brought to welding heat without arcing. This saves cleaning the stock and increases the life of the welding points 50%.

W. H. BOYNTON.

**Heat treatment of low-carbon steel.** W. M. WILKIE. *Mech. Engr.* 41, 239-44 (1919).—The characteristic structures found in steel are described. The article deals at length on cast, (i. e., unworked) and hot-worked steel, cooled slowly, cooled rapidly, and reheated. A system of strengthening steels on high-explosive shells is known as the Sandberg air-cooling method, whereby rapid cooling by air increases the ultimate strength with an increase in the elastic ratio, but with very little variation in the ductility of the steel. By this method air at pressures ranging from 6 ozs. to 15 ozs. usually around 10 ozs., is either passed around the shell forging or forced to impinge on the revolving shell in such a way that a shell that would usually cool in 30 minutes in the open air, is cooled in six to eight minutes. By this method the strength is raised from 4,000 to 10,000 lbs. In an appendix the results on Electric and Basic Steels are given. This process was allowed free use to manufacturers of forgings during the war; it is applicable to steel rails to improve their wearing qualities.

E. G. JARVIS.

**Magnetic iron alloys.** ANON. *Ber. Phys.-Techn. Reichsanstalt* 1917; *Stahl u. Eisen* 38, 1043 (1918); *J. Soc. Chem. Ind.* 38, 17A.—In expts. made with a view to substitute Cr-steel for W-steel, it was found that in the case of bar magnets of Cr-steel left undisturbed for 1 year the alteration of the magnetic moment in the best specimens amtd. to only 0.1-0.3% and was within the limits of exptl. error in nearly all the specimens examd. during the latter half of the year. Suitable Cr-steels form an almost completely satisfactory substitute for W-steel magnets, but the "efficiency" as measured by the product of the remanence and coercive force is not quite so high in the case of the best Cr-steels as in that of the best W-steels.

E. J. C.

**Effects of phosphorus on malleable cast iron.** J. H. TENG. *Foundry* 47, 151-6 (1919).—See *C. A.* 12, 2524.

E. J. C.

**Influence of antimony on the mechanical properties of copper.** W. STAHL. *Metall u. Erz* 15, 395-6 (1918); *J. Soc. Chem. Ind.* 38, 43A.—The presence of 0.3-0.4% of Sb in pure Cu increases the hardness and general value of the metal. Admixt. of 0.15% of Ni and 0.15% of Sb also increases the hardness and quality of the metal provided that any flakes of oxide formed are removed by careful "poling" during the refining of the Cu. In Cu alloys contg. more than 2% Ni, Sb is harmful. It is also harmful

in Cu contg. Mn. In smelting Cu contg. 0.05% Bi, sufficient Sb should be added to convert the Bi into an antimonate. In the presence of Pb, Sb acts detrimentally on Cu, unless the Pb is present as antimonate.

E. J. C.

**Determination of the composition of binary alloys by specific-gravity determination.** M. VON SCHWARZ. *Bayr. Ind. u. Gewerbebl.* 104, 61-3(1918); *Z. angew. Chem.* 31, 310; *J. Soc. Chem. Ind.* 37, 738A.—In detg. the sp. gr. of alloys by Matthiessen's formula,  $d = 100/[(A/a) + (B/b)]$  where A and B are the percentages of the 2 metals in the alloy and *a* and *b* their sp. gr., an allowance must be made for the alteration in *d*. due to contraction and in a few cases for that due to expansion. The method of using the sp. gr. as a means of detg. the compn. finds practical application, principally for Sn-Pb and Sb-Pb alloys, of which samples of definite vol. can be cast and their wt. compared with those of similar substances of known compn. on the so-called Sn assay balance. Instead of the usual disk or conical samples, balls are now used which can be obtained uniform and of an exact vol. Using balls of a vol. of 1.62 cc. and weighing to 0.01 g., the compn. of Sn-Pb or Sb-Pb alloys can be obtained from the sp.-gr. curves with an accuracy within the limits of 0.5-1.0%.

**Property of certain waters with reference to their action on metals (PARR) 14.** **Potash recovery (in blast furnace industry) (GELLERT) 18.** **Use of pulverized coal at the Bunker Hill and Sullivan smelting and refining plant (RICE) 21.** **Iron protection by paint (FRIEND) 26.** **Device for sampling (RILEY) 1.** **Electric heat treatment of gun forgings (WRIGHT) 4.**

**TIEMANN, HUGH P.: Iron and Steel. (A Pocket Encyclopedia) Including Allied Industries and Sciences.** Introduction by Henry Marion Howe. 2nd Ed. Enlarged and revised. New York: McGraw-Hill Book Co. 514 pp. \$4. For review see *Eng. News-Record* 82, 781(1919); cf. *C. A.* 12, 359.

**Concentrating deslimed pulp by flotation.** RUDOLF GAHL. Can. 189,754, Apr. 22, 1919. Deslimed pulp is submitted to flotation to produce a middling product which is roasted and leached to ext. the metal. The tailings from the concn. may be similarly treated.

**Apparatus for flotation separation of sulfide ores.** T. J. PENNINGTON. U. S. 1,294,531, Feb. 18.

**Ore-separation.** A. J. MOXHAM. U. S. 1,294,519, Feb. 18. Constituents of ores of different sp. gr. are sepd. by passing the material through a bath of liquids of different sp. gr., one floating on the other, *e. g.*, a soln. of  $MnBr_2$  or  $ZnBr_2$  or  $H_3PO_4$  on  $AsBr_3$ , so that the particles of the ore are first coated with the lighter liquid and this coating weakens the bond which tends to form between the solid particles and the heavier liquid when they are immersed in the latter. The heavier liquid serves as a medium for sepn. of constituents such as Fe oxide from gang. Sepd. material is removed from the heavier liquid through the lighter liquid so that the latter serves to remove the adhering heavier liquid from the particles.

**Ore concentrator.** M. R. O'SHAUGHNESSY. Can. 187,886, Dec. 10, 1918. Structural features of an ore classifier and selector.

**Apparatus for ore concentration.** F. GROCH. Can. 189,631, Apr. 15, 1919. The air is given a spiral movement throughout the major portion of the length of the agitating chamber and a vertical movement in the upper portion. The app. is specified.

**Apparatus for ore concentration.** F. GROCH. Can. 189,505, Apr. 8, 1919. The impeller has a rotatable hollow body having axial inlet ports in its opposite walls and

a peripheral discharge opening, a partition within the body in spaced relation to the opposite walls thereof and terminating short of the periphery and dividing said hollow body into compartments and impeller blades in at least one of the compartments, the blades extending beyond the partition.

**Reducing oxide ores.** J. W. MORFAT. U. S. 1,294,514, Feb. 18. Ores which may contain Fe or other metals are reduced without fusion in any suitable furnace, and then, after reduction, excluded from contact with oxidizing gases while the temp. of the product is above the lower limit at which reoxidation might take place. The reduced material is then placed in an elec. furnace and fused in an inert or reducing atm. By reducing Fe oxides before they reach the elec. furnace, injury to the lining of the latter is avoided.

**Extracting tungsten from ores.** D. J. GILES and J. E. GILES. U. S. 1,293,402, Feb. 4. W is extd. from ores with a hot soln. of NaOH under pressure, forming sol. Na tungstate, and the latter, in dild. soln., is treated with  $\text{Ca(OH)}_2$  or  $\text{CaCl}_2$  or other sol. Ca salt to ppt. insol. Ca tungstate from the hot soln.

**Extracting tungsten from ores.** D. J. GILES and J. E. GILES. U. S. 1,293,403, Feb. 4. W ore is treated with a hot soln. of NaOH under pressure to form a soln. of Na tungstate and this soln. is sepd. from the gang and treated with  $\text{Ca(OH)}_2$  to ppt. insol. Ca compds. of Si and P. This preliminary pptn. is carried out at a relatively low temp., preferably about  $20^\circ$ , and the residual soln. is then treated with  $\text{Ca(OH)}_2$  at a higher temp., preferably about  $95^\circ$ , to ppt. Ca tungstate.

**Extracting tungsten from ores.** D. J. GILES and J. E. GILES. U. S. 1,293,404, Feb. 4. W is obtained from ore in the same manner as in the process of the preceding pat. except that HCl or other acid is used as the pptg. agent in the final step of the process, instead of  $\text{Ca(OH)}_2$ .

**Platinum recovery from ores by amalgamation.** R. E. LYONS. U. S. 1,293,828, Feb. 11. Pt is recovered from gang by amalgamation with Hg in the presence of metallic Zn and a substance such as an acid or NaOH which is capable of attacking the Zn and which serves by its reaction with the Zn to decompose the Zn amalgam formed.

**Extracting zinc from ore.** H. L. SULMAN and H. F. K. PICARD. U. S. 1,295,080, Feb. 18. Zn-bearing material is leached with 10%  $\text{H}_2\text{SO}_4$  to dissolve the Zn, the soln. is filtered off from the residue, the latter is washed to remove soln. remaining in it, milk of lime is added to the washings to ppt.  $\text{Zn(OH)}_2$  and the ppt. thus formed is added to the soln. produced from a fresh batch of Zn-bearing material by acid treatment, to neutralize the acid. The method is especially adapted for extg. Zn from roasted sulfide ore.

**Winning metals.** V. M. WEAVER. Can. 190,054, Apr. 29, 1919. Al and Si are extd. from clay by treating the clay with Cl in the presence of C to form  $\text{AlCl}_3$ ,  $\text{SiCl}_4$  and CO, the chlorides are sepd. and the metals extd. and the Cl is reused. The process is applied generally to the extn. of a metal from a substance containing it and Si and O with a halogen and a reducing agent inert to the halogen.

**Apparatus for winning metals.** V. M. WEAVER. Can. 190,055, Apr. 29, 1919. The app. comprizes in combination a furnace, a condenser connected therewith, a collecting receptacle connected with the condenser, which has a valve-controlled gas outlet, an electrolytic vat connected with the receptacle and a gas-collecting tank connected with the vat.

**Precipitation of metals from solutions.** T. B. CROWE. Can. 189,693, Apr. 15, 1919. The gases entrained in the soln. are removed by subjecting the soln. to a vacuum.

**Producing iron and steel.** W. T. STEPHENS. Can. 188,823, Feb. 25, 1919. Steel scrap mixed with fuel is heated to a temp. below the fusion pt. in a suitable furnace, then charged and compacted in a second furnace, where it is treated with the necessary fluxing agents.

**Producing pig iron.** F. H. CROCKARD. Can. 189,709, Apr. 15, 1919. Steel scrap with fluxing materials and coke is charged into a blast furnace and smelted to produce iron. Cf. C. A. 12, 1966.

**"Dry galvanizing."** D. R. WARD. U. S. 1,294,001, Feb. 11. Articles of Fe to be coated with Zn are heated in a closed chamber in a dry mixt. of pulverulent Zn particles which are coated and mixed with 25% or less of graphite.

**Hot-blast stoves.** J. I. LARIMER. Can. 189,222, Mar. 18, 1919. A multiple-pass stove has a dome-shaped top and a zigzag shaped wall sepg. adjacent passes and adapted to deflect gases without an abrupt turn.

**Four-pass hot-blast stoves.** JAS. I. LARIMER. Can. 189,223, Mar. 18, 1919. A four-pass hot-blast stove has brick checkerwork in the passes, metal checkerwork near the outlet from the last passages and has the flue opening in the several passes and in the metal checkers successively smaller.

**Producing ferrosilicon of high silicon content in blast furnaces.** JOS. E. JOHNSON, JR. Can. 189,595, Apr. 8, 1919. Ferrosilicon is produced in a blast furnace by charging the furnace with ore and fuel and supplying a blast containing O in greater proportion than in atm. air. Cf. C. A. 12, 1046.

**Alloying furnace.** F. L. MCGAHAN. Can. 189,280, Mar. 25, 1919. A furnace embodying a roasting chamber, a smelting chamber and a melting chamber specially adapted for making alloys is specified.

**Aluminium-zinc-copper alloy.** D. J. HAUSS. U. S. 1,293,426, Feb. 4. An alloy resistant to corrosion is formed of Al 72, Zn 24-25, and Cu 3 parts, substantially free from oxides. A small amt. of Mg may be used as a deoxidizing agent in forming the alloy.

**Soldering-flux.** G. P. LUCKEY. U. S. 1,293,823, Feb. 11. A soldering-flux composed of 65%  $\text{ZnCl}_2$ , 10%  $\text{NH}_4\text{Cl}$ , and 25% of a fused mixt. of KCl 56 and NaCl 44 parts is used in soldering at temps. as high as 400°.

## 10. ORGANIC CHEMISTRY.

CHAS. A. ROUILLER.

**The mutual condensation of unsaturated compounds in connection with terpenes, resins and rubber.** H. J. PRINS. Hilversum. *Chem. Weekblad* 16, 64-74(1919).—A review, with particular reference to polymerization of unsatd. compds. and the vulcanization of rubber. It is maintained that this type of reactions cannot be explained under one grouping without the aid of the valence theory and the theory of mutual activation.

JULIAN F. SMITH.

**Some naphthalene derivatives.** A. A. BOON AND JAMES OGILVIE. *Pharm. J.* 101, 129-30(1918).—In the prepn. of the mono-arsonic acid, 1,4- $\text{C}_{10}\text{H}_6(\text{NH}_2)\text{AsO}(\text{OH})_2$ , (A), by interaction of  $\text{H}_3\text{AsO}_4$  and  $\alpha\text{-C}_{10}\text{H}_7\text{NH}_2$ , an intermediate addition product,  $\text{NH}_2\text{C}_{10}\text{H}_7\cdot\text{H}_3\text{AsO}_4$ , acid  $\alpha$ -naphthylamine arsenate (B), was obtained by the authors. Mix equal wts. of  $\text{C}_{10}\text{H}_7\text{NH}_2$  and  $\text{H}_3\text{AsO}_4$  and cryst. from hot  $\text{H}_2\text{O}$ , recryst. from hot EtOH, drain and dry at 100°. (B) forms long colorless needles, m. 170°, turning dark purple at 165°. It is acid to litmus, non-deliquescent in air, but turning purple while retaining its cryst. form. It is little sol. in  $\text{Et}_2\text{O}$  and benzene, sol. in concd.  $\text{H}_2\text{SO}_4$ , but not

reppd. by  $H_2O$ . Alkalies ppt.  $C_{10}H_7NH_2$ ,  $AgNO_3$  ppts.  $Ag_3AsO_4$ . Detn. of As and N confirm its compn. Detn. of the mol. wt. by the b. p. method with abs. EtOH shows that dissociation takes place in this solvent. No other compd. seems to be formed in this reaction, even with an excess of base used. To obtain if possible the di(aminonaphthyl)arsinic acid, 2.25 parts (B) were added with vigorous stirring to 1 part of  $\alpha-C_{10}H_7NH_2$ , previously melted (about  $60^\circ$ ). The mixt. was then rapidly heated for a short time to  $200^\circ$  in an oil bath, forming a purple tar. The NaOH ext. of the tar, after distg. off the unchanged base, gave with dil.  $HNO_3$  a small amt. of (A), an amphoteric substance, persistently retaining its pink color. A concd.  $H_2SO_4$  soln. of the tar was pptd. with  $H_2O$ , forming a purple powder. When purified by repeated treatment with boiling  $H_2O$  and hot EtOH, it has the compn.  $C_{12}H_{11}NO$ , hence it is an oxidation product of the reaction. It is sparingly sol. in EtOH with violet color, sol. in  $Et_2O$ ,  $CS_2$ ,  $CHCl_3$  and  $AcOEt$ , insol. in dil. acids and alkalies, not reduced by  $SO_2$ .

S. WALDBOTT.

The constitution of dynopinacone and its derivatives. M. DELACRE. *Ann. chim.* 10, 101-37(1918).—This is the fifth of a series of publications on this subject. The first (C. A. 8, 3420) and second (C. A. 10, 2580) have appeared; the third and fourth have been left in occupied territory and cannot be recovered before the end of the war. The substances under investigation are divided into three classes: (A) Dynopinacolines, further divided into albo-dyp. and luteo-dyp., (B) photodynopinacolines; (C) dynopinacones, of which six are known. Alkalies convert all of the latter into albo-dynopinacolines. AcOH converts the homo-dynopinacones into the homo-dynopinacolines. Sunlight converts albo-dynopinacolines into photo-dynopinacolines- $\beta$ . The relationships are shown by the scheme:

Structural formulas and an exhaustive discussion are included. JAMES F. COUCH.

Alkaloids of *Holarhena conchensis*, Stapf. FRANK L. PYMAN. *J. Chem. Soc.* 115, 163-6(1919).—In an examn. of this plant in 1913, the author isolated a new base *holarrheminine*,  $C_{24}H_{34}ON_2$ , together with the alkaloid conessine, which had been obtained previously by several authors from other species of *Holarhena*. The physiol. action of these 2 alkaloids was studied by Burn (cf. C. A. 9, 659), who found that while they had a local anesthetic action, this property was of no practical value on account of the local necrosis produced on subcutaneous injection. The observations made by P. on conessine are for the most part in agreement with the recent work of Giemsa and Halberkann (*Arch. Pharm.* 256, 201(1918)), and confirm the formula  $C_{24}H_{34}N_2$  supported by these authors, not that— $C_{28}H_{38}N_2$ —put forward by Ulrici (*Arch. Pharm.* 256, 57(1918)). Giemsa and Halberkann's view that conessine contains 2 dialkylamino groups is not shared by P., who found conessine to contain only 3 alkyl groups (no doubt Me) attached to the N atom. Moreover, Polstorff and Schirmer (*Ber.* 19, 84(1886)) showed that conessine dimethohydroxide yields, on heating, a cryst. base, to-

gether with "ammonia" (doubtless  $\text{NMe}_3$ ). It is therefore probable that conessine contains an *N*-Me group forming a link in a heterocyclic ring, to which a side-chain bearing a  $\text{NMe}_2$  group is attached. Holarrhenine resembles conessine in containing 3 *N*-alkyl groups. It yields a monoacetyl derivative,  $\text{C}_{24}\text{H}_{40}\text{O}_2\text{N}_3$ , which is diacidic, whence it follows that holarrhenine contains a OH group. Conessine hydrogen oxalate,  $\text{C}_{24}\text{H}_{40}\text{N}_3 \cdot 2\text{C}_2\text{H}_2\text{O}_4$ , forms prisms m.  $280^\circ$  (decompn.). The free base gave the constants:  $\alpha_D -0.28^\circ$ ,  $c = 7.268$ ,  $l = 2$  dcm.,  $[\alpha]_D -1.90^\circ$ . Holarrhenine,  $\text{C}_{24}\text{H}_{38}\text{ON}_3$ , silky needles, m.  $197-8^\circ$ . The sp. rotatory power in  $\text{CHCl}_3$  is:  $\alpha_D -0.75^\circ$ ,  $c = 5.248$ ,  $l = 2$  dcm.,  $[\alpha]_D -7.1^\circ$ . The hydrobromide,  $\text{C}_{24}\text{H}_{38}\text{ON}_3 \cdot 2\text{HBr} \cdot 3\text{H}_2\text{O}$ , flat needles, m.  $265-8^\circ$ , loses  $\text{H}_2\text{O}$  of crystn. at  $100^\circ$ . Acetylholarrhenine,  $\text{C}_{26}\text{H}_{40}\text{O}_2\text{N}_3$ , oblong plates, m.  $180^\circ$ . W. O. E.

Lactone acids which were derived from anethole. J. TAKEDA AND S. KURODA. *Yakugaku-Zasshi* (J. Pharm. Soc. Japan) No. 443, 1-20(1919).—The reaction products of 1 mol. of anethole bromohydrin obtained by the action of  $\text{H}_2\text{O}-\text{Me}_2\text{CO}$  on dibromoanethole (*Ber.* 38, 3470(1905)) and 1 mol. of  $\text{CHNa}(\text{CO}_2\text{Et})_3$ , sapond. with alc. KOH, and allowed to stand for 1 month, is  $\gamma$ -*p*-methoxyphenyl- $\gamma$ -methylbutyrolactone- $\alpha$ -carboxylic acid,  $\text{C}_{12}\text{H}_{14}\text{O}_6$ , which seps. from the soln. in white crystals, recrystd. from 20% alc., m.  $119^\circ$ , insol. in ligroin and  $\text{CS}_2$ . The formation of the acid is represented as follows:  $\text{MeOC}_6\text{H}_4\text{CH}(\text{OH})\text{CHBrMe} + \text{NaCH}(\text{CO}_2\text{Et})_3 \rightarrow \text{MeOC}_6\text{H}_4\text{CH}(\text{OH})\text{CHMe} \cdot \text{CH}(\text{CO}_2\text{H})_2 \rightarrow$

. From the mother liquor anisace-

tone was also isolated. However, by the interaction of 1 mol. dibromoanethole and 2 mols. of the ether,  $\beta$ -*p*-methoxyphenyl- $\gamma$ -methylbutyrolactone- $\alpha$ -carboxylic acid, m.  $161^\circ$ , was obtained. The mechanism of the formation of the  $\beta$ -lactone acid, is explained by assuming that the Br in the  $\alpha$ -position of dibromoanethole is more reactive than that in the  $\beta$ -position (Pond, *J. Am. Chem. Soc.* 24, 327; 25, 262; Höring, *Ber.* 38, 3446), T. and K. have observed that 2-*p*-methoxyphenyl-3-methyltrimethylenecarboxylic acid,  $\text{C}_{12}\text{H}_{14}\text{O}_6$ , m.  $134^\circ$ , was formed simultaneously with the  $\beta$ -lactone acid; it is sol. in ligroin and  $\text{CS}_2$  and crystals in silky needles from 50% alc. On heating the  $\beta$ -lactone acid to its m. p., it decomps. into  $\text{CO}_2$  and  $\beta$ -*p*-methoxyphenyl- $\gamma$ -methylbutyrolactone,  $\text{C}_{12}\text{H}_{14}\text{O}_5$ , m.  $90^\circ$ , soluble in hot  $\text{H}_2\text{O}$  and ligroin. The lactone acid by the action of HI yields  $\beta$ -*p*-hydroxyphenyl- $\gamma$ -methylbutyrolactone- $\alpha$ -carboxylic acid,  $\text{C}_{12}\text{H}_{12}\text{O}_6$ , m.  $178^\circ$ , insol. in ligroin, sol. in cold  $\text{H}_2\text{O}$ ,  $\text{C}_6\text{H}_6$ ,  $\text{Et}_2\text{O}$ ,  $\text{CHCl}_3$ , from which  $\beta$ -*p*-acetoxyphenyl- $\gamma$ -methylbutyrolactone,  $\text{C}_{12}\text{H}_{14}\text{O}_6$ , m.  $81^\circ$ , and  $\beta$ -*p*-hydroxyphenyl- $\gamma$ -methylbutyrolactone,  $\text{C}_{11}\text{H}_{12}\text{O}_5$ , m.  $109^\circ$ , were obtained by the action of  $\text{Ac}_2\text{O}$  and by heating, resp. S. KOMATSU.

Urushiol, the main constituent of Japanese lac. VII. R. MAJIMA, R. TAHARA, G. TAKAYAMA, T. WATANABE AND Y. OKAZAKI. *Tokyo Kwagaku Kwaishi* (J. Tokyo Chem. Soc.) 40, 1-41(1919).—The present study on the oxidation of the Me ether and Ac derivs. of urushiol by  $\text{O}_3$  and  $\text{KMnO}_4$ , contributes to the knowledge of the constitution of urushiol. Tahara has prepd. diacetylurushiol,  $b_0$ ,  $212-20^\circ$ , from crude urushiol and  $\text{Ac}_2\text{O}$ , and purified it by fractional distn. *in vacuo*. The ozonide of the ester prepd. by passing ozonized  $\text{O}$  (3 %) into the  $\text{CHCl}_3$  soln., was decompd. by hot  $\text{H}_2\text{O}$ , yielding  $\text{AcH}$ ,  $\text{Me}(\text{CH}_2)_3\text{CHO}$ ,  $\text{Me}(\text{CH}_2)_3\text{CO}_2\text{H}$ , azelaic acid and a substance,  $\text{C}_{11}\text{H}_{20}\text{O}_6$ ,  $b_1$   $205-7^\circ$ , containing 2 Ac groups in the mol. and giving azelaic acid on oxidation with  $\text{KMnO}_4$ . Diacetylhydrouushiol, m.  $51^\circ$ , was isolated from the soln. of ozonized diacetylurushiol, and its compn. confirmed by analysis and mol. wt. detn. Monoacetylhydrouushiol methyl ether, m.  $45-6^\circ$ , was also isolated by Takayama from the filtrate from acetylurushiol methyl ether ozonide, pptd. by adding petr. ether to its chloroform soln. These facts lead the authors to the notion that crude urushiol contains hydrouushiol. Takayama has prepd. pure acetylurushiol methyl ether from the monomethyl ether

purified by fractional distn. *in vacuo* and  $\text{Ac}_2\text{O}$  and transformed into its ozonide. The ozonide purified by pptn. was decompd. by hot  $\text{H}_2\text{O}$ , yielding  $\text{Me}(\text{CH}_2)_6\text{CHO}$ ,  $\text{Me}(\text{CH}_2)_6\text{CO}_2\text{H}$ ,  $\text{AcO}(\text{MeO})\text{C}_6\text{H}_5(\text{CH}_2)_6\text{CHO}$ ,  $b_{78}$ , 190–210°, and a cryst. substance,  $\text{MeO}(\text{OH})\text{C}_6\text{H}_5(\text{CH}_2)_6\text{CO}_2\text{H}$ , m. 49–50°, needles from petr. ether, sol. in alc.  $\text{Et}_2\text{O}$ ,  $\text{Me}_2\text{CO}$ ,  $\text{CHCl}_3$ ,  $\text{C}_6\text{H}_6$  and  $\text{AcOEt}$ . On the other hand, W. has succeeded in obtaining  $\text{Me}(\text{CH}_2)_6\text{CHO}$ ,  $\text{HCO}_2\text{H}$ , adipic acid,  $(\text{CO}_2\text{H})_2$ ,  $(\text{MeO})_2\text{C}_6\text{H}_5(\text{CH}_2)_6\text{CO}_2\text{H}(?)$  and veratrol-*o*-carboxylic acid, m. 121–2°, from the oxidation product obtained by the action of  $\text{KMnO}_4$  on an emulsion of urushiol dimethyl ether. The isolation of both veratrol-*o*-carboxylic acid and  $\text{MeO}(\text{OH})\text{C}_6\text{H}_5(\text{CH}_2)_6\text{CO}_2\text{H}$  from urushiol by oxidation, gives strong support to the constitution of urushiol proposed by M. W. obtained  $\text{AcH}$ ,  $\text{Me}(\text{CH}_2)_6\text{CHO}$  and  $\text{HCO}_2\text{H}$  from the oxidation product of urushiol dimethyl ether by  $\text{O}_3$ . However, repeating the same expt. with pure ether,  $\text{HCHO}$ ,  $\text{Me}(\text{CH}_2)_6\text{CHO}$ ,  $\text{CO}_2$  and  $\text{HCO}_2\text{H}$  were obtained but not  $\text{AcH}$ . According to the results of the oxidation of the derivs. of urushiol by  $\text{O}_3$  and  $\text{KMnO}_4$ , urushiol,  $(\text{OH})_2\text{C}_6\text{H}_5\text{C}_{11}\text{H}_{27}$ , is probably a mixt. of the following substances:  $(\text{HO})_2\text{C}_6\text{H}_5(\text{CH}_2)_7\text{CH}:\text{CH}(\text{CH}_2)_6\text{Me}$ ,  $(\text{HO})_2\text{C}_6\text{H}_5(\text{CH}_2)_7\text{CH}:\text{CH}(\text{CH}_2)_4\text{CHCH}_3$ , or  $(\text{OH})_2\text{C}_6\text{H}_5(\text{CH}_2)_7\text{CH}:\text{CHC}_6\text{H}_5\text{CHCH}_3$ . The different behavior of Br toward urushiol dimethyl ether and stearic acid observed by W. and O, also supports the view that urushiol contains double bonds in its mol. Studying the fraction  $b_{11}$  130–137° of urushiol dimethyl ether, an unsatd. hydrocarbon named *urusene* was isolated by Takayama. The results of its analysis, mol. wt. detn., and its chem. properties agree with the formula  $\text{C}_{14}\text{H}_{28}$  or  $\text{C}_{14}\text{H}_{30}$ . S. KOMATSU.

**Preparation of certain organic salts of tellurium.** AARON M. HAGEMAN. *J. Am. Chem. Soc.* 41, 342–6(1919).— $\text{Te}(\text{HC}_4\text{H}_9\text{O}_6)_4$  is best prepd. by a prolonged heating of  $\text{TeO}_3$  with a satd. soln. of tartaric acid at 70° until *all* the  $\text{H}_2\text{C}_4\text{H}_4\text{O}_6$  is used up. It is impossible to sep.  $\text{Te}(\text{HC}_4\text{H}_9\text{O}_6)_4$  from  $\text{H}_2\text{C}_4\text{H}_4\text{O}_6$  by crystn. because they have nearly the same soly. Boiling the salt causes a slow but complete sepn. of Te. *Tellurium acid citrate*,  $\text{Te}(\text{HC}_4\text{H}_9\text{O}_7)_3$  is produced by the action of a concd. soln. of citric acid on  $\text{TeO}_3$ . It crysts. in white, opaque, radiating crystals, withstands boiling temps. without reduction, and may be sepd. from the free acid by fractional crystn. Succinic acid does not attack  $\text{TeO}_3$ . Oxalic, lactic, malic, and gallic acids hold appreciable amts. of  $\text{TeO}_3$  in soln., but it was impossible to sep. a cryst. compd. of Te with any of these acids. The existence of an oleate or stearate of Te is shown to be doubtful. Cf. C. A. 13, 936. R. H. LOMBARD.

**Total synthesis of linalool.** L. RUZICKA AND V. FERNANDEZ. *Helvetica Chim. Acta* 2, 182–8(1919).—As is perhaps known, all methods hitherto employed in the artificial prepn. of linalool are based upon reactions involving mol. rearrangement. In the present investigation this alc. was obtained by recourse to the reaction discovered by Nef (cf. *Ann.* 308, 264) whereby condensations are effected between ketones and compds. of Na acetylide. Thus, on treating methylheptenone in abs.  $\text{Et}_2\text{O}$  with Na amide followed by satn. with  $\text{C}_6\text{H}_6$ , *dehydrolinalool*,  $\text{C}_{10}\text{H}_{16}\text{O}$ , a watery liquid,  $b_{11}$  91–3°, (*phenylurethan*,  $\text{C}_{17}\text{H}_{21}\text{O}_2\text{N}$ , fine, brilliant needles, m. 88°) resulted. On reduction in moistened  $\text{Et}_2\text{O}$  with Na, linalool,  $b_{11}$  86–8° and  $b_{70}$  194–7°, was obtained, having  $d_{18}$  0.8649 and 0.8654, and yielding a phenylurethan, m. 63–5°. This synthesis corroborates the formula for linalool,  $\text{Me}_3\text{C}:\text{CHCH}_2\text{CH}_2\text{CMe}(\text{OH})\text{CH}:\text{CH}_2$ , as advocated by Tiemann and Semmler (*Ber.* 28, 2126). W. O. E.

**A chart of organic chemistry, aliphatic series.** ALEXANDER LOWY. *Science* 49, 314(1919).—The chart is for teaching purposes. E. J. C.

**II-10-Bromophenanthrene-3(or 6)-sulfonic acid.** HÅKAN SANDQVIST. *Ann.* 417, 1–16(1918).—See C. A. 12, 807. E. H.

**I-10-Chlorophenanthrene-3(or 6)-sulfonic acid and 10-chlorophenanthrene.**  
**HÅKAN SANDQVIST.** *Ann.* 417, 17-33(1918).—See C. A. 12, 807. E. H.

Preparation of organic chlorostannites and -stannates (DRUCE) 6. Electrolysis of fused sodium and potassium amides (WÖHLER, STANG-LUND) 4. Distillation of ovalbumin (PICTET, CRAMER) 11A. Still for "mustard gas" (STREETER) 1. Glyceryl methyl ether dinitrate (JONES) 24.

**Chlorinating naphthalene.** K. BROWN. U. S. 1,294,230, Feb. 11. The pat. relates to an app. in which  $C_{10}H_8$  is chlorinated by the action of a current of Cl passed through a series of steam-jacketed pots in which the  $C_{10}H_8$  is held.

**Chlorinating hydrocarbons of the paraffin series.** H. T. BOYD. U. S. 1,293,012, Feb. 4. Chlorination of hydrocarbons of the paraffin series such as pentane is carried out in 2 stages. In the first stage, the hydrocarbon is treated in the liquid state with Cl and the vapors given off from this stage (which consist almost wholly of unconverted hydrocarbon, Cl and HCl comparatively free from chlorinated hydrocarbons) are then further treated with Cl in a sep. reaction vessel. The method is designed to obtain a max. yield of monochloro derivs. and may be carried out continuously in an app. which is illustrated and described in the pat. The satn. of monochloro compds. in both the liquid-phase and vapor-phase chlorinations is preferably kept below 25% by suitable regulation of the supply of Cl and hydrocarbon and of the rate at which the products are fed from the chlorination chamber to a still wherein they are fractionated, to prevent, so far as possible, the formation of di- and trichloro compds.

**Purifying anthraquinone.** H. F. LEWIS and H. D. GIBBS. U. S. 1,293,610, Feb. 4. Crude anthraquinone is freed from impurities such as anthracene, by treatment, while in the solid state, with finely divided Fe and a hot alk. soln. such as alc.,  $H_2O$  and NaOH, followed by filtration and reoxidation of the reduced anthraquinone. The pat. is dedicated to the public for free use.

**Acetone and alcohol by fermentation.** J. H. NORTROP. U. S. 1,293,172, Feb. 4. *Bacillus aceto-ethylicum* is used for producing acetone and alc. by the fermentation of carbohydrates. The following yields of acetone are obtained from various materials fermented: galactose 4-5%, maltose 6-7%, mannose 6-7%, raffinose 8-10%, *d*-arabinose 6-7%, starch 8-10%, beet molasses 8-10%, potatoes 2-4%, dextrin 6-7%, dextrose 9-10%, levulose 8-10%, xylose 4-5%, sucrose 8-9%, corn 10-13%, corn cobs 1-5%, horse chestnuts 7-8%. In fermenting these materials there is simultaneously produced a yield of alc. usually averaging about 3-5 times the amt. of the acetone formed. Glycerol, fermented with *B. aceto-ethylicum*, yields 40-43% alc. The materials to be fermented may be formed into a mash with 10-50 times their weight of  $H_2O$ , a small amt. of nitrogenous material and a "buffer substance" such as  $CaCO_3$  or Na phosphate, which is added after preliminary sterilization, to prevent the mash from becoming acid. The charge thus prepd. is allowed to ferment for 4-8 days, and after the products are drawn off from the fermentation vessel to a still, a fresh charge is placed in the fermenting vessel and allowed to ferment by the action of the bacilli adhering to the walls of the vessel. This second and succeeding fermentations are somewhat more rapid than the first fermentation, being completed in 40-60 hrs. In fermenting molasses, marble chips may be placed in the fermenting vessel to serve instead of any other "buffer substance."

**Camphylcarbinol.** HANS RUPE. Ger. 307,357, 1918. Hydroxymethylene-camphor only suffers reduction at the ethylenic bond when reduced by H in the presence of finely divided Ni or Co in alc., aq.-alc., or HOAc soln., or as normal alk. salt in

aq. soln.; camphylcarbinol, which is thus produced, is a colorless, odorless oil, b. 142-3° at 10 mm.,  $d_4^{20}$  1.0502.

4-Sulfoaminobenzene-2-carboxylic (6-amino-*m*-sulfobenzoic) acid. BAYER & Co. Ger. 307,284, addition to 296,941, 1918 (C. A. 13, 322). 6-Amino-*m*-sulfobenzoic acid is conveniently prepd. by the action of mol. amts. of chlorosulfonic acid and anthranilic acid dissolved in  $H_2SO_4$  monohydrate. The mixt. is slowly heated to 90-100°, and subsequently to 130-140° after evolution of HCl has ceased. Under these conditions, the monohydrate has practically no sulfonating action.

Ethyl acetate from acetaldehyde. FARBERWERKE VORM. M. L. & B. Ger. 308,043, 1918. The process depends on the use of a soln. of  $Al(OEt)_3$ , which contains at the most only traces of halogen compds., in an org. solvent of high b. p., such as solvent naphtha. With such solns., which allow the most favorable temp. to be readily maintained, the yield of practically pure  $EtOAc$  exceeds 85% of that theoretically possible; at the same time, the duration of the action is considerably decreased, and the consumption of  $Al(OEt)_3$  is reduced to 3-5% of the  $CH_3CHO$ .

## II. BIOLOGICAL CHEMISTRY.

HATTIE L. HEFT AND WILLIAM J. GIES.

### A. GENERAL.

FRANK P. UNDERHILL.

Distillation of ovalbumin under diminished pressure. A. PICTET AND M. CRAMER. *Helvetica Chim. Acta* 2, 188-95 (1919).—The operation was carried out in a Cu retort under a pressure of 20-22 mm. with a charge of 4 kg. of commercial egg albumin. With a gradual increase of temp. ranging from 70 to 350°, the products obtained were  $H_2O$  30%,  $H_2O$ -sol. and -insol. org. substances 15%, coke 32%, gases and loss 23%. The org. substances were entirely sol. in  $Et_2O$ , being subsequently sepd. therefrom by successive treatment into acid, basic and neutral portions. Among the acids identified were  $AcOH$ ,  $EtCO_2H$ , butyric and succinic acids. The basic portion yielded on distn. fractions possessing the odor characteristics of the pyrrolines. One of the fractions appeared to be homogeneous, giving an abundant ppt. with picric acid (yellow needles m. 185°), and is tentatively regarded as being the primary base (*dihydroaniline*, and

having the constitution:

This formula would seem to explain the

presence of aniline and benzene in certain tars (*d'huile animale de Dippel*). The neutral substances arising from the distn. yielded on fractionation for the most part crystalline products, notably isobutylacetamide, m. 120°, which result leads the author to the following reasoning: (1) Weidel and Ciamician have identified isobutylacetoneitrile as one of the main constituents of animal oil (*l'huile animale*), but they attribute its formation to a reaction of  $NH_3$  on fats contained in the animal tissues. The present work indicates that it is indeed a product of the decompn. of albumin, but a secondary one; the primary product is the amide which can be isolated under reduced pressure, but which under a more elevated temp. and pressure loses a mol. of  $H_2O$ . (2) If one compares the formula of isobutylacetamide,  $Me_2CHCH_2CH_2CONH_2$ , with that of leucine,  $Me_2CHCH_2CH(NH_2)CO_2H$ , which forms the most abundant product in the hydrolytic decompn. of proteins, one finds a certain analogy. While these 2 substances are derived one from the other, it appears probable that both have their rise in the same

atomic grouping. Such common source is readily explained if the grouping in question is constituted, as the investigations of E. Fischer have rendered extremely probable, in a diketopiperazine-like combination:

If the ring is split at the line *ab* by hydrolysis or at *cd* by heat, either leucine or isobutyl acetamide would result. On washing the crystals of isobutylacetamide with petr. ether, there resulted on evapn. an oily residue in which was identified both acet- and propionamide. Among the higher boiling fractions of neutral products indole was detected (by its picrate).

W. O. E.

**Influence of neutral salts on the action of salivary amylase.** J. T. GROLL. *Arch. néerland. physiol.* 2, 516-20(1918); *Physiol. Abstracts* 3, 407(1918).—Study was made of the influence of various neutral salts on the activity of ptyalin (salivary amylase), taking the first appearance of the red color or erythro-dextrin as the end-point of the reaction. The influence of anions was greater than that of cations. With the chlorides the accelerating action of the cations was:  $\text{Na} < \text{NH}_4 < \text{K}$  and  $\text{Sr} < \text{Ba} < \text{Mg} < \text{Ca}$ ; this corresponded with the series as found in colloid chemistry. Of the anions, halogen activated, sulfates and nitrates inhibited; the series corresponded but partially with that of colloid chemistry. Neutral salts apparently influence other factors than the degree of dispersion of the enzyme.

JOSEPH S. HEPBURN.

**Studies on Pikelharing's pepsin. IV.** W. E. RINGER. *Arch. néerland. physiol.* 2, 571-93(1918); *Physiol. Abstracts* 3, 408(1918).—Pepsin is always negatively charged, and has no isoelectric point, thereby differing from other albuminoid substances. Pure pepsin is combined with an albumin-like substance which travels to the cathode. The action of pepsin on albumin is governed at first by the amt. of swelling of the latter; sulfates, etc., inhibit proteolysis by hindering this swelling or imbibition. The elec. charge of the albumin is closely related to the degree of imbibition, and probably is the determining factor during the later stages of digestion, since an opposite charge favors the combination of enzyme and substrate. The degree of digestion was detd. by pptn. with tannic acid in the presence of a definite concn. of salts, and detn. of non-pptd. N in the filtrate. Albumin of dialyzed serum was used; the H-ion concn. of the soln. was detd. during digestion; the control was a soln. of the same compn. containing inactive pepsin. "Similar expts. with hetero-, deutero-, and proto-albumose showed that the plateau representing max. activity was much more prolonged when the recent products of demolition were concerned (albumose v. albumin). The plateau was reached with a lower acidity and the ascent of the curve was much slower; the condition was more pronounced in deutero- than in proto- or heteroalbumose." The ferrocyanogen anion only combines with the positive charged albumin ion; therefore addition of  $\text{K}_4\text{FeC}_6\text{N}_6$  inhibited the proteolysis of dialyzed horse serum by pepsin;  $\text{KCl}$  and  $\text{K}_2\text{SO}_4$  exerted a slight inhibiting action only in higher concns.; these results support the theory that the charge on the substrate is important in the action of pepsin.

JOSEPH S. HEPBURN.

**Enzymes and surface action.** W. M. BAYLISS. *Arch. néerland. physiol.* 2, 621-4(1918); *Physiol. Abstracts* 3, 406-7(1918).—The following expts. were based on the hypothesis that the action of enzymes as heterogeneous catalysts consists in the condensation on their surfaces by adsorption of the constituents of the reacting systems

including water. The enzyme used was soy bean urease. Saponin exerted a retarding action, probably due to its degree of adsorption, and to its ability to replace the substrate on the surface of the enzyme. From a soln. containing saponin and urea, charcoal adsorbed saponin to the exclusion of a large amt. of urea. Saponin retarded the cleavage of urea by urease as was shown by the change in elec. cond.; but hydrolysis attained the same point in 24 hrs. in both the presence and the absence of saponin. Both surface energy and adsorption have a negative temp. coeff.; the inhibiting effect of saponin was greater at 0° than at 40°, hence was due to adsorption. The temp. coeff. of the reaction was also changed by saponin.

Rudolph Kobert. ERNST SIEBURG. *Chem. Ztg.* 43, 25-6(1919).—Obituary.

E. H.

**Mucins and mucoids.** P. A. LEVENE AND J. LÓPEZ-SUÁREZ. Rockefeller Inst. *J. Biol. Chem.* 36, 105-26(1918).—There is a chem. distinction between the two types of conjugated sulfuric acids obtained from mucins and mucoids of different origins; the one, chondroitin- $H_2SO_4$ , contains the nitrogenous hexose, chondrosamine, and the other, mucoitin- $H_2SO_4$ , yields chitosamine. The former is found in the mucoids isolated from cartilage, tendons, aorta and sclera and the latter from (A) funis mucin, humor vitreous, and cornea and (B) mucin of gastric mucosa, serum mucoid, ovomucoid, and ovarian cysts. Chondroitin- $H_2SO_4$  is comparatively resistant toward hydrolytic agents and can be obtained in a fair degree of purity but mucoitin- $H_2SO_4$  is always mixed with mucoitin when prepd. free from protein. The intermediary substance, chondrosin, is readily prepared in a pure state whereas mucosin is so labile that it is almost completely hydrolyzed under conditions which permit the prepn. of chondrosin. When mucoitin- $H_2SO_4$  is subjected to milder hydrolysis the mucosin formed contains undecompd. mucoitin. Differences were observed between the different members of the mucoitin- $H_2SO_4$  group and it is probable that the acids of this group belong to 2 types, the one being obtained from the substances in group (A) and the second from group (B). The first is characterized by being pptd. by comparatively small amts. of glacial AcOH as a gelatinous ppt. and by the readiness with which it forms an insol. Ba salt, very sparingly sol. in  $H_2O$  but readily sol. in the presence of acetates. The second type forms a Ba salt of greater soly., requires a large excess of glacial AcOH for pptn. and forms a flocculent rather than a gelatinous ppt. When  $H_2SO_4$  is removed from mucoitin- $H_2SO_4$  a substance is formed which is analogous to chondroitin. It is non-reducing and does not contain free amino groups. It forms mucosin on hydrolysis, which is a disaccharide composed of glucuronic acid and chitosamine. Mucoitin, like chondroitin, contains one acetyl group to each mol. of chitosamine, glucuronic and sulfuric acids. The glucuronic acid could be identified with a greater degree of exactness in the acids of the funis mucin type. A suggested graphic formula for mucoitin- $H_2SO_4$  is given.

A. P. LOTHROP.

**The stability of esterase in ground liver preserved in glycerol.** J. P. SIMONDS. *Am. J. Physiol.* 48, 141-5(1919).—Ground liver preserved in glycerol may retain its esterolytic power unimpaired for periods up to 24 months at least. In some cases there is even an increase in the activity of the clear filtered ext., due probably to autolysis of the liver cells with liberation of the esterase. In some cases a diminution of esterase might have been due to the large amt. of bile present (e. g., in livers from P-poisoned dogs).

J. F. LYMAN.

**Stimulation by the outward diffusion of an electrolyte.** W. D. ZORTHOUD. *Am. J. Physiol.* 48, 161-70(1919).—Expts. reported are interpreted to show that  $BaCl_2$  does not stimulate muscle by its mere presence in the irritable structure but rather by its active diffusion into or out of the tissue. The stimulating effect of  $BaCl_2$  is counteracted by KCl,  $NH_4Cl$ ,  $CaCl_2$  and  $MgCl_2$ . NaCl increases the effect of  $BaCl_2$ .

J. F. L.

**The catalytic power of blood and solid tissue.** F. C. BRIGHT. *Am. J. Physiol.* 48, 171-91(1919).—Since the catalase of the blood in the same species under the same conditions varies enormously (100 to 1000%) it is believed that Burge and others are unjustified in using catalase values of the blood as a measure of oxidation in the animal. Thyroid feeding produced in cats a slight fall in blood catalase as opposed to the increase reported by Burge. There was no parallelism between activity and blood catalase; indeed several very active animals were noted with very low blood catalase. Satisfactory determinations of catalase in solid tissues cannot be made by any method yet described owing to the slow and long-continued evolution of O from  $H_2O_2$  in the presence of solid organs. Catalase power of the blood is confined to the corpuscles and is not influenced by the O-carrying power of the blood. Ether anesthesia causes a slight increase in blood catalase. J. F. LYMAN.

**The function of the nucleus of the living cell.** VERNON LYNCH. *Am. J. Physiol.* 48, 258-83(1919).—An ameba deprived of its nucleus may exhibit normal movements. Such an ameba lives only as long as a normal starving ameba. It is benefitted slightly by the addition of dextrose to the nutrient media, but is injured by simple N compds., such as urea, while the normal organism appears to utilize urea N in synthesizing protoplasm. The enucleated cell may move, respire, digest, respond to stimuli and exhibit any activity which is dependent solely upon catabolic or destructive processes of protoplasm. The group of phenomena which it never shows are those of growth and of regeneration and division, *vis.*, those depending upon organic synthesis. There is no evidence that oxidation is interfered with in enucleated cells. J. F. LYMAN.

**Decrease of permeability and antagonistic effects caused by bile salts.** W. J. V. OSTERHOUT. *J. Gen. Physiology* 1, 405-8(1919).—Na taurocholate produced a decrease in permeability and antagonized the effect of NaCl which normally produces an increase in permeability. This confirms the hypothesis that antagonistic relations as regards permeability can be predicted from a study of the permeability of pure substances. The plant, *Laminaria*, was largely used in these expts.

CHAS. H. RICHARDSON.

**A comparison of permeability in plant and animal cells.** W. J. V. OSTERHOUT. *J. Gen. Physiology* 1, 409-13(1919).—The plant tissue chiefly used was from *Laminaria*; the animal tissue was the skin of the frog, *Rana pipiens*. Quant. studies were made on the permeability of these tissues in sea water solns. to which were added  $CaCl_2$ , NaCl,  $LaNO_3$ ,  $MgCl_2$ , HCl, KCl,  $Et_2O$ ,  $CHCl_3$ ,  $CCl_4CH(OH)$ , or EtOH with the result that a striking agreement was found in certain important aspects of permeability, antagonism, injury, recovery and death.

CHAS. H. RICHARDSON.

**Bioelements: The chemical elements of living matter.** INGO W. D. HACKH. *J. Gen. Physiology* 1, 429-33(1919).—Of the 87 known elements, 34 have been found to enter into living matter. Seventeen of these seem to be essential to life and not more than 4 constitute 97-99% of the living organism. The majority of the bioelements are of low atomic wt., belonging to the first 2 periods of the periodic system. Oxygen is the only one which enters into the living organism as an element; all others occur only in compounds. The 1st 16 elements found in the mammal (man) named in the descending order of their percentage occurrence are: O, C, H, N, Ca, P, K, S, Cl, Na, Mg, I, F, Fe, Br, and Al. Those for the plant (Gymnosperm) are: C, O, H, Al, Si, S, Fe, N, Ca, K, P, Mg, Cl, Na, F, and Mn. Ti occurs in traces in nearly all plants; its physiological functions are little known. From 60 to 80% of the known elements are of a more or less poisonous character to organisms. The order of the occurrence of elements in the gaseous, liquid and solid spheres is given for comparison.

CHAS. H. RICHARDSON.

## B. METHODS AND APPARATUS.

STANLEY R. BENEDICT.

Tests of a new pregnancy reaction, similar to that of Kottmann. PAUL HÜSSY. *Cor.-bl. f. Schweiz. Aerzte, Basel* 48, 733-42(1918); *Abstracts of Bacteriology* 2, 254.—The technic of the reaction is much the same as with the Fe-placenta method of Kottmann, although H. thinks that the modified reaction employing a Cu-placenta compd. is more reliable. E. J. C.

The question of the preparation of Teichmann hemin crystals. N. BOKARIUS. *Viertelg. f. gericht. Med.* 55, 255-9(1918); *Physiol. Abstracts* 3, 501.—By adjusting the proportion between the AcOH and a concd. aq. soln. of NaCl as laid down fully in the paper, hemin crystals of large size can be rapidly obtained. E. J. C.

Medico-legal study of adrenaline content of suprarenals. O. SAMPARIO. *Brasil-Medico* 32, 81(1918); *Physiol. Abstracts* 3, 386.—Tests for detg. whether death has occurred suddenly or not. E. J. C.

Determination of the nitrogen-methyl in the blood. A. KOSSEL AND S. EDL-BACHER. *Arch. nêerland. physiol.* 2, 625-8(1918); *Physiol. Abstracts* 3, 427(1918).—E.'s micro-method for detn. of N-bound alkyl was found applicable for detn. of the N-Me of the blood, and was used in a series of normal and pathological cases. A micro-Kjeldahl method was used for the detn. of the N. JOSEPH S. HEPBURN.

Phenolphthalin as a test for occult blood in feces. S. YAOITA AND M. HINO. *Chugai Iji Shimpô* 903, 1306-10(1917); *Jap. Med. Literature* 4, 9-10(1919).—The phenolphthalin is prepd. from phenolphthalein by use of Zn powder and aq. soln. of KOH. This test for occult blood is sensitive to 1 part in 1,000,000, when an AcOH-alc. ext. of the feces is used. JOSEPH S. HEPBURN.

New experimental method for the qualitative and approximately quantitative determination of protein in cerebrospinal fluid. PAUL KIRCHBERG. *Deut. med. Wochschr.* 44, 657(1918).—A pathologic increased protein content of the cerebrospinal fluid is detected qualitatively by thoroughly mixing several drops of the fluid and an equal vol. of 0.5% aq. soln. of thiosalicylic acid in a small tube; formation of a cloud reveals the pathologic increase. For the quant. detn., 2 cc. of the cerebrospinal fluid and 1 cc. of 1% aq. soln. of thiosalicylic acid are mixed in a suitable centrifuge tube and permitted to stand for 15 min.; an opalescence is normal; the tube is then subjected to centrifugation until the ppt. attains a constant vol.; 20 min. is the usual time required; an opalescence of the supernatant liquid is without significance. By comparisons with ppts. obtained by this procedure from known concns. of sera, the % of protein can be detd. If Nissl tubes be used in the centrifuge, a ppt. to the precipitate level (Bodensatzhöhe) corresponds to the normal content of 0.02% protein, a ppt. to the half-division to 0.04% protein (pathologic increase). JOSEPH S. HEPBURN.

Clinical importance of fecal examination in pediatric practice. C. S. RAUE. *Hahnemannian Monthly* 54, 212-9(1919).—Chem. methods for the examn. of feces are described; and the clinical interpretation of the results is discussed. J. S. H.

Estimation of calcium in blood. S. PERN. *Proc. Roy. Soc. Victoria* 30, 137-8(1918); *Physiol. Abstracts* 3, 427(1918).—The blood (1 cc.) is carefully ashed, AcOH is added, and the soln. is filtered through Ca-free paper; oxalic acid and alc. are added to the filtrate; Ca oxalate is pptd. in an amorphous state and is detd. nephelometrically; the alc. hastens pptn. For clinical work, the blood is mixed with twice its vol. of 6.5% trichloroacetic acid; the mixt. is permitted to stand for 24 hrs.; and Ca is then detd. in the clear supernatant liquid. JOSEPH S. HEPBURN.

Report of the committee on uniformity in the Wassermann reaction. WILLIAM LITTEBER AND CHARLES WATTERSON. *Southern Med. J.* 11, 263-7(1918); *Abstracts*

*Bact.* 2, 180(1918).—Report of the committee of the Southern Med. Assoc. Each committee member examd. 3 sets, each of which consisted of 50 sera. With set 1, each member used his own technic and his own reagents; the results agreed in but 74% of the tests. With set 2, each member used a uniform technic and his own antigen; the results agreed in 86% of the tests. In set 3, each member used a uniform technic and a uniform antigen; practically no disagreement in results was obtained. It is concluded that a uniform technic and a uniform antigen in the hands of men trained in lab. work will give uniform results if adhered to closely in every detail. J. S. H.

**Chloride determinations in the urine of patients with kidney disease, according to Volhard-Arnold.** A. E. ALDER. *Zürich. Z. klin. Med.* 86, 80-8(1918).—Urine was obtained from patients suffering from various kidney diseases: acute hemorrhagic, chronic interstitial, chronic parenchymatous and interstitial arteriosclerotic forms of nephritis, also uro-genital tuberculosis. The values for the NaCl content of the urine were always higher in ashed urine than in urine from which the albumin had previously been removed; this was true if albumin was present in measurable amt. The pptd. albumin usually contained NaCl to an amt. which corresponded to the difference in values obtained by the 2 procedures. It is therefore recommended that, if a urine contain albumin, the urine be ashed, and the NaCl be detd. on the ash by the Volhard-Arnold method, in order to obtain an accurate result. JOSEPH S. HEPBURN.

**Adamkiewicz reaction and the transformation of glyoxylic acid to methanal.** E. VOISENET. *Bull. soc. chim.* 23, 361-9(1918); cf. *C. A.* 12, 1767.—In the A. reaction V. shows that HCHO is produced in two ways, (1) by the oxidation of the AcOH used as a reagent, (2) if any OHCCO<sub>2</sub>H is formed by oxidation of AcOH, it is in turn decompd. into HCHO and CO<sub>2</sub> by the strong acids present. The HCHO produced, rather than OHCCO<sub>2</sub>H, is responsible for the color change in the reaction. Consequently the following procedure is substituted for the glyoxylic acid reaction: To 5 drops of white of egg add 3 cc. pure 1-3 H<sub>2</sub>SO<sub>4</sub>; after soln. of the albumin, add 1 drop of com. HCHO dild. 1-100. Then 1 drop of 1% NaNO<sub>2</sub> or KNO<sub>2</sub> produces a violet color. With 1 cc. milk or a pinch of casein use 3 and 4 cc. H<sub>2</sub>O, resp., then 3 cc. of the H<sub>2</sub>SO<sub>4</sub>, bring to boiling and introduce successively a drop of the HCHO and nitrite. Concd. HCl may be used but without addition of H<sub>2</sub>O. C. H. KIDWELL.

**Studies on the submaxillary gland.** V. An automatically filling and recording spirometer. ROBERT GESELL. *Am. J. Physiol.* 47, 507-11(1919).—This is a modified Krogh spirometer. With each expiration of the animal the expiratory valve is raised so as to make an elec. connection, starting a motor which raises the float until 1000 cc. of air are admitted. The movements of the float are traced on a rotating drum, thus recording irregularities in breathing as well as the respiration vol. J. F. LYMAN.

**The relationship between the oxygen concentration and rate of reduction of methylene blue by milk.** E. HARVEY NEWTON. *J. Gen. Physiology* 1, 415-9(1919).—"The rate of reduction of methylene blue by milk and CH<sub>3</sub>CHO is proportional to the concn. of oxygen in the milk." The following method for the detn. of oxygen is given: The milk-CH<sub>3</sub>CHO-methylene blue mixture is shaken with the gas to be analyzed and the time taken for the disappearance of the blue color detd. A control mixture shaken with air is made under the same conditions. Air contains 21% oxygen and if it takes 60 min. to decolorize with air and 40 min. with the unknown gas, the calculation will be  $\frac{40}{60}$  of 21 = 14% oxygen in the unknown gas. CO<sub>2</sub> in the gas up to 5% does not affect the reducing action of milk. 2% NaF will keep milk for 2 months without affecting its reducing action. It is suggested that a protected platinum soln. might be substituted for milk in these detns. CHAS. H. RICHARDSON.

**Determination of carbon dioxide in carbonates (VAN SLYKE) 7.**

## C. BACTERIOLOGY.

**Resopon, a new antiseptic.** THEODOR ZANGGER. *Cor.-bl. f. Schweiz. Aerzte, Basel* 48, 145-6(1918); *Abstracts of Bacteriology* 2, 146.—The antiseptic action of a new compd. of S and resin is described. The compd. is not particularly bactericidal but depends for its action on its stimulation of phagocytic activity. With *Staphylococcus aureus* in a test in which 9.1% of the leucocytes showed phagocytic activity in saline soln. the percentage figures with dilns. of Resopon were: 1:120, 36.6; 1:600, 42.6; 1:6000, 25.7; 1:60,000, 17.6; and 1:600,000, 12.3. Resopon is non-toxic. The results of its use in wounds, in pyorrhea alveolaris, in diphtheretic angina, in otitis media, and in other conditions are described as favorable. E. J. C.

**Chromogenic yeasts—a new biologic reaction for iron.** M. W. BEIJERINCK. *Arch. néerland. physiol.* 2, 609-15(1918); *Physiol. Abstracts* 3, 482(1918).—*Saccharomyces pulcherrimus* secretes a colorless chromogen which becomes a deep red pigment in the presence of O and an Fe salt. On a liquid medium this yeast produces a generation free from fat; on a solid medium (agar containing malt ext. and Fe citrate) some of its progeny contain fat, others do not; the latter may eventually produce a new strain devoid of fat-producing power, *S. pulcherrimus secundarius*. Both strains produce the red pigment in the presence of Fe. Too great a concn. of this pigment is injurious; and cells with a high pigment content die. JOSEPH S. HEPBURN.

**Osmotic experiments with bacterial spores.** C. EIJKMAN. *Arch. néerland. physiol.* 2, 616-20(1918); *Physiol. Abstracts* 3, 482(1918).—Various compds. were dissolved, in increasing concns., in a slightly alk. bouillon, which was then inoculated with anthrax spores, incubated for 24 hrs., and finally examd. microscopically. The osmotic pressure of each soln. was detd. by means of the f. p. more NaCl, NaNO<sub>3</sub>, levulose, and mixts. of NaCl with asparagine or mannitol, etc., all prevented growth at practically the same osmotic pressure. Other compds., e. g., NH<sub>4</sub>Cl and urea, prevented growth by exerting a direct toxic action. JOSEPH S. HEPBURN.

**Several important edible and poisonous fungi.** R. KOBERT. *Deut. Arch. klin. Med.* 127, 47-75(1918). JULIAN H. LEWIS.

**Egg albumin as a complete food for *Isaria densa*.** MARIN MOLLIARD. *Compt. rend.* 168, 523-4(1919).—Commercial egg albumin was dissolved in H<sub>2</sub>O, coagulated by heat, filtered and washed. Enough mineral matter entered into the compn. of the protein, or was retained by adsorption, to suffice for the development of the fungus. The respiratory quotient of the fungus was detd. in the protein medium, in protein to which salts were added, and in a medium composed of protein, salts and sucrose. The values were, resp., 0.55, 0.63 and 0.82. In the protein medium large amts. of oxalic acid were formed. T. G. PHILLIPS.

**Influence of temperature and hydrogen-ion concentration upon the spore cycle of *Bacillus subtilis*.** ARAO ITANO and JAMES NEILL. *J. Gen. Physiology* 1, 421-8 (1919).—At 5°, no germination took place at  $p_H$  1-13; at 25° and 37° it occurred between  $p_H$  5 and  $p_H$  10, but not outside of these limits. The spore cycle was completed only between  $p_H$  5 and  $p_H$  10. At  $p_H$  10, the vegetative cells multiplied to a very slight extent and soon passed into spores, probably due to the unfavorable reaction of the culture medium. The automatic adjustment of the medium seemed to be an important factor in the completion of the spore cycle. Aside from the theoretical interest, the results have an important bearing on the preservation of food by canning and other methods. CHAS. H. RICHARDSON.

**Notes on the reactions of bacteriologic media.** JOHN F. NORTON. *Univ. Chicago. Am. J. Pub. Health* 9, 190-3(1919).—"Data have been presented on the relation between the titratable acidity, using phenolphthalein as an indicator, and the H-ion concn.

This relation depends entirely upon the ingredients of the medium. Sterilization effects appreciable change in the reaction of neutral and alk. media and but little change in acid media. Barnett and Chapman's titration method, slightly modified and extended, will give good results for routine lab. work. The H-ion concn. of a medium is one of the most important factors in obtaining optimum growths of bacteria. This is illustrated by the growth of pneumococci in broth of higher titratable acidity than theretofore reported, but with proper attention to the actual H-ion concn."

FRED W. TANNER.

The bacterial count in water and sewage (STEIN) 14.

#### D. BOTANY.

CARL L. ALSBERG.

Chlorophyll, carotin and xanthophyll, and the production of sugar from formaldehyde. A. J. EWART. *Proc. Roy. Soc. Victoria* 30, 178-209(1918); *Physiol. Abstracts* 3, 546.—In the assimilation of CO<sub>2</sub> chlorophyll acts as a light energizing enzyme, and takes direct part in the cycle of chem. changes, which probably have carotin, xanthophyll, phytol, and glaucophyllins as intermediate products, and glucose, levulose, formaldehyde and O as end products. A rapid method of polymerizing formaldehyde to sugar is described.

E. J. C.

New crystallizable constituent in the underground organs of *Geranium pratense* L. C. WIMMER. *Ber. deut. bot. Ges.* 35, 591-602(1917); *Physiol. Abstracts* 3, 392.—A yellow cryst. substance—probably of the nature of phenol—is described as occurring in the underground organs of various species of *Geranium*.

E. J. C.

The pigment cell of *Ricinus communis*. O. BAUMGÄRTEL. *Ber. deut. bot. Ges.* 35, 603-11(1917); *Physiol. Abstracts* 3, 392.—The red color of this plant is due to special pigment cells with homogeneous red contents. It is suggested that the red compd. is of the nature of a "tannin."

E. J. C.

The problem of nitrogen fixation by lower fungi. H. FISCHER. *Ber. deut. bot. Ges.* 35, 423-54(1917); *Abstracts of Bacteriology* 2, 269; cf. C. A. 11, 2251.—A study of the fixation of N by various bacteria, and bacteria in symbiosis with *Chlamydomonas*, from soils under water. F. holds that the fixation is due to the synthetic action of an enzyme, and that the energy of fixation of the soils in question is connected with their content of protein compds., the decompn. products of protein seeming to play a part in the production of the N-fixing enzyme.

E. J. C.

Investigation of *Chenopodium quinoa*. R. GONZÁLEZ. La Paz, Bolivia (Author), 1917, 2 ed., 45 pp.; *Expt. Sta. Rec.* 39, 610.—This publication discusses *Chenopodium quinoa* under the following topics: History, botanical characteristics, and uses; qual. and quant. chem. analyses; nutritive and digestive value; and the bitter principle of saponin. The compn. of the seed was as follows: Protein 13.125, starch 52.82, cellulose 12.2, moisture 12.5, and ash 5.44%. The compn. of the ash was silica 1.48, P<sub>2</sub>O<sub>5</sub> 1.05, 3CaO 3.01, Fe oxide 1.87, MgO 11.53, and K 38.86%. The starch was very rapidly digested by saliva. The bitter principle proved to be a saponin which has marked antipyretic properties.

E. J. C.

Recent advances in science—plant physiology. V. H. BLACKMAN. London. *Science Progress* 13, 49-53(1918).—This review discusses the factors, chiefly biochem., which govern growth and reproduction in plants, and the antagonism between these 2 phenomena.

JOSEPH S. HEPBURN.

Anatomic and biologic study of the genus *Sauranea* Willd. with special reference to American species. L. BUSCALIONI AND G. MUSCATELLO. *Malpighia* 28, 49-81,

140-62, 239-70(1917); *Physiol. Abstracts* 3, 458(1918).—The work on the degree of development of starch and tannin in the various species is of chem. interest.

JOSEPH S. HEPBURN.

**Effects of illuminating gas and its constituents in causing abscission of flowers in *Nicotiana* and *Citrus*.** T. H. GOODSPEED, J. M. MCGEE AND R. W. HODGSON. *Univ. California Publ. Botany* 5, 439-50(1918).—Presence of illuminating gas in the atm. surrounding flowering laterals of *Nicotiana tabacum* var. *macrophylla purpurea* caused the first flowers to fall in approx. one-half the normal time; the reaction time was approx. the same in all concns. of illuminating gas; the constituents of the latter, which produced premature abscission, were CO, CO<sub>2</sub>, and C<sub>2</sub>H<sub>4</sub>. These expts. were usually conducted in a moist atm. In a dry atm. containing 10% by vol. of illuminating gas, the first flower fell after approx. the same length of time in both the expt. proper and the control (without illuminating gas). In an atm. containing 5% by vol. of C<sub>2</sub>H<sub>4</sub>, the first flower fell almost as soon in the absence as in the presence of moisture, and considerably earlier than in the control without C<sub>2</sub>H<sub>4</sub>. Of the *Citrus* varieties studied, *C. sinensis* var. Washington navel showed a marked abscissional response to illuminating gas, irrespective of the concn. of the latter. *C. sinensis* var. Valencia and *C. limonia* var. Eureka showed little or no increase in the reaction time of the abscission process as a result of exposure to illuminating gas. The illuminating gas used had the following % compn. by vol.: N 4.10, O 0.10, H 55.00, CH<sub>4</sub> 26.30, C<sub>2</sub>H<sub>4</sub> 5.00, CO<sub>2</sub> 1.80, CO 7.70.

**Hydrocyanic acid in plants. III. Some new cyanogenetic plants.** J. M. PETRIE. *Proc. Linn. Soc. N. S. Wales* 42, 113-7(1917); *Expt. Sta. Rec.* 39, 332; cf. *C. A.* 9, 475.—Newly found cyanogenetic plants (*Expt. Sta. Rec.* 31, 520) as here listed include 5 native and 7 introduced species, some of which are discussed with regard to the distribution of HCN in the plant body.

E. H.

**Chemical and physical changes in apples during the ripening and storage period.** W. P. SNYDER. *Trans. Ind. Hort. Soc.* 1916, 408-11; *Expt. Sta. Rec.* 39, 121.—The apple fruit, considered as a living organism, has first a period of growth during which the dry matter, principally starch, is continually increased. A second, or ripening, period follows, during which starch is changed into sucrose. This in turn is gradually changed into invert sugar, with a gradual decrease of malic acid and of carbohydrates and in accompanying respiration of CO<sub>2</sub>. These changes are largely due to the activity of oxidizing enzymes, the O of the air being drawn upon in the process. The changes progress much more rapidly after picking, at high temps., and in the short-season varieties. Soon after picking, apples should be placed in cool storage to retard the processes above mentioned. Respiration continues during the storage period, becoming ultimately less active. Transpiration continues during the life of the apple. The third period is that of disintegration.

E. H.

**The chemical investigation of some poisonous plants in the natural order Solanaceae. IV, V.** J. M. PETRIE. *Proc. Linn. Soc. N. S. Wales* 42, 118-35, 137-45 (1917); *Expt. Sta. Rec.* 39, 433; cf. *C. A.* 12, 2345.—The first of these articles gives an account of a study of *Duboisia myoporoides* and *D. hopwoodii* (the 2 species of this genus which are best known) as regards some of their chem. components with their physiol. effects, also the total alkaloids in each plant. The results are presented in tabular form. In the second article (cf. *C. A.* 12, 1889) are presented some special studies on *D. leichhardtii*, said to be endemic in eastern Australia, though not so well known as the 2 species described above. The leaves of this species contain a mixt. of the mydriatic alkaloids, amtg. to 1.4% of the plant material dried at 100° or 0.28% of the fresh plant. *D. leichhardtii* closely resembles *D. myoporoides* as regards its alkaloids; both of these

species in this respect contrast markedly with *D. hopwoodii*, the pituri plant, which contains nicotine. E. H.

The influence of light on the absorption of organic substances from the soil by plants. DOLORES CEBRIAN DE BESTEIRO AND MICHEL-DURAND. *Compt. rend.* 168, 467-70(1919).—The object of the work was to det. whether a plant exposed to such a low light intensity that it is unable to assimilate enough C by photosynthesis to support normal growth is able to compensate for this lack by taking up org. compds. through the roots. *Pisum sativum*, a plant that grows best in strong light, was used. The plants were grown in Knop's soln. to which 4 parts per 1000 of glucose had been added. The roots grew aseptically in this culture medium. Sunlight, and light equal to  $\frac{1}{2}$ ,  $\frac{1}{3}$ , and  $\frac{1}{4}$ , the intensity of sunlight were used. In sunlight growth was more rapid than in less intense light, and more glucose was removed from the soln. The amt. of glucose removed per g. dry wt. of plant was practically const. in all the light intensities used. It is concluded that this plant is unable to make up for low photosynthetic assimilation by the absorption of org. compds. through the roots. The work is to be continued with plants that grow best under reduced illumination. T. G. PHILLIPS.

Spectrographic studies of the ash of marine plants. EUGENE CORNRC. *Compt. rend.* 168, 513-4(1919).—The complete study of the spectrograms was limited to the ultraviolet region between 2500 and 3500 Å. This serves to detect most of the heavy metals, particularly the rare metals. The following elements were found: Ag, As, Co, Cu, Mn, Ni, Pb, Zn, Bi, Sn, Ga, Mo, Au, Sb, Ge, Gl, Ti, W, V. Au, Bi, Ga, and Ge were present in the most minute traces. The species of plant used is not mentioned. T. G. PHILLIPS.

Comparative studies on respiration. VI. Increased production of carbon dioxide accompanied by decrease of acidity. MARIAN IRWIN. *J. Gen. Physiology* 1, 399-403 (1919); cf. *C. A.* 13, 241.—A high concn. of  $\text{Et}_2\text{O}$  caused an increase in oxygen consumption and in the production of  $\text{CO}_2$  in the petals of *Salvia* and at the same time caused a decrease in the acidity of the cell contents. CHAS. H. RICHARDSON.

Factors involved in the ripening of fruits. R. E. NEIDIG, C. W. COLVER, H. P. FISHBURN AND C. L. VON ENDE. *Idaho Agr. Expt. Station Report* 1917, 22-5.—A study was made of the relationships between the phys. and chem. changes involved in the ripening of different varieties of apples. The phys. consts. detd. were osmotic pressure, refractive index and elec. conductance. To follow the chem. changes, detns. were made of starch, total sugars, invert sugar, total solids and acidity. A close relationship was observed between the curves for the phys. consts. and those for sugar and total solids. The refractive index is considered a very important phys. const. for actually measuring the carbohydrate change. The elec. conductance is approx. proportional to the K content of the cell and is affected by desiccation and respiration. The carbohydrate changes which take place in the apple during growth consist of a rapid increase of invert sugar, and a rapid increase of starch which begins to diminish about Sept. 1; during ripening the decrease in starch corresponds to the rapid increase in sucrose, the content of which is low until starch begins to disappear, when it increases rapidly; after ripening and storage there is a slight increase in invert sugar followed by a continual decrease, and sucrose also gradually decreases. Analyses of green apples indicate that the hexoses are the base sugars from which the reserve material, starch and sucrose are formed. In a preliminary study on the action of sp. enzymes in the cell it was found that with one exception oxidase occurs in very green apples of all the varieties examd. Esterase was also present, but no conclusive evidence was found that indicated the presence of the enzymes diastase or invertase. W. H. R.

The chemistry of sea-weeds. JAMES HENDRICK. *Nature* 102, 494-5(1919).—While not agreeing entirely with the criticism offered by Sauvageau (*C. A.* 13, 234) on the work that has hitherto been done on the chemistry of sea-weeds, it is nevertheless admitted that much valuable work still remains to be done in this field by chemists with a competent knowledge of the botany of sea-weeds, or working in collaboration with botanists who would collect and identify the samples for analysis. W. H. R.

The water hyacinth as a source of potash (DAY) 18.

## E. NUTRITION.

PHILIP B. HAWK.

### NORMAL.

Accessory foodstuffs. H. ARON. *Berlin klin. Woch.* 55, 546-50(1918); *Physiol. Abstracts* 3, 563.—General on "vitamines." E. J. C.

Vitamines. R. KLEISSEL. *Wien. med. Woch.* 68, 601-5, 646-51(1918); *Physiol. Abstracts* 3, 563.—A general discussion of the effect of the food accessory factors on metabolism. E. J. C.

The vitamins. E. MADSEN. *Ugeskrift for Læger* 80, 613(1918); *Physiol. Abstracts* 3, 381.—Lactating women must have food rich in "vitamines." Desiccation destroys "vitamine" in fruit, vegetables, etc. M. thinks there is much to suggest that a lack of "vitamines" is a factor in chlorosis, anemia, neurasthenia, and vasomotor disturbances. War edema may be a rudimentary form of beriberi. E. J. C.

The feeding of troops. Extract from the proceedings of the permanent delegation of the sanitary commission of the allied countries, session of Nov. 8, 1917. *Arch. farm. sper.* 25, 17-56(1918).—The ration of the Italian army was changed during the war by reduction in the amount of meat and bread, and this partly compensated by addition of cheese and fresh or canned vegetables. The old garrison ration contained 146 g. protein, 31 g. fat and 517 g. carbohydrate, and supplied 3013 calories. The new ration contains 127 g. protein, 38 g. fat and 469 g. carbohydrate, and supplies 2795 calories. Bread was reduced from 750 to 600 g. per day, and meat from 1200 to 600 g. per week. The remainder of the weekly ration consists of dough 800 g., rice 410 g., beans, lentils or peas 230 g., cheese 180 g., potatoes 420 g., vegetables 750 g., and condiments. The old field ration contained 222.4 g. protein, 45 g. fat, 669 g. carbohydrate, and supplied 4082 g. cal. The new ration contains 165 g. protein, 42 g. fat, 469 g. carbohydrate, and supplies 3006 calories. The daily bread component was reduced from 750 to 700 g., and the meat from 375 to 250 g. The remainder of the weekly ration consists of dough 600 g., rice 450 g., cheese 350 g., potatoes 450 g., condiments 182 g., beans 160 g., vegetables 400 g. and wine 750 cc. Canned meat, codfish or salmon may be substituted for fresh meat. The daily allowance of coffee is 15 g. and sugar 20 g. For troops fighting in the trenches a dose of alcohol is added; with the wine distributed three times a week each soldier receives 150 cc. marsala or 40 cc. elixir of quinine. The quantity of bread may be increased 50%. The allowance of sugar and coffee, in winter or in the mountains, is frequently doubled. Finally, the potato and vegetable components are increased to 150 g. potatoes, 200 g. vegetables and 80 g. beans daily. The ration of troops in the first line is considerably increased (3200 to 3250 cal.) according to station and altitude. In the Italian navy, the ration supplies 2977 cal. for men on shore and 3036 for those on shipboard; on shore 250 g. meat, 250 g. bread; on shipboard 275 g. meat (except Friday), 570 g. bread, per day. The remainder of the ration consists of dough 640 g., rice 420 g., beans 340 g., cheese 50 g., tunny fish 50 g. on Friday, and oil 142 g. per week, besides coffee, sugar, salt and vinegar. In addition, each man is allowed daily 10 centesimi on shore and 12 centesimi on shipboard for the purchase

of vegetables. To men on board 250 cc. wine per day is issued, and to those on shore 250 cc. per week. Fishing is encouraged during leisure hours to supplement the ration.

**Use of vegetable milk in children.** HENRY D. CHAPIN. *Arch. Pediatrics* 36, 28-31(1919); cf. *C. A.* 12, 1793.—A description of the prepn., compn., properties, and use of almond milk.

JOSEPH S. HEPBURN.

**Report of the Cornell nutrition class.** MAY G. WILSON. Cornell Univ. Med. College. *Arch. Pediatrics* 36, 37-44(1919).—Of interest to the student of nutrition.

JOSEPH S. HEPBURN.

**Study of the metabolism of the Japanese laboring classes.** B. KOMU AND T. SOKAMOTO. *Jusenkaï Zasshi* 22, No. 10, 50-2(1917); *Jap. Med. Literature* 4, 7-8 (1919).—Two laborers of av. strength worked for from 13 to 14 hours daily. The av. daily food consumption by one laborer was 3786 cal. of which protein supplied 333 cal., fat 169 cal., carbohydrate 3148 cal. and alc. 136 cal.; by the other laborer 3746 cal., of which protein supplied 375 cal., fat 182 cal., carbohydrate 3125 cal., and alc. 64 cal. A laborer was unable to work on a diet of salted radish and rice; the intake of N was 9.77 g., the output 12.3 g.; addition of hashed fish to the ration rapidly restored the N equil., and made possible resumption of work.

JOSEPH S. HEPBURN.

**Influence of light on the formation of creatinine.** C. J. C. HOOGENHUIJZE AND J. W. BEST. *Arch. néerland. physiol.* 2, 685-8(1918); *Physiol. Abstracts* 3, 452(1918).—The influence of light on endogenous metabolism was studied by detn. of the creatine and creatinine content of the urine. A creatine- and creatinine-free diet was taken for 2 days, and the amt. of these compds. present in the urine was then detd. for 3 days in order to obtain a normal av. The following day 1 of the investigators sat for 20 min. in a box lined with incandescent lamps, and having a temp. of 40 to 45° when closed and 35 to 36° when ventilated. In a series of 4 expts., exposure to light and heat or to light alone always produced a considerable increase in the creatinine; creatine was always absent; a negligible effect was produced by exposure to heat alone. A similar increase in creatinine occurred in 2 patients after a sun bath, and in several other patients after partial exposure of the body to X-rays.

JOSEPH S. HEPBURN.

**Researches on uric acid metabolism in man.** F. GUDZENT, C. MAASE AND H. ZONDEK. *Z. klin. Med.* 86, 34-63(1918).—Uric acid should be detd. in both blood and urine, in studies of purine metabolism. Administration of nucleic acid to healthy persons and to leukemia patients produced a parallelism between the uric acid of the blood and of the urine. Exts. of glandular organs (thyroid, pancreas, spleen, adrenals) produced a somewhat transient, but considerable, increase in the uric acid content of both the blood and the urine. The gout remedies—colchicum, atophan, and thorium X (used as a radio-active substance)—gave rise to a temporary increase in the uric acid content of both fluids; purgatives produced a similar result. Astringents exerted no action on the purine metabolism. Ca, and possibly I, increased the uric acid content of the urine and decreased that of the blood, evidently by action on the kidney.

JOSEPH S. HEPBURN.

**Question of the digestibility of heated and unheated casein.** O. HAMMARSTEN. *Arch. néerland. physiol.* 2, 658-63(1918); *Physiol. Abstracts* 3, 441-2(1918).—A 3 to 4% soln. of tetra- or penta-alkali caseinate was prepd. and a portion of the soln. was heated in an autoclave for 1 hr. at a temp. of 115 to 125°. The casein was then converted into acid caseinate and digested with com. rennet for 17 min. at 38° in the absence of free HCl; the denatured (heated) casein yielded more proteose than did the unheated casein. Heated caseinate solns. contained a certain amt. of proteose and a readily

digested casein-like substance, which was pptd. by acid; in 1 expt. 70% of this mother substance was digested to proteose by rennet in less than 10 min. at body temp.

JOSEPH S. HEPBURN.

**Diet, nutrition, and excretion of Asiatic races in Singapore.** II. J. A. CAMPBELL. *J. Straits Branch R. A. Soc.* 79, 107-12(1918); *Physiol. Abstracts* 3, 565; cf. *J. Straits Branch R. A. Soc.* 76, 57-65(1917).—The present paper relates to laborers (Chinese bakers, jinriksha runners, rubber coolies, Tamil gardeners, etc.). The observations are not very numerous, but the figures show that the urine differs materially from that in European laborers. The total N varied from 7.2 to 11.4 g. *per diem*; details of its partition are given, and the high proportion of  $\text{NH}_3$  is specially noted; uric acid, Cl, and  $\text{P}_2\text{O}_5$  are low. The diet so far as fat and protein are concerned is low. The total calories are small. The hot moist climate is a factor; so also is the small amt. of work the laborers perform. As McCay has already pointed out, their general physique is inferior to that of Europeans.

E. H.

**Bakers' yeast as food for man.** P. B. HAWK, C. A. SMITH AND R. D. HOLDER. *Am. J. Physiol.* 48, 199-210(1919).—Bakers' yeast can replace from 9 to 29% of the protein in the diet of man without detriment to the best nutritive interests of the individual. Utilization of the food, retention of protein, maintenance of body wt. and general conditions of health are regarded as favorable to the yeast food. When as much as 4 g. yeast N is consumed per day a laxative effect is usually noticed.

J. F. LYMAN.

**Compressed yeast as food for the growing organism.** P. B. HAWK, H. R. FISHBACK AND OLAF BERGEM. *Am. J. Physiol.* 48, 211-20(1919).—Diets consisting of casein 20%, starch 63%, butter fat 15% and salt mixture 2%, or of dried meat 20%, starch 63%, butter fat 15% and salt mixture 2% will not support growth in young, white rats. The addition of 5% dry yeast to the above diets, deficient in water-soluble vitamin, gives rapid growth in both cases. Heating the yeast to 105° did not destroy its growth-promoting properties.

J. F. LYMAN.

**Influence of the principal constituents of sweetened condensed milk on the nutritive and therapeutic effects of the latter.** P. LASSABLIÈRE. *Compt. rend. soc. biol.* 81, 764-7(1918).—Sweetened condensed milk (a), unsweetened condensed milk (b) and unsweetened condensed milk with 10% of added sucrose (c) were fed (650 cal. per 24 hrs. ration in all cases) for 1 mo. to 5 mos. old infants; the increase in wt. observed was in the increasing order (b), (c), (a). Addition of sucrose to (c) had a favorable influence on increase in wt. but did not render (c) equal in value to (a) in this respect. In order to det. the influence of varying concns. of sucrose 4, 5 and 8 mos. old infants were given a diet of sweetened condensed milk dild. with  $\text{H}_2\text{O}$  so as to contain 6, 8 and 10% of sucrose, milk of each concn. being fed to infants of each of the ages above mentioned; the caloric values of the 24-hr. rations were 600, 650 and 750 cal. for 4, 5 and 8 mos. old infants, resp. The greatest increase in wt. was observed with the normal dild. corresponding to 8% of sucrose; less favorable results were obtained with the 10% than with the 6% concn. This result explains to a certain extent the various opinions which have been held with respect to the use of sweetened condensed milk. Study of the influence of sweetened condensed milk, sterilized milk and milk powder in gastro-intestinal disorders showed that the 1st named was distinctly superior to the others in its therapeutic effect; this was detd. by noting the no. of days of each diet which were required to arrest diarrhea and vomiting. A similar comparative study of the influence in gastro-intestinal disorders of (1) sweetened condensed milk dild. to 10% sucrose content, (2) unsweetened condensed milk and (3) unsweetened condensed milk with 10% added sucrose (rations of same caloric value in each case) showed that the favor-

able effect produced was in the increasing order (2), (3), (1). Sucrose has, therefore, a positive and favorable effect but this is not sufficient to explain the order of results obtained with sweetened condensed milk.

#### ABNORMAL.

**Experimental mammalian polyneuritis produced by a deficient diet.** C. VOEGTLIN AND G. C. LAKE. *Am. J. Physiol.* 47, 558-89(1919).—See C. A. 12, 2355.

J. F. LYMAN.

The deficiency theory of the origin of beri-beri in the light of clinical and experimental observations on the disease, with an account of a series of forty cases. F. M. R. WALSH. *Quart. J. Med.* 11, 320-38(1918).—A consideration of the deficiency theory of the origin of beri-beri in the light of recent clin. and exptl. work makes it clear that the present hypothesis, which postulates a single neg. factor, the absence of a sp. accessory food factor or vitamine, is inadequate. It conflicts with the results obtained in starvation expts. on fowls. Starved fowls live sufficiently long to develop the disease under such conditions, yet they die without developing it, although in this essential respect, namely, the deprivation of vitamins, starvation is the equiv. of an avitaminic diet. The use of certain special diet is found to be an essential condition of the production of the disease both in man and poultry. It is apparent that there are two factors in the production of beri-beri, the absence of an accessory food factor or vitamine and the use of certain foods which are the direct and immediate cause of the disease. There is a considerable wt. of evidence to prove that carbohydrates constitute this second direct and immediate factor. It seems probable that in the absence of their sp. vitamine they undergo an aberrant hydrolysis with the production of toxic by- and end-products, thus producing beri-beri. Viewed in this light the disease is an intoxication. The facts regarded as excluding a toxic origin of beri-beri do not exclude an intoxication in this sense. From another point of view, it may be questioned whether the clin. and pathol. characters of the disease are compatible with the theory that it is a slowly progressive diffuse degeneration of the nervous system. A consideration of the phys. and chem. properties of vitamins, as far as they are known, suggests the probability of their belonging to the class of bodies known as enzymes, and of their being thus concerned in the hydrolysis of carbohydrates. It seems certain that until the phys. chemistry of the vitamins and the metabolism in beri-beri have been more fully investigated, the pathogenesis of beri-beri will remain in part obscure. The article has a bibliography of 26 titles.

JOHN T. MYERS.

**Excretion of xantho-uric compounds from the standpoint of the pathogeny of gout.** J. CHAUSSIN. *Compt. rend. soc. biol.* 81, 234-7(1918).—C. studied the variations in concn. of uric acid and xanthic compds. (detd. *en bloc* by the Haycraft-Denigès method and designated as "xantho-uric" compds.) in the urine of a no. of subjects during the course of a 24 hr. period (8-10 successive samples in 24 hrs.). Three characteristic types of excretion were encountered. In the 1st type (regarded as normal) chlorides and urea were excreted at concns. varying 4-fold or more; the max. concns. were 23 g. and 52 g. per l. for chlorides and urea, resp. The xantho-uric compds. were excreted at concns. varying from 0.59 g. to 1.68 g. per l. In the 2nd type the concns. of chlorides and urea did not vary greatly during successive intervals and attained maxima of only 13 g. per l. for chlorides and 20 g. per l. for urea. The concn. of xantho-uric compds. varied from 0.65 to 1.50 g. per l. This type shows that normal xantho-uric excretion may be associated with diminished chloride and urea elimination. In the 3rd type (gout) the xantho-uric concn. was remarkably uniform and only varied from 0.33 g. to 0.48 g. per l.; 0.50 g. per l. may be regarded as the max. limit. Urea and chlorides were not detd., although with an ordinary diet they appear to be eliminated in practically normal amt. with considerable differences in concn. at successive intervals. H. S. PAINE.

**Relative to appearance of antiscorbutic substances during germination of cereals.** E. WEILL, G. MOURIQUAND AND Mlle. PÉRONNET. *Compt. rend. soc. biol.* 81, 678-9 (1918).—Replying to comments by Netter relative to their investigation of this subject (cf. *C. A.* 13, 749) the authors state that the precautions emphasized by Chick and Hume were observed and claim that the results obtained cannot be attributed to simple inanition. H. S. PAINE.

**Significance of "carence" in the interpretation of the results of investigations of artificial alimentation and aseptic life.** E. WEILL AND G. MOURIQUAND. *Compt. rend. soc. biol.* 81, 1253-4 (1918).—The significance of "carence" has been overlooked to a great extent in investigations on artificial alimentation of the higher animals and the interpretation of these results has been subject to error. The results of Forster's expts. (feeding of demineralized meat to dogs in order to prove the necessity for inorganic constituents in the diet) are due in considerable measure at least to the absence of vitamines. The same objection may be made to the expts. of Lunin, Sonin, Knapp, Jacob, Rohmann, Falta and Noeggerath. Absence of vitamines also doubtless played a considerable role in the results obtained by Nuttal and Thierfelder, Charrin and Guillemonat, Schottelius, Kuster and Cohendy in expts. in which sterilized rations were fed to chickens, guinea pigs and kids. The results obtained led some of these investigators to believe that life cannot be sustained in the absence of bacteria. In order properly to det. this question the rations should be aseptic but not sterilized by heating or at least it is necessary that the ration should contain a certain proportion of "fresh," aseptic food. Although vitamines are not so indispensable to lower organisms it is probable that the more favorable results sometimes obtained with bacterial cultures in media which have not been sterilized by heating are due to the presence of vitamines; this idea is in accord with the improved results obtained by Noguchi with spirochete cultures when a fragment of fresh kidney was introduced into the medium. The role of vitamines should never be disregarded in studies on nutrition. H. S. PAINE.

#### F. PHYSIOLOGY.

ANDREW HUNTER.

**Amylolytic action of urine.** W. R. FEARON. *Dublin J. Med. Sci.* No. 562, 149-83 (1918); *Physiol. Abstracts* 3, 569.—The methods adopted were to det. the achromic point and the amt. of reducing substances formed, in preference to Wohlgemuth's. The amylase present was not identified; its amt. varies in health, and is reduced in nephritis and to a less extent in diabetes. E. J. C.

**The composition of the blood of aviators.** A. GEMELLI. *Arch. ital. biol.* 1917, published 1918, 67, 197-205; *Physiol. Abstracts* 3, 512.—The view is advanced that cold is the main cause of the increase of red corpuscles found in the blood of airmen. E. J. C.

**Physiological action of urea.** S. BAGLIONI. *Arch. ital. biol.* 67, 49-68 (1917); *Physiol. Abstracts* 3, 500.—The old observation that the blood and tissues of selachian fishes are rich in urea is confirmed, and the view is advanced that in these animals it plays a useful role. It is regarded as necessary for the maintenance of heart rhythm as NaCl. In perfusion expts. it elevates the cardiac tonus, and therefore opposes NaCl. Perhaps it is essential for the maintenance of function in other organs also. The kidneys of these fishes only remove from the blood a small percentage of its urea, the blood remaining relatively rich in that substance. Details are added of the compn. of the body fluids and urine of various worms, molluscs, and arthropods, and among the statements is one that the normal urine of the octopus contains albumin. E. J. C.

**Contribution to the study of human enamel, with special reference to its nutrition.** JOHN S. MARSHALL. *Univ. Calif. Dental Items of Interest* 41, 216-29 (1919).—Sec-

tions—usually 10 to 12 micra thick—were prepd. from fresh teeth by grinding. Staining was best done in vacuum prior to grinding. Blue dyes (gentian violet, aniline blue, methylene blue) were most satisfactory; next came  $\text{AgNO}_3$ ; red dyes (eosin, safranin) were far from satisfactory. By this technic, the enamel was shown to contain very numerous cul-de-sacs, which are connected with the dentinal tubuli, and possibly supply nutrition to the enamel.

JOSEPH S. HEPPBURN.

**Contributions to the physiology of the glands. I. ASHER. XXXV.** The dependence of the inner secretion of the pancreas on the nervous system. J. M. DE CORRAL. *Z. Biol.* 68, 395-418(1918); *Physiol. Abstracts* 3, 456(1918).—The exptl. animals were 8 dogs, which were kept under anesthesia by ether plus morphine or urethan; the nerve supply of the liver was destroyed with pure  $\text{PhOH}$  in the periportal region; the influence on the pancreatic hormone of vagus stimulation, produced by induction shocks (1 min. stimulation and 1 min. rest alternately for 10 or more min.) was then detd. Vagus stimulation decreased the blood sugar (quant. detn. by Bang's micro-method) whether the content prior to stimulation was normal or abnormally high as a result of hyperglycemia of anesthesia. The rapidity of this change indicated an increase in sugar cleavage as the main action of the pancreatic hormone. Introduction of a resting period sometimes produced an increase in blood sugar. The same procedure minus vagus stimulation caused an increase in blood sugar. The results indicate the existence of stimulating fibers in the vagus for the internal secretion of the pancreas.

JOSEPH S. HEPPBURN.

**"Staircase" in the curve of muscular work. I. GUNZBERG. Arch. néerland. physiol.** 2, 664-8(1918); *Physiol. Abstracts* 3, 415(1918).—In a study of this phenomenon, the gastrocnemius of the frog was perfused with Ringer soln. minus K for 6 to 24 hrs., and the sciatic nerve was stimulated by induction shocks every 2 sec. When a continuous current of O was bubbled through the perfusing liquid, a very prolonged staircase effect was produced, probably as the result of metabolic processes necessary for production of a sufficient concn. of lactic acid, formation of which is retarded by O. These results were proved and verified by the action of  $\text{CO}_2$  which produced a more rapid ascent of the staircase.

JOSEPH S. HEPPBURN.

**Hydrolysis of whale muscle protein. Y. OKUDA AND T. OKIMOTO. Tokyo Kwagaku Kwai Shi. (J. Tokyo Chem. Soc.)** 40, 60-7(1919).—Whale muscle was extd. with  $\text{H}_2\text{O}$ , alc. and  $\text{Et}_2\text{O}$ , from which protein was isolated as usual. The material for the hydrolysis thus obtained contains 4.23%  $\text{H}_2\text{O}$ , 15.96% N and 0.29% ash. The distribution of N in the dry ash-free substance is as follows: 15.99% N sol. in  $\text{H}_2\text{SO}_4$  (0.51% humin N, 0.51% amino N, 5.18% basic org. N; 9.39% mono-amino acid N), 0.72% N insol. in  $\text{H}_2\text{SO}_4$ . Hydrolyzing the protein, 4.66% alanine, 6.25% valine, 3.54% leucine, 1.51% probine, 2.59% phenylalanine, 1.47% aspartic acid, 3.28% glutamic acid, 0.49% serine, 2.40% tyrosine, 6.48% arginine, 3.44% histidine, 9.48% lysine, 0.91%  $\text{NH}_3$  + tryptophan were isolated.

S. KOMATSU.

**Hydrolysis of cod muscle protein. Y. OKUDA AND T. YADA. Tokyo Kwagaku Kwai Shi (J. Tokyo Chem. Soc.)** 40, 67-75(1919).—The protein for hydrolysis was prepd. from cod muscle by the usual method. It contained 13.74%  $\text{H}_2\text{O}$ , 14.80% N and 0.61% ash. The dry ash-free protein contained 17.02% N sol. in  $\text{H}_2\text{SO}_4$  and 0.25% N insol. in  $\text{H}_2\text{SO}_4$ . On hydrolysis, O. and Y. obtained the following results: 3.53% alanine, 3.88% valine, 2.46% leucine, 1.68% probine, 2.31% phenylalanine, 0.61% aspartic acid, 5.24% glutamic acid, 0.51% serine, 2.46% tyrosine, 6.68% arginine, 2.29% histidine, 8.35% lysine, 0.75%  $\text{NH}_3$  and tryptophan.

S. KOMATSU.

**Effect of osmotic pressure on the excitability of the nerve. R. SHOJI. Am. J. Physiol.** 47, 512-33(1919).—When nerves are immersed in solns. of varying osmotic

pressures their elec. resistance is so changed that excitability cannot be estimated by measuring the threshold strength of elec. stimulus. Rather excitability should be detd. by the propagation velocity of excitation through the affected part of the nerve. The optimum osmotic pressure for excitability of the nerve is  $\Delta = -0.4^\circ$ , which is that of a 0.7% NaCl soln. A higher or a lower osmotic pressure than this decreases the excitability of the nerve.

J. F. LYMAN.

The stimulation and inhibition of the gastric secretion which follows the subcutaneous administration of certain organ extracts. JOHN ROGERS, JESSIE M. RAHE AND ELEEZA ABLAHADIAN. *Am. J. Physiol.* 48, 79-92(1919).—Subcutaneous injection of various glandular exts. affected gastric secretion in dogs having Janeway fistulas through which the gastric juice could be withdrawn by catheter. Alk. saline exts. or alc. exts. of thyroid glands contain non-coagulable substances which are vigorous stimulants for gastric secretion, acting probably on the terminal filaments of the vagus. Exts. from adenomatous or hyperthyroid human glands are inert. Exts. of the adrenal glands vigorously inhibit gastric secretion, the adrenal nucleoproteins being more active than the non-coagulable portion. Pituitary exts. inhibit gastric secretion but only about one-half as vigorously as do exts. of adrenals.

J. F. LYMAN.

The mechanism of ether hyperglucemia. R. W. KEETON AND E. L. ROSS. *Am. J. Physiol.* 48, 146-60(1919).—Hyperglucemia, induced in dogs by ether anesthesia, is persistent but if the splanchnic nerves are severed it is only transient. When the liver is denervated but the nerves to the adrenals left intact ether anesthesia causes persistent hyperglucemia of a lower grade than in the normal animal. The mechanism of glucemia by ether and that by elec. stimulation of the splanchnic nerve are believed to be identical.

J. F. LYMAN.

The influence of internal secretions on the formation of bile. A. W. DOWNS AND N. B. EDDY. *Am. J. Physiol.* 48, 192-8(1919).—The amt. of bile secreted is (1) increased by secretin, (2) decreased by adrenaline, and by mammary, testicular ovarian, pancreatic and thymus glands, (3) not affected in a definite way by spleen and thyroid.

J. F. LYMAN.

Alterations in the activity of the terrapin's heart relative to slight changes in the  $P_H$  value of the perfusate. E. C. ANDRUS. *Am. J. Physiol.* 48, 221-30(1919).—Normal terrapin blood has a  $P_H$  value of 7.4 to 7.5. Variations of acidity in the Ringer soln. perfusing the isolated heart, within physiol. limits, markedly affect the tonus and amplitude of the heart muscle. A decrease in acidity to a  $P_H$  value of 7.6 to 7.8 causes a rapid increase in tonus, especially in the auricles, and a decreased amplitude. A rise of the  $P_H$  value to 7.3 increases the cardiac output in either or both of 2 ways, i. e., by a decrease in tone and hence an increase in initial vol. or by an increase in the amplitude of beat.

J. F. LYMAN.

The respiration and oxyhemoglobin dissociation curves and buffer value of the blood in normal men. L. S. DEBENHAM AND E. P. POULTON. *Quart. J. Med.* 12, 38-60(1919).—The object of this paper is to consider what exptl. methods are suitable for investigating the respiration in pathol. conditions, and to bring forward certain measurements on normal men to serve as a standard with which to compare similar measurements in pathol. conditions. The pulmonary ventilation, alveolar  $CO_2$ , alveolar ventilation, tidal air, dead space, and respiratory exchange have been measured in ten normal men at rest in bed. The methods described by Haldane and Priestley, and by Hasselbalch and Lindhard, for measuring the alveolar  $CO_2$  were compared, and show satisfactory agreement. Values for K (the const. of the oxyhemoglobin dissociation curve at the alveolar  $CO_2$  pressure, were detd. in eleven normal men, and agree with values previously published. It is not by any means certain that the blood has a lower

buffer value in cases of irritable heart. The buffer value of the blood was studied in three cases of acidosis and as measured by the  $\text{CO}_2$  was much the same in the three cases. Twenty-four references are appended.

JOHN T. MYERS.

**Relation between thyroid gland, metamorphosis, and growth.** EDWARD UHLENHUTH. *J. Gen. Physiology* 1, 473-82(1919).—Two substances are involved in the metamorphosis of the amphibian, *Ambystoma opacum*, namely iodine taken up by the food and an excretor substance evolved during growth which induces the excretory function of the thyroid gland. Larvae in which the metamorphosis is inhibited by the lack of iodine have their growth checked because the excretor substance brings about the excretion of toxic substances from the thyroid gland. These toxic substances break down the proteins and thus decrease the size of the larvae. When the thyroid gland is removed or in species which have an hereditary lack of it, the animal grows normally, since the thyroid is not present to excrete the toxic growth-inhibiting substances. At low temp. less excretor substance is produced and consequently larvae kept at a low temp. reach a larger size than those kept at a high temp. (cf. C. A. 13, 864, 878).

CHAS. H. RICHARDSON.

### G. PATHOLOGY.

H. GIDEON WELLS AND ANDREW HUNTER.

**Enzyme studies in carcinoma.** B. BRAEN. *Z. Krebsforsch.* 16, 112(1917); *Abstracts of Bacteriology* 2, 154.—A study of the catalase, lipase, and lecithinase content of the autolyzed livers of healthy and carcinomatous individuals. Autolyzed carcinoma and sarcoma have a very low enzyme content in comparison with normal liver.

E. J. C.

**The chemico-biological processes in cancer.** F. BLUMENTHAL. *Z. Krebsforsch.* 16, 58(1917); *Abstracts of Bacteriology* 2, 154.—A review of the results of enzyme investigations on malignant tumors.

E. J. C.

**An application of Vernes' method. Influence of the aging of the serum on the sero-diagnosis of syphilis.** ROGER DOURIS. Nancy. *Bull. sci. pharmacol.* 26, 49-53(1919).—Using the method of Vernes, D. found that normal serum collected aseptically and kept on ice, when tested from week to week, showed a regular transition in characteristics to that of syphilitic serum, *e. g.*, lowered hemolytic power. Serum from syphilitics loses what hemolytic power it has more quickly than does normal serum. The reaction is more rapid when samples are kept at ordinary temp. NaF 1-2 mg. per cc. retards the reaction. *Treponema pallidum* produces in the serum of syphilitics modifications analogous to those which time produces in normal serum. The age of the serum is therefore a factor concerning which account must be taken among the conditions regulating the sero-diagnosis of syphilis. Cf. C. A. 12, 915, 2009; 13, 459.

F. S. HAMMETT.

**Coagglutination in growing cultures.** G. CAPONE. Mogliano Veneto. *Sperimentale* 72, 429-40(1918).—By means of cross agglutination expts. with anti-typhoid, anti-paratyphoid A and B, and anticholera sera of high titer it is shown that homologous species are agglutinated to the same extent either in growing broth culture or in saline suspension. Heterologous species, however, show agglutination in higher dilns. by the former method, especially in the early hours of growth, when the no. of bacteria is not out of proportion to the relatively small amt. of secondary agglutinin present and the agglutination produced is not masked by a heavy growth. This is apt to occur in older cultures and is responsible for the lower values of the coagglutination obtained in saline suspensions. An expt. showed that after the secondary agglutinins for 2 heterologous species had been absorbed the serum retained its original titer for the homologous organism. Details and tables are given.

M. HEIDELBERGER.

**Mixed infections.** A. ZIRONI AND G. CAPONE. Moghiano Veneto. *Sperimentale* 72, 441-52(1918).—By means of bacterial aggressins derived either from cultures themselves, or from pathological exudates, it is possible to render pathogenic microbes which are innocuous by themselves. When rendered pathogenic these microbes invade the organism with the rapidity of the most pathogenic bacteria known, causing varied lesions. An anaerobe, made pathogenic in this way, produced lesions like those of malignant edema. M. HEIDELBERGER.

**Thrombosis due to blood platelets in the treatment of vascular wounds.** SILVANO MENGHETTI. Univ. Perugia. *Sperimentale* 72, 453-8(1918).—Thrombosis due to the blood platelets, and resulting usually in quick hemostasis, may be induced by the transplantation (*trapianti liberi*) of adipose tissue on to the lesion of the blood vessel (cf. *Sperimentale* 68, Nos. 1 and 4), suturing being unnecessary. M. HEIDELBERGER.

**Supposed transformation of anaerobic bacilli in gas gangrene.** G. M. FASIANI. Moghiano Veneto. *Sperimentale* 72, 459-81(1918).—In a large no. of expts. which are given and tabulated in detail it was found impossible to induce or observe any essential alteration in the characteristics of the many strains and species of gas bacilli started with. Differences in the bacteriological findings in different parts of the invaded tissues or at different times in the same tissue are not due to transformation of the bacteria but to the overgrowth of one type or another due to changing cultural conditions in the infected area. The results are in direct contradiction to those of Conradi and Bieling (*Münch. med. Wochschr.* 1916, No. 44). M. HEIDELBERGER.

**Basophilic granulocytes in leucemic blood.** N. TIBERTI. Univ. Sassari. *Sperimentale* 72, 482-96(1918).—The staining of these cells is very difficult, the best methods being that of May-Grünwald, and those involving the use of "*Dahlia acetica*" or an alc. soln. of thionin. Treatment with acetone shows the basophilic granulocytes to be composed of a lipoid fraction and an albuminoid portion. The origin of the cells is discussed. M. HEIDELBERGER.

**Etiology of dental caries.** RAGNAR ECKERMANN. Malmo, Sweden. *Dental Items of Interest* 41, 85-9(1919).—Polemic reply to Bunting's critique (*C. A.* 12, 2213). JOSEPH S. HEPBURN.

**Studies of snake venoms. III. Action of snake venoms on proteins.** B. A. HOUSSAY AND J. NEGRETE. *Rev. inst. bact. Buenos Aires* 1, 341(1918); *Physiol. Abstracts* 3, 462-3(1918).—Many of the conclusions are contained in a paper already abstracted (*C. A.* 12, 2372). The venoms of *Lachesis*, *Ancistrodon*, and *Crotalus adamanteus* possess marked proteolytic power; those of *Naja tripudians*, *Elaps marocrovi*, *Crotalus terrificus*, *Pseudechis porphyracus*, *Notechis scutatus*, and *Vipera Russellii* have this power to a slight degree. The proteolytic substances are thermolabile, and are specifically neutralized by anti-venom sera. JOSEPH S. HEPBURN.

**Specific precipitins in antiphidic sera.** B. A. HOUSSAY AND J. NEGRETE. *Rev. inst. bact. Buenos Aires* 1, 15-31(1917); *Abstracts Bact.* 2, 114-5(1918).—Horses were immunized to the venoms of *Crotalus terrificus*, *Lachesis alternatus* and *L. Newwiedi*, and their sera tested for antitoxin and precipitin. A highly potent antitoxic serum generally, but not always, possessed a high precipitin titer, which was detd. by addition of varying amts. of venom to a constant amt. of antiphidic serum. All the sera tested pptd. venoms of *Lachesis alternatus*, *L. jararacussu*, *L. Newwiedi* and *L. lanceolatus*. Characteristic pptn. curves were obtained; clouding was most marked in the tubes containing the most venom, became less marked in the following tubes, and then increased in those containing the least serum; this phenomenon was more marked in homologous than in heterologous systems. Pptn. was relatively specific; when non-specific, it was most marked if the species furnishing the immunizing venom and the pptg. venom were

closely allied; thus a serum against *L. alternatus* venom gave reactions with other venoms: very intense with *L. lanceolatus*, strong with *L. Neuwiedi* and with *L. ammodytoides*, slight with *L. atrox*, very slight with *L. jararacusú* and with *Crotalus terrificus*, no reaction with *L. flavoviridis* and with *Naja tripudians*. The optimum amt. of serum for the pptn. test closely approximated that required to neutralize the toxin (venom) used. The ppts. were more intense than those obtained with cobra venom and its antiserum, and differed from the latter ppts. in not being dissociated by heating at 72°. Venom of *L. alternatus* lost its pptg. and toxic properties on heating at 65° for 30 min. "Antiphidic sera do not yield a reaction with the blood sera of other species, nor will antiphidic sera neutralize the toxicity of the venom of other snakes. However, those sera which ppt. the snake serum will form ppts. with the venoms." J. S. H.

**Histology, histo-chemistry and pathogenesis of Dercum's lipomata.** C. MARTELLI. *Tumori* (Rome) 6, 1(1918); *Endocrinology* 2, 319-20(1918).—The histologic structure and characteristics of this type of tumor are described. The lipomatous cells chiefly contain neutral fat, mixed, in 2 to 3% of the cells, with fatty acids. Common lipins occur in greater amt.; lecithin, cholesterol, and chromolipins are present in very scant amt., if at all; Ca is absent. Such lipomata are ascribed to disturbed equil. of lipogenesis due to multiple endocrine-sympathetic disfunction, chiefly suprarenal. Adrenaline therapy produces good effects. JOSEPH S. HEPBURN.

**Preliminary report on the virulence of certain body organs in rinderpest.** WILLIAM H. BOYNTON. *Philippine J. Sci.* 13B, 127-50(1918).—The virus of rinderpest held in certain tissues of the body of diseased animals is not injured when extd. by dil. solns. of PhOH. The virus is quickly destroyed in decomposing material (tissue or blood), but retains its activity for 5 or 6 days if virulent blood be drawn under aseptic conditions and placed in sterile containers, and retains its activity for a few days longer if the blood be kept in clotted form. By extn. of certain organs with dil. PhOH soln., the activity of the putrefactive organisms is reduced to a minimum, and they exert little or no effect on the virus. For ordinary immunization work it is best not to use an ext. over 15 days old. "We have obtained a considerable number of very gratifying results with old exts. .... the animals presented no reaction to the injection. After a period of 2 weeks these animals were exposed to rinderpest by various methods, that is, by exposure to sick animals, inoculation with virulent blood, and inoculation with exts. These animals presented no ill effects from the exposures to which they were subjected, showing that they had been immunized by the primary injection of ext." Aq. exts. of liver, spleen, and lymph glands 3 days old were highly infectious to susceptible animals. Five-day-old exts. of (1) liver, spleen and lymph glands, (2) cardiac muscle, and (3) cecum and colon in 0.5% PhOH were highly infectious to susceptible animals. The ext. of liver, spleen, and lymph glands in this concn. of PhOH retained the virus in virulent form for periods varying from 8 to 35 days. When 1% PhOH was used for extn., the following results were obtained with susceptible animals: exts. of lymph glands 6, 17 and 20 days old, resp., and ext. of liver, spleen, cecum, and lymph glands 17 days old were highly infectious; ext. of liver and ext. of spleen, both 21 days old, were virulent. An ext. of spleen in 2% PhOH 5 days old was infectious to susceptible animals. The virus had become destroyed in an ext. of lymph glands in 2% PhOH, 8 days old. When spleen was extd. for 3 days with a mixt. of 1 vol. glycerol and 3 vols. H<sub>2</sub>O plus 2% PhOH, the virus was destroyed. The organs best adapted for the prepn. of exts. were: liver, spleen, lymph glands, heart, fourth stomach, cecum, and colon; skeletal muscle, larynx, pharynx, base of tongue and pancreas were not suitable for this purpose. It was advisable to use a 0.75% PhOH ext. not over 15 days old. It is suggested that similar results may be obtained with the virus of hog cholera. JOSEPH S. HEPBURN.

**Antigen for the miostagmin reaction in malignant tumors.** A. H. ROFFO. *Rev. inst. bact. Buenos Aires* 1, 53-7(1917); *Abstracts Bact.* 2, 85(1918).—A transplantable tumor of the albino rat, of 15 to 20 days' growth and free from degenerative zones, was triturated to a paste, spread on plates, dried *in vacuo*, and pulverized; 1 part of powder was digested with 30 parts of 96% alc., for 24 hrs. at 37°; the alc. soln. was then decanted; and the residue was digested with 150 cc. alc. for 24 hrs. at 37°. This alc. ext. was removed and combined with the first alc. ext.; the residue was digested with Et<sub>2</sub>O in a tightly stoppered flask for 24 hrs. at 37°. The ether ext. was added to the combined alc. exts., which were then evapd. slowly, obtaining a dark pasty mass; the latter was dissolved in a mixt. of xylene and acetone (1:5), and filtered. This new antigen was more satisfactory than that prepd. from egg lecithin, for it had a higher drop number, was more stable (the titer remained const. for several months), and was more readily prepd.

JOSEPH S. HEPBURN.

**Serum therapy in scarlet fever.** C. KLING AND G. WIDFELT. *Hygiea (Stockholm)* 1, 1-37(1918); *Abstracts Bact.* 2, 322(1918).—During the epidemic of scarlet fever in Stockholm (1916-17) serum treatment was very successful. Serum was prepd. from convalescents with healthy blood, and was of equal value whether the patient had suffered from the light, medium or severe form of scarlet fever. The blood was usually drawn during the 5th or 6th week after the first appearance of the disease, but also yielded an effective serum if drawn during the 4th or 7th week. Secondary ill results from use of the serum were never noted.

JOSEPH S. HEPBURN.

**Complement fixation test for tuberculosis in infancy and childhood.** HENRY HERMAN. *Arch. Pediatrics* 36, 32-6(1919).—The antigen of Miller and that of Petroff were used in the tests. The sera from 17 tuberculous infants and children gave 2 positive and 2 suspicious reactions. Sera from 5 children probably but not definitely tuberculous were negative with both antigens. Sera from 28 non-tuberculous infants and children gave 3 positive and 2 suspicious reactions.

JOSEPH S. HEPBURN.

**Studies in pneumonia. X. Biochemical studies of pneumonia exudates. With special reference to the mechanism of the crisis in pneumonia.** CHARLES WEISS. *Arch. Intern. Med.* 23, 395-407(1919); cf. *C. A.* 13, 473.—Pneumonia exudates contain at least two poisons: (1) specific sensitizing protein identical with pneumotoxin which is liberated on the dissolution of virulent pneumococci and (2) an extremely toxic pyrogenic albumose. There are also present normal serum proteins, albumins and globulins, leucocytes and fibrin. Neither undigested pneumococci protein nor albumin from lung tissue possessing sensitizing powers are demonstrable. The globulin fraction of the human pneumonic exudate is non-toxic and identical with normal globulin while the albumin fraction is toxic and specific. This action is ascribed to the enzymes of the exudate. The albumose fraction is very toxic although a tolerance for it can be established in rats. There were large amts. of ether-sol. substances extd. from the lungs, non-toxic and hemolysis-inhibiting. The formation of exudates is considered to be in part due to increased permeability of the endothelium of the lungs to normal substances. When there is produced an excess of antibodies, etc., the effects of the toxins and albumoses are neutralized and lysis can proceed, producing non-toxic amino acids. When this happens the system comes into equil. and there is a quick change from fever of toxemia to normal condition-crisis.

F. HULTON-FRANKEL.

**Studies on the submaxillary gland. IV. A comparison of the effect of hemorrhage and of tissue-abuse in relation to secondary shock.** ROBERT GESKILL. *Am. J. Physiol.* 47, 468-505(1919).—"Shock is looked upon in a very general way as a combined circulatory and nutritional disturbance mainly of peripheral origin. The condition is initiated by a variety of forms of tissue-abuse which produce tissue damage, transudation of

plasma and stasis of blood. The decreased blood vol., eliciting a vascular constriction, reduces the flow of blood to a level below that essential for normal nutrition and far below that essential for the deteriorated tissues. The condition is thus sustained by a disturbed nutrition and by the consequent inability on the part of the animal to recover the normal permeability of the vessels and therefore restore the normal blood vol. that is essential for an adequate flow." Suggestions for the treatment of shock are made.

J. F. LYMAN.

**The treatment of severe and progressive hemorrhage by intravenous injections.** W. G. PENFIELD. *Am. J. Physiol.* 48, 121-32(1919).—Blood pressure in dogs was maintained at shock level (40 mm. Hg) by progressive bleeding. Considering the condition of the animals according to the duration of low blood pressure, the amt. of blood lost and the degree of acidosis resulting, there was no evidence that gum-bicarbonate soln. or gum-glucose soln. is more efficacious in saving life than is an isotonic NaCl soln. In all fatal cases observed the continued fall of arterial pressure was accompanied, not by a fall of venous pressure, but by a rise. A rise of venous pressure for 20 min. or more accompanying an arterial fall was followed by a fatal outcome regardless of treatment.

J. F. LYMAN.

**The output of epinephrine (adrenaline) in shock.** G. N. STEWART AND J. M. ROGOFF. *Am. J. Physiol.* 48, 22-44(1919).—Shock (low blood pressure), induced in dogs and cats by exposure and manipulation of the intestines, by hemorrhage or by peptone injection, did not affect the rate of output of adrenaline by the adrenals. In detg. rate of output the point is emphasized that rate of blood flow from the adrenals must be considered as well as concn. of adrenaline in the blood of the adrenal veins. Strychnine increased the output of adrenaline.

J. F. LYMAN.

**Some observations upon cases of vomiting in pregnancy.** W. GILLIATT AND E. L. KENNAWAY. *Quart. J. Med.* 12, 61-80(1919).—In some forms of pernicious vomiting a stage is reached when the  $\text{NH}_4$  index of the urine shows a rapid increase in the course of a few days to values between 30 and 50. At this time the acetone substances are being produced in large amts. The term  $\text{NH}_4$  index in this paper denotes the amt. of  $\text{NH}_4$  N of the urine reckoned as a percentage of the total N. In ten women the average  $\text{NH}_4$  index was found to be 5.9 during pregnancy and 4.9 after delivery. In eleven women the av. rise of alveolar  $\text{CO}_2$  tension after delivery was 7 mm. It seems that no explanation has yet been offered of this state of acidosis during normal pregnancy. The changes observed seem too great and sudden to be the result of starvation alone. When this condition appears, abortion seems to be the only treatment which is of any avail, and rapid improvement is to be expected from it in the great majority of cases. Attention is drawn to the great scarcity in the literature of adequate analyses of the urine in this disease, especially in regard to the output of acetone substances. Further differentiation of the various forms of pernicious vomiting is required, since in some recorded cases the  $\text{NH}_4$  index is even subnormal. Such results as have so far been obtained as to the alkali reserve of the blood in pernicious vomiting suggest that  $\text{NH}_4$  is very efficiently utilized in the preservation of this reserve. Thirty-seven references are given.

JOHN T. MYERS.

**An observation upon methemoglobinemia or sulfo-hemoglobinemia.** R. A. JAMIESON. *Quart. J. Med.* 12, 81-7(1919).—A case is reported which illustrates that within a few hrs. some unknown agent may reduce a large % of the hemoglobin to methemoglobin, or an ally, and this agent must, to explain the symptoms, be supposed to introduce itself into the blood stream in considerable amt. and rapidly. The quick and apparently complete recovery points to the introduction being brought speedily to an end. The question of addiction to the use of any drug which might be responsible

for the symptoms displayed was carefully inquired into and proved entirely negative. The altered blood pigment does not appear in the urine; its fate is unknown.

JOHN T. MYERS.

Observations upon the calcium content of the blood in infantile tetany and upon the effect of treatment by calcium. JOHN HOWLAND AND W. McKIM MARRIOTT. *Quart. J. Med.* 11, 289-317(1918).—The various theories as to the pathogenesis of infantile tetany refer it to disease of the parathyroid glands, to the character of the food, to intoxication by Ca, to intoxication by guanidine or methylguanidine, or to the lack of Ca. The evidence at present available fails to confirm the majority of these theories. H. and M. have approached the problem from the standpoint of the Ca content of the blood serum. A method was devised which has shown that the normal Ca content of the serum is from 10 to 11 mg. per 100 cc. In rickets there is a moderate reduction of the Ca in some cases, but in a number of the apparently active cases studied a normal amt. of Ca has been found. In tetany, during the active symptoms, the Ca of the serum invariably is greatly reduced and may fall as low as 3.5 mg. The av. Ca content of the serum in 18 cases was 5.6 mg. In convulsive disorders other than tetany there is no reduction in the Ca of the serum. The cause of the Ca reduction in tetany has not been explained. The inorg. phosphates of the serum are not significantly increased. The Mg of the serum in active tetany is within normal limits. Tetany results at times from the administration of large amts. of  $\text{HNaCO}_3$ . There is no evidence that alkalosis is a factor in the production of infantile tetany. Cathodal hyperexcitability has invariably been accompanied by a marked reduction of the Ca of the serum. Anodal hyperexcitability has been accompanied, in the majority of instances, by a slight reduction of the Ca of the serum. Ca administration produces a prompt effect upon the course of tetany. In a few hours the spasmodic symptoms disappear. The Ca must be continued for a long time.  $\text{CaCl}_2$  administered by mouth causes an increase in the Ca of the serum coincident with the cessation of symptoms, although, in most instances, the Ca of the serum does not return to quite normal figures. The article has a bibliography of 42 references.

MORTON, HENRY H.: *Genitourinary Diseases and Syphilis*. 4th Ed. St. Louis: C. V. Mosby Co. 807 pp. \$7. For review see *J. Am. Med. Assoc.* 72, 1182 (1919).

## H. PHARMACOLOGY.

ALFRED N. RICHARDS.

Colloids and colloid therapy. DUPLAN. *Rev. intern. med. chir.* 28, 46-9(1917); *Abstracts Bact.* 2, 119(1918).—The effects of colloid therapy are of especial interest in septicemias. Expts. demonstrate that when a leucocyte is stimulated to activity by contact with bacterial poisons it absorbs the colloidal particles with which it is placed; the relative soly. of the digested particles almost immediately influences the osmotic tension of the white cell which disintegrates, losing its nucleus or nuclei while its protoplasm dissolves.

JOSEPH S. HEPBURN.

Hemostatic action of gelatin. JUNGO ONO. *Acta Scholae Med. Univ. Imp. Kioto* 2, 271-306(1918).—Gelatin is able to accelerate clotting *in vitro* of blood and of hirudinized blood, but loses this property on long boiling of its soln., or on digestion with trypsin. Substances which agglutinate the blood corpuscles are divided into 4 groups according to the microscopic appearance of the agglutinated mass: (1) Gelatin, gum arabic, fish gelatin (*Colla piscium*), gum tragacanth, and *Althaeae* root. They cause the blood cells to collect in rouleaux which form a network. (2) Sol. starch and agar. These do not produce typical rouleaux but cause somewhat irregular clumping of the cells; inclination to net formation is less marked. The agglutination produced by both

the above groups is detected only microscopically. (3) Abrin, serum of a foreign species, and the globulin isolated from the latter. Microscopically both large and small clumps of corpuscles are produced; the cells are united so firmly that they cannot be separated by shaking; macroscopically a fine ppt. results. (4) Alum,  $\text{CuSO}_4$ , and salts. These do not exert an agglutinating action on a suspension of corpuscles previously freed from serum; microscopically, their action is like that of the third group; but the cells become somewhat smaller; macroscopically the blood becomes somewhat darker, and finally bluish brown. The members of the first 2 groups exert a pptg. action on the blood, approx. proportional to their agglutinative power. Only the members of the gelatin group accelerate coagulation of the blood *in vitro*. When administered subcutaneously, gelatin accelerates pptn. of the blood; it has no such action when introduced into the digestive canal.

JOSEPH S. HEPBURN.

**Antagonistic action of adrenaline and of hypophysis extract on the bronchiae.** B. A. HOUSSAY. *Rev. Assoc. Med. Argentina* 28, 433(1918); *Physiol. Abstracts* 3, 386(1918).—Hypophysis ext. is a bronchio-constrictor. Expts. on guinea pigs demonstrate that hypophysis ext. is always antagonistic to, never synergistic with, adrenaline, which is a bronchio-dilator. The good results obtained in asthma by association of these 2 remedies is to be ascribed to the markedly predominant favorable action of the adrenaline.

JOSEPH S. HEPBURN.

**Action of polonium on the frog-heart, immobilized by potassium-free Ringer solution.** H. ZWAARDEMAKER AND G. GRIJNS. *Arch. néerland. physiol.* 2, 500-4 (1918); *Physiol. Abstracts* 3, 428(1918).—The frog heart was perfused by means of a cannula with Ringer soln. minus its K content, until it ceased beating. It was then exposed to polonium rays, *i. e.*, a Cu plate partially covered with polonium. Out of 33 hearts studied, 19 gave negative results; 4 yielded undoubtedly positive results since the polonium rays restored the automatism. The large % of negative results is ascribed to the weakness of the rays, which were able to act only in favorable cases. Since both positive  $\alpha$  rays from Ra and U and negative  $\beta$  rays from K and Rb have the same effect, it is suggested that the automatism is connected with some colloid which requires a positive or a negative charge to maintain it as a sol or gel.

JOSEPH S. HEPBURN.

**Existence in the animal body of substances which fix the alkaloids.** W. S. v. LEEUWEN. *Arch. néerland. physiol.* 2, 650-7(1918); *Physiol. Abstracts* 3, 460(1918).—If the pilocarpine be removed after each stimulation, its action on the isolated cat intestine can be repeatedly demonstrated. The action of pilocarpine is abolished if it be mixed with macerated rabbit liver. Rabbit serum kept on ice for several days exerted a similar action on pilocarpine. When a mixt. of serum and pilocarpine was treated with dil. HCl and an excess of alc., the entire amt. of alkaloid was recovered; hence, it had been fixed and not destroyed. This conclusion was confirmed by the amt. of active poison remaining at the end of 2 hrs., when increasing amts. of pilocarpine were added to 4 equal portions of serum; the curve, representing the quantity fixed, resembled isotherms of adsorption. The substance in rabbit serum, which rendered pilocarpine incapable of stimulating the surviving intestine of the cat was not cholesterol or lecithin; it probably acted by adsorption of the alkaloid; it or its analog occurs in lesser amt. in the serum of the cat and of the ox, but is absent in that of the dog. Its presence probably explains the difference in susceptibility of the rabbit and cat to pilocarpine.

JOSEPH S. HEPBURN.

**Probable explanation of the Hermann-Straub biological reaction of morphine.** E. C. v. LEERSUM. *Arch. néerland. physiol.* 2, 689-710(1918); *Physiol. Abstracts* 3, 460(1918).—Mechanical or chem. stimulation of the rectum in mice produced an exact imitation of this reaction. The influence of small doses of morphine on the tonus of the

vesical sphincter was studied in narcotized, decerebrated, and decapitated cats, guinea pigs, and rabbits. Intravenous injections of small doses of morphine (2 mg. per kg. of body wt.) increased the tonus of the internal sphincter of the decerebrated cat from a resistance of 15 to 20 cm. to one of 40 cm. of water; the rabbit gave a similar but less marked reaction. Morphine did not reinforce the cramp of the sphincter in the decapitated cat. Hence the excitation probably occurs in the medulla, and stimulation travels by way of the pelvic nerves. The morphine reaction was prevented by section of these nerves, while their mechanical stimulation produced pronounced cramp of the sphincter. The Hermann-Straub reaction is the result of vesical and anal tenesmus.

JOSEPH S. HEPBURN.

**Combined action of narcotics and potassium cyanide on daphne.** F. J. J. BUIJTENDIJK. *Arch. néerland. physiol.* 2, 521-9(1918); *Physiol. Abstracts* 3, 411(1918).—The duration of life of daphne (water-flea) in solns. of certain narcotics (alc., urethan,  $\text{CHCl}_3$ ) was slowly increased with diminishing concn., and rapidly increased at a certain critical concn. Addition of diminishing percents. of KCN to these narcotic solns. produced a gradual increase in the duration of life. Additions of various concns. of alc. to different percents. of KCN also produced prolongation of life. However this inhibition of toxicity of KCN was not definitely established for the change from negative to positive phototropism which occurs when daphne is immersed in 3% and 2% alc. in a chamber, of which only one-half is illuminated. Therefore, the simple theory of Warburg, that the toxicity of KCN is lessened because it is repelled from the surface by the narcotic, probably is inadequate.

JOSEPH S. HEPBURN.

**Scorpions in Korea.** H. MORI. *Chosen Igakukai Zasshi* 16, 47-51(1917); *Jap. Med. Literature* 4, 10-1(1919).—The av. yield of poison from a scorpion was found to be between 0.005 and 0.02 cc.; it contained 74%  $\text{H}_2\text{O}$  and a yellowish cryst. solid; the lethal dose per kg. of body wt. was: on subcutaneous injection 0.0003 to 0.0005 cc. in the rabbit and 0.0001 cc. in the guinea pig, on intraperitoneal injection 0.0005 cc. in the rabbit and 0.0003 cc. in the guinea pig, on intravenous injection 0.0001 to 0.0002 cc. in the rabbit and 0.00005 to 0.0001 cc. in the guinea pig. A 0.1% soln. of the dried poison in saline hemolyzed the erythrocytes of the dog and of the chicken on digestion for 2 hrs. in the incubator or 24 hrs. at room temp., but had no action on erythrocytes from the rabbit, the guinea pig, the cat, and the goat.

JOSEPH S. HEPBURN.

**The blood-coagulating action of gelatin.** H. SCHMERZ AND F. WISCHO. *Mitt. a. d. Grenzgebieten d. Med. u. Chir.* 30, 90-115(1918); *Abstracts of Bacteriology* 2, 253.—Observations on man. The power that gelatin has of hastening blood coagulation is due to the Ca it adsorbs, and is proportional to the amt. of Ca present. Large doses of Ca lactate can be administered intravenously with this end in view without untoward results.

E. H.

**The mechanism of the protection of carbohydrate diet in phosphorus and chloroform poisoning.** J. P. SIMONDS. Chicago. *Arch. Intern. Med.* 23, 362-79(1919).—In P poisoning there is a rapid disappearance of glycogen from the liver. Beginning about the time of the disappearance of the glycogen there occur fatty degeneration and infiltration of the liver, increased protein metabolism, and decreased oxidation. There is a reduction of the intercellular ereptase with little or no change of the esterase content of the liver. The feeding of sugars to P-poisoned animals conserves and replenishes the hepatic glycogen and markedly diminishes the toxic effect of the P. The available data on chloroform and P poisoning, acute yellow atrophy of the liver, and eclampsia tend to show that the differences between the changes produced by P poisoning and the others are quantitative rather than qualitative. It has been suggested that an adequate supply of glycogen may affect the state of the colloid of the cell (1) by stabilizing

the emulsion and preventing its "breaking" with the throwing out of droplets of fat, and (2) by reducing the permeability of the cells to the poison. There is reason to believe that if carbohydrate is not supplied in the diet, it is obtained by breaking down of protein. In P poisoning there is a diminution of the power of the body to carry on its normal oxidative processes and at the same time an increased demand for readily oxidizable material. Since fat is more difficult to oxidize than carbohydrate it cannot supply this need. The liver tends to meet this increased demand by the transportation of fat which it cannot oxidize and by increased protein metabolism. The liver is better able to burn its own glycogen than most other substances supplied to it. Autolysis proceeds more rapidly in those livers that are glycogen-free from starvation, P poisoning or action of thyroid ext. Autolysis occurring in P poisoning is supposed to be due to reversed enzyme action. The administration of sugar replenishes the glycogen of the liver and is believed to protect the animal against P poisoning (1) by effect on the colloids of the cell, (2) by furnishing carbohydrate which seems to be essential to normal synthetic processes of protein metabolism, (3) by supplying in the most easily oxidizable form material to an organ where oxidation has been decreased by poisoning, (4) by inhibiting the process of autolysis *in vivo*, (5) by preventing the reversal of the enzyme action. The author believes that the facts justify the therapeutic use of sugar in P and chloroform poisoning, in acute yellow atrophy of the liver and possibly in eclampsia.

F. HULTON-FRANKEL.

**Dyestuffs as medicinal agents.** G. HEYL. *Color Trade J.* 4, 73-6(1919).—About 200 of the dyes known to commerce have been tested as to their therapeutic merits in addition to a few specially prepared to answer certain biological requirements. The majority of these have failed to give results. Ehrlich holds that parasites are degenerated or killed only by those chemicals (dyes) to which they are related; these are termed "parasitotrope." At the same time chemicals (dyes) related to human organs are also poisonous to the human body and are called "organotrope." Dyes can only be used for sterilizing purposes when both parasitotropy and organotropy are in proper equilibrium. Most dyes used for direct introduction into the blood are built up from benzene and Ehrlich holds that for therapeutic purposes the poison group should be attached at the top and the antidote group to the bottom of the ring. Toxicity of dyes may be due to presence of poisonous metals, as for instance As in early types of magenta, or to its especially astringent properties, besides the staining effect upon tissues. A dye that is astringent is also of low diffusibility, and this brings about acute congestion, coma and perhaps death. The first and most important property of a medicinal dye used for internal therapy is that after having done its work on the bacillus it be diffusible. Such dyes are called "eutherapeutic;" all others are named "dytherapeutic." H. gives a list of both types of dyes, with a classified table of their uses.

L. A. OLNEY.

**Selection of a type of "pe-gya" bean (*Phaseolus lunatus* var.) with a low hydrocyanic acid content, in Burma.** F. J. WARTH AND KO KO GYI. *Bull. Agr. Res. Inst. Pusa* 79, 11 pp.(1918); *Bull. Agr. Intelligence* 9, 1311.—The object of the work was to isolate strains or types of the Burma bean poor in HCN, so as to avoid poisoning attributed to this bean by London firms. After extn. of the glucoside with alc. the HCN was detd. as Prussian blue either colorimetrically or gravimetrically after ignition to  $\text{Fe}_2\text{O}_3$ . The HCN content of the parent seed varied from 0.0004 to 0.0347%. Results on one generation grown under varying climatic conditions varied from 0.0008 to 0.0325% HCN. The authors conclude that the HCN content of the bean is an inherited character which remains fairly const. in the descendants, and that there is no relation between the color of the seed and its HCN content.

T. G. PHILLIPS.

## I. ZOÖLOGY.

R. A. GORTNER.

**Phagocytosis and resorption in *Helix pomatia*.** H. J. JORDAN. *Arch. néerland. physiol.* 2, 471-6(1918); *Physiol. Abstracts* 3, 410(1918).—A ration of bread and milk, colored with powdered carmine, was fed; and the animal was killed from 24 to 48 hrs. later. The intestinal glands were colored red; and microscopic examn. showed the presence of carmine granules in large vacuoles in practically all the "resorption" or liver cells. Diffusion to a slight extent occurred when the ligatured esophagus and intestine were placed in Ringer soln. and were filled with glucose soln. isotonic with the blood, and *vice versa*. Diffusion is considered the basis of absorption; the resorption cells produce chem. changes in the direction of pptn., *e. g.*, sugar becomes glycogen. "For the first time phylogenetically in *Helix* the bowel wall is pressed into the service of nutrition as a diffusion membrane. In the higher animals, aided by the activity of the resorbing cells, it supplants the primitive method of phagocytosis."

JOSEPH S. HEPBURN.

**Physiological study of luminescence of *Watasenia scintillans* (Berry).** R. SHÖJL. *Am. J. Physiol.* 47, 534-57(1919).—See C. A. 12, 956. J. F. LYMAN.

**Carbon dioxide production during starvation in *Planaria*.** C. M. CHILD. *Am. J. Physiol.* 48, 231-57(1919).—Rate of  $\text{CO}_2$  production was detd. by change in  $p_{\text{H}}$  value of the water in which the *Planaria* grew. Starvation in *Planaria* produces, during the first few days, a rapid decrease in rate of oxidation, this continuing to decrease more slowly for several weeks, but in the advanced stages of starvation increasing. In starvation the activity of the ectoderm and body wall increases while that of the alimentary tract decreases. There is evidence that animals reduced by starvation and then fed are physiol. younger than at the beginning of starvation. J. F. LYMAN.

**Quantitative studies on the rate of respiratory metabolism in *Planaria*.** I. The effect of potassium cyanide on the rate of oxygen consumption. G. D. ALLEN. *Am. J. Physiol.* 48, 93-120(1919).—KCN added to the water containing *Planaria agilis* reduces the O consumption of the latter, *e. g.*, to 30% of the normal rate in 0.0002 M KCN. The max. effect of the KCN is almost immediate and does not change materially with time. On removal from KCN soln. the worms rapidly recover their normal level of oxidation. Lowered oxidation could not be attributed, to any large extent, to the cessation of movements due to the anesthetic effect of the KCN. There appeared to be a residual oxidation of about 20% of the normal which could not be affected by KCN. Winkler's method for O detn. was employed. J. F. LYMAN.

**Calcium in normal physiology of Phasmodae (Ins. Orth.) eggs and hatched larvae.** *Compt. rend.* 168, 127-9(1919).—Ca is present in the shells of the eggs as carbonate; it is not uniformly distributed in the shell but is mostly in a cryst. layer generally distinct from the internal wall of the exochorion. The conclusions are in accord with those of Clarke and Wheeler (C. A. 11, 1941) that the calcite is in the form of aragonite. Carbonates are absent in the egg mass, the abundant Ca being present partly as phosphate and partly in org. combination. That a large amt. of Ca is in org. combination is proved by hatching the eggs when the Ca accumulates in the Malpighian tubes as phosphate (cf. following abstr.). L. W. RIGGS.

**Reserve calcium in the female of Phasmodae; its forms of elimination in both sexes.** J. PANTEL. *Compt. rend.* 168, 242-4(1919); cf. preceding abstract.—The  $\text{CaCO}_3$  as existing in the inferior Malpighian tubes of female *Phasmodae* consists principally of spherules showing as a milk-white mass by reflected light, or colorless and brilliant by transmitted light. It is quite sol. in water, more sol. if heated, and still more sol. in solns. made alk. with KOH, NaClO,  $\text{Na}_2\text{CO}_3$ , etc. It is deposited from these solns.

generally as spherocrystals, sometimes as isolated rhombohedra. Maceration in a reduced quantity of the solvent easily brings about the entire transformation of the  $\text{CaCO}_3$  from spherules to rhombohedra. Something like this takes place in the formation of the egg shell. In both sexes Ca is eliminated principally as phosphate,  $\text{CaHPO}_4$ . In hatched larvae the phosphate is sometimes accompanied by a small amt. of uric acid or urates.  $\text{CaC}_2\text{O}_4$  has been found in the Malpighian tubes of both sexes of *Phasmidae*.

L. W. RIGGS.

**Glycogen in the chick embryo.** H. JEANETTE ALLEN. *Biol. Bull.* 36, 63-7, plates 2(1919).—"Glycogen was almost invariably present in the yolk sac from the earlier stages to chicks of 10 days." It gives to the walls of the blood vessels of this region a striking red color and under high power appears as mahogany-colored masses scattered among the cells. The progress of glycogen formation is traced in detail and illustrated by drawings. The results show "that in the chick the storage of glycogen in the embryonic tissue itself is not as extensive as in other forms, and that it does not become a well-developed function of the embryo in its earliest stages, though glycogen does appear in some of the tissues and becomes more and more abundant in later stages. The embryo depends for its energy production and building material upon the food of the yolk, a part of which is kept on hand in the form of glycogen in the yolk sac."

L. W. RIGGS.

**Demonstration of the axial gradients by means of potassium permanganate.** C. M. CHILD. *Biol. Bull.* 36, 133-47(1919); cf. *C. A.* 11, 1848, 2700, 3303.—"The use of permanganate is based on the assumption that the rate of reduction of permanganate and the consequent coloration of the protoplasm may be expected to show some relation to the physiol. condition of the parts concerned, as regards their metabolism, oxidative ability, reducing capacity or avidity or demand for O, in short to some of the essential factors concerned in the protoplasm gradients." The author used concns. ranging from 0.001 *M* down to 0.00001 *M*, most of the work being done with a concn. of 0.0001 *M* ( $M = 316$ ). The results have not only confirmed the results of the susceptibility methods, so far as the same forms have been used, but in many cases the great delicacy of the staining reaction has brought out very clearly differences not shown in the susceptibility methods with lethal concns. The results showed "that regions of high oxidation rate are most rapidly or most deeply stained in permanganate and also show the highest susceptibility as regards death and disintegration of the protoplasm in the proper concns." Summarizing the author states that "the axial gradients in many plants and animals can be very clearly and beautifully demonstrated as color gradients by the use of low concns. of  $\text{K}_2\text{Mn}_2\text{O}_8$ , the color being due to the reduction of the permanganate to  $\text{MnO}_2$  by protoplasm. Axial gradients have been demonstrated by this method in all axiate organisms thus far examd. including several algae, a diatompseudothallus, four species of protozoa, various hydroids, hydromedusae and their developmental stages, a siphonophore, actinians, developmental stages of polyclads and echinoderms, axiate appendages of polychetes, and ascidian tadpoles."

L. W. RIGGS.

**Reversibility of the heliotropism of Arenicola larvae by chemicals.** SAKYO KANDA. Kyushu Imperial Univ. *Biol. Bull.* 36, 149-66(1919).—"The free swimming larvae of *Arenicola cristata*, just after they leave the egg strings at the swarming stage, are strikingly positive to light, and were used in this study. At each trial four 100-cc. beakers were used as follows: One for control with normal sea  $\text{H}_2\text{O}$  at room temp., a second with treated sea  $\text{H}_2\text{O}$  at room temp., a third with treated sea  $\text{H}_2\text{O}$  at higher temp., and a fourth with treated sea  $\text{H}_2\text{O}$  at lower temp. Fifty cc. of liquid were used in each beaker and the beakers were set in finger bowls containing sea  $\text{H}_2\text{O}$  of the same temp. as the beaker. When all beakers were ready and fairly constant at the desired temps., larvae

were added as uniformly as possible with a pipet to each beaker. Light was admitted from one window and reflection cut off by black cloth placed behind and under the beakers. The following summary is given: At room temp. nearly all *Arenicola* larvae in the early swarming stage in normal sea  $H_2O$  are positively heliotropic. At temp. of  $30-34^\circ$  about half of the larvae became negative to light after about 5 min. of exposure. In sea  $H_2O$  made hypertonic by addition of  $NaCl$  or  $KCl$ , 20 to 35% became negative. In sea  $H_2O$  made hypertonic with  $CaCl_2$ ,  $MgCl_2$  or  $MgSO_4$  no reversal was observed. In hypotonic sea  $H_2O$  about 90% of the larvae reversed their heliotropism; reversal takes place more rapidly the higher the temp. (between  $12$  and  $32^\circ$ ). Isotonic solns. of  $NH_4$ ,  $K$ ,  $Li$ ,  $Na$  chlorides and sulfates made in sea  $H_2O$  reverse the positive heliotropism of the larvae. But isotonic solns. of  $Ca$  and  $Mg$  chlorides and sulfates in sea  $H_2O$  do not. The reversing effect of these salts seems, therefore, due to the cations. This suggests an action on the plasma membranes (cf. the membrane theory of Ostwald-Bernstein, *Arch. ges. Physiol. Pfluger's* 122, 129). The effective order of these cations is  $Na < Li < K < NH_4$ . In artificial sea  $H_2O$ , the positive heliotropism of the larvae is not noticeably different from that in natural sea  $H_2O$ . A trace of alkali makes apparently no difference. Hypertonic  $NaCl$  and  $KCl$  solns. added to the artificial sea  $H_2O$  reversed the positive heliotropism of the majority of the larvae. In  $Na$ -free artificial sea  $H_2O$ , the larvae became motionless immediately after treatment (effect of hypotony). In  $K$ -free artificial sea  $H_2O$ , many became negative to light, and remained at the bottom of the negative side of the beaker. In  $Ca$ -free artificial sea  $H_2O$ , the larvae became motionless about 15 min. after the exposure.  $Mg$  alone, therefore, cannot antagonize the toxic action of  $Na$  and  $K$  salts. In  $Mg$ -free artificial sea  $H_2O$ , many remain positive to light. This fact may be explained as an antagonistic action of  $Ca$  towards  $Na$  and  $K$  salts which acting by themselves are negativating agents. Alcohols ( $Me$ ,  $Et$ ,  $n$ - $Pr$ ,  $n$ - $Bu$ ) as used in these expts. were not favorable as negativating agents at room temp., though they are good at higher temp. The higher the alc. in the series the greater is its negativating effect. Most larvae treated with  $MeOAc$  or  $EtOAc$  became negative at higher than room temp. Other compds.,  $CHCl_3$ ,  $HCHO$ , ether and saponin, produced little or no reversal while the larvae were in the solns. except saponin at higher temps. Monobasic fatty acids are the best of all chemicals used for this work. The higher the acid in the series the greater is its negativating effect. Some narcotics "antagonize" or retard the reversing action of butyric acid. The reversing effect of a very weak concn. of butyric acid ( $0.00006 M$ ) in artificial sea  $H_2O$  is great.  $HCl$  and  $H_2SO_4$  produce negative heliotropism almost as well as fatty acids. In producing negative heliotropism  $NH_4OH$  is much more efficient than strong bases. *Arenicola* larvae treated with narcotics become negative after returning into normal sea water.

L. W. RIGGS.

## 12. FOODS.

W. D. BIGELOW AND F. F. FITZGERALD.

Review of food laws enacted during 1918. *Am. Food J.* 14, No. 1, 24-5(1919).—  
A summary of federal and state enactments. F. POWDERMAKER.

Model egg law. *Am. Food J.* 14, No. 2, 32(1919).—The law was drawn up by food and drug control officers of the various states, representatives of the Bureau of Chemistry, the Food Administration, the State Poultry and Egg Shippers' Association and the executive committee of the National Poultry, Butter and Egg Association.

F. POWDERMAKER.

Report for 1917 of the provincial laboratory at Groningen for the analysis of food and other products. *Chem. Weekblad* 16, 145-55(1919).—In addition to routine

analyses, problems connected with the fish industry were studied. The "ripening" of salted anchovies was found to be due to a tryptic enzyme, detected by the formation of tyrosine, tryptophan and other amino acids from the albumin of the fish. Crustaceae in fish meal can be detected by the presence of chitin, which does not occur in fish. Attempts to pickle herring from the Zuider Zee were unsuccessful, because these fish lack the enzyme action which makes other herring tender when pickled. The enzyme is present, but is rendered inactive by an anti-enzyme. JULIAN F. SMITH.

**Micro-colorimetric method for the identification of wheat, rye, and potato starches in the presence of each other.** E. UNNA. *Z. Nahr. Genussm.* 36, 49-53(1918); *J. Soc. Chem. Ind.* 37, 746A.—Ten g. of the flour are steeped in 3% phenol soln. for 24 hrs., and a small portion is then transferred to a microscope slide and air-dried for 30 min. It is then treated with a mixt. of 1 g. of water-blue-orcin soln. (water-blue 1, orcin 1, glacial acetic acid 5, glycerol 20, alc. 50, and water 100 parts) and 6 drops of 1% eosin soln. (in 60% alc.); after 10 min., the prepn. is washed with water, treated for 20 min. with 1% safranin soln., again washed with water, and treated for 30 min. with 0.5%  $K_2Cr_2O_7$  soln. The prepn. is finally washed with water, alc., and xylene, mounted in Canada balsam, and examd. under the microscope. Potato starch is colored bright red, while wheat and rye starches are brownish yellow, the rye being darker than the wheat. Gluten is colored bright blue. E. J. C.

**Analysis of egg powder.** L. GARNIER. *J. pharm. chim.* 18, 353-7(1918).—A specimen of com. egg powder was light yellow, had a not unpleasant odor and taste, and showed absence of starch and sugar. Analysis per 100 g. gave  $H_2O$  8.99, org. matter 87.43, sol. ash ( $P_2O_5$  abundant) 1.55, insol. ash ( $P_2O_5$  and  $CaO$  abundant) 2.03 g. Total N was 7.83, total  $P_2O_5$  1.097,  $P_2O_5$  of lecithin 1.8123; oil of egg (fat + lecithins + lutein) 45.878 g., fat + lutein 25.32, (distearic, lecithin  $C_{44}H_{88}PNO_8$ ) 20.56 g., proteins (by difference) 41.55 g. However, when calcd. protein from total N less that of lecithin, then multiplying by the factor 6.33, the protein % of 47.28 is obtained, which agrees better with the Jürgensen ratio of 13:11 for protein: fat (in table quoted from Jürgensen, Copenhagen, *per cent. composition of human food*). G. concludes that the com. product examd. is of good quality. On the basis of 25% egg solid (Jürgensen) an av. of 58 g. total wt. (Gautier), of which 1% is shell and membranes, he calcd. that 1 hen egg corresponds to 15 g. of this powder and 1 kg. of the powder is equiv. to 66 eggs. S. WALDBOTT.

**Tests of storage and fresh eggs.** HERMAN C. LYTHERG. Mass. State Board of Health. *Am Food J.* 14, No. 1, 15(1919).—The eggs were candled and the  $NH_3$  was detd. Strictly fresh eggs contain less than 1 mg.  $NH_3$  per 100 g. of egg, reasonably fresh eggs contain as much as 2 mg. and decompd. eggs contain more than 4 mg. During Dec., 1917, and Jan. and Feb., 1918, 133 samples of eggs sold as fresh eggs and 100 of those sold as storage eggs were examd. It was found that if one asked in a retail store for cold storage eggs, the chances were 1 to 6 of getting fresh eggs. If fresh eggs were asked for the chance were even that the eggs would be of the same quality as cold storage eggs. F. POWDERMAKER.

**Behavior of various substances as preservatives of milk.** H. MOHORCIC. *Arch. Hyg.* 86, 254(1917); *Chem. Ztg.* 42, 189(1918); *J. Soc. Chem. Ind.* 38, 50A.—While the addition of Na salicylate, Na benzoate, benzoic acid, boric acid, borax,  $Na_2CO_3$ , or  $CH_3O$  retards the formation of acid in milk, so much acid is formed eventually that the milk curdles. Frequently, a higher acidity is necessary to curdle preserved milk than is required to curdle untreated milk. E. J. C.

**What do we mean by the term "standardized milk?"** I. L. VAN SLYKE. *Am. Food J.* 14, No. 3, 10(1919).—Standardized or adjusted milk is milk changed by the re-

removal of fat, thus decreasing the ratio of fat to solids not fat, or milk to which cream is added, causing an increase in the ratio of fat to solids not fat. Van S. recommends that if standardization is permitted, special licenses should be required, a minimum composition required, the % of fat stated on the label and conditions prescribed to prevent the impairment of the sanitary quality. F. POWDERMAKER.

**Milk conserves.** BALLAND. *J. pharm. chim.* 18, 363-5(1918).—Analyses of samples for army use in the Orient show the compn. to be very variable. Certain milk powders contain only traces of butter fat, others have sugar added. They slowly take from the air from 10 to 18% of  $H_2O$ . Cond. milks show even greater anomalies: 24 to 75%  $H_2O$  and up to 45% of cane sugar. Analytical results on 12 samples of cond. milks of various origin are given. Those on 4 samples of dried milks of American, English, French and Dutch are, resp., as follows:  $H_2O$  6.44, 6.11, 5.80, 8.54%; total solids 93.56, 93.99, 94.20, 91.46%, of which butter fat is 0.80, 11.18, 10.00, 0.50%; casein 26.87, 9.46, 31.50, 33.50%; lactose 32.80, 59.00, 33.76, 46.00%; sucrose 0.00, 0.00, 8.14, 0.00%; ash 5.68, 3.60, 6.75, 8.04%. S. WALDBOTT.

**The analysis and evaluation of buttermilk porridge.** J. D. FILIPPO. *The Hague. Chem. Weekblad* 16, 41-4(1919).—Buttermilk porridge is made from steamed barley and buttermilk. The *Codex alimentarius* requires that 1 l. of the porridge shall contain 0.8 of the solid constituents of 1 l. of good quality buttermilk, but makes no provision for judging as to whether the requirement has been met. For this purpose, the most significant properties are the casein content and the optical rotation. Casein is best isolated by warming with NaOH soln., with addition of sufficient 1% Na oxalate soln. to prevent any free casein from remaining in the hydrosol state. After centrifuging and pptg. with 0.5 *N*  $H_2SO_4$  and EtOH, the free casein is allowed to settle, filtered off, washed with 50% EtOH and detd. by the Kjeldahl method. The porridge should contain not less than 1.8% casein, and its rotation should be at least  $2.7^\circ$  per 100 g. JULIAN F. SMITH.

**Detection of milk in pastry.** J. GROSSFELD. *Z. Nahr. Genussm.* 35, 457-71(1918); *J. Soc. Chem. Ind.* 37, 712A.—The method proposed depends on the conversion of lactose into mucic acid. 50 g. of the sample are shaken with 500 cc. of water, filtered and 250 cc. of the filtrate evapd. to a thin sirup with the addition of 5 cc. of glacial AcOH; the sirup is treated with 100 cc. of warm 90% alc., the mixt. filtered, and the filtrate evapd. to dryness. If a large quantity of sucrose is also present, this dry residue must be dissolved in 100 cc. of alc., 100 cc. of ether added, the pptd. sugars collected after 24 hrs., and again treated with alc. and ether. In this way the lactose is cond. in the ppt. and the greater part of the other sugars removed. The pptd. lactose is heated for a short time on a water bath with 30 cc. of  $HNO_3$  (sp. gr. 1.15), the soln. filtered and the filtrate placed aside; mucic acid usually crystallizes out within 24 hrs., but may require several days. The mucic acid obtained melts at  $200-210^\circ$ , and each g. requires 9.5 cc. of *N* NaOH for neutralization. About 30% of the lactose present is converted into mucic acid. The Ca oxide content of pastry may also afford some indication as to whether milk has been used in its prepn.; pastry made without milk may contain up to 0.2% Ca oxide (calcd. on the dry substance); the presence of milk increases this quantity, but, especially if the Ca oxide content exceeds 0.35% the increase may be due to ingredients other than milk. E. J. C.

**Caffetannic acid a bugaboo.** CHARLES W. TRIGG. *Tea and Coffee Trade J.* 33, 437-9(1917).—A general consideration of caffetannic acid and the official methods of analysis. Inaccuracies and lack of significance of analysis are pointed out and recommendations are made for change of nomenclature. A bibliography is included. C. W. T.

**Caffeine-free coffee.** CHARLES W. TRIGG. *Tea and Coffee Trade J.* 34, 233-5 (1918).—A consideration of natural and prepd. caffeine-free coffees, their physiol. effects, etc. Caffeol tends to counteract the effects of caffeine. Caffeine-free coffee has a depressant action.  
C. W. T.

**The aroma of coffee.** CHARLES W. TRIGG. *Tea and Coffee Trade J.* 35, 37-9 (1918).—Differences in coffees are largely due to caffeol, which is a mixt. of destructive distn. products. Caffeols of various coffees have different compn. Physiol. effect is discussed and bibliography is given.  
C. W. T.

**Coffee oils and fats.** CHARLES W. TRIGG. *Tea and Coffee Trade J.* 35, 230-1 (1918).—Compn. of coffee oil is taken up. There is no essential oil in coffee. Fat serves to retain aroma in the bean, and its decompn. products form aromatic constituents.  
C. W. T.

**Coffee carbohydrates.** CHARLES W. TRIGG. *Tea and Coffee Trade J.* 36, 246-7 (1919).—Discussion of nature of carbohydrate content of coffee, and carbohydrates used in adulteration and prepn. thereof.  
C. W. T.

**Vinegar samples.** CHAS. W. BROWN. *Michigan Agr. Expt. Station Report* 1917, 272-4.—Analyses are given of various samples of vinegar that have been sent to the Station by farmers who have had trouble in making vinegar. The chief causes of trouble were found to be due (1) to disease, or growth of a group of bacteria in the must, favored by the use of unsound fruit, by extremely low acidity in the must, and by a tardy alcoholic fermentation; (2) to the presence in the must of high acidity which retards or prevents the work of the yeast, and which was brought about by placing the fresh juice in casks containing a quantity of vinegar; and (3) to an insufficient supply of free O for the vinegar bacteria on account of the casks being full or nearly full, and the opening completely or partly closed.  
W. H. ROSS.

**Cider- and vinegar-making qualities of Minnesota apples.** W. G. BRIERLEY. *Minnesota Agr. Expt. Station Report* 1917, 55-7.—Analyses of samples of cider show that the sugar content of Minnesota apples is not high, necessitating careful work in the prepn. and handling of the cider to be used in making vinegar. Holding weak vinegar in casks more than 5 or 6 months does not insure greater strength but often results in peculiar changes and an actual loss of strength. It is shown that cider capable of producing vinegar of standard strength will do so regardless of modifications in the fermentation procedure, if kept at ordinary room temp. under the usual methods for cask fermentation; and that cider which under ordinary conditions will not produce a standard vinegar seemingly cannot be made to develop into a standard vinegar by any common method of treatment. A list is given of the varieties of apples best suited for making sweet cider or vinegar.  
W. H. ROSS.

**Fruit juices.** FIRMAN THOMPSON. Delaware Agr. Expt. Station, *Bull.* 119, 18-9 (1918).—A report is given of a preliminary investigation on the sepn. and detn. of citric, malic and tartaric acids in fruit juices. Detns. of the H-ion concns. of the juices of ripe fruits were found to give results which were very nearly of const. value. Preliminary observations on the H-ion concns. of fruit juices at different stages of maturity also indicated surprisingly const. results which varied much less than the total or titrated acidity. This constancy of acid concn. is probably necessary for the purpose of enzyme activity.  
W. H. ROSS.

**The chemical composition of the pineapple and the materials necessary to its cultivation.** J. V. GONCALVES DE SOUSA. *Rev. Agron.* (2) 13, 26-31 (1918); *Bull. Agr. Intelligence* 9, 1200.—Results of the analysis of the whole fruit are as follows: moisture 86.78, fat 0.11, protein 0.8, fiber 0.62, ash 0.44, N-free ext. 11.22%. The K content is 0.196%. Analyses of the cultural layer, mold, etc., confirm the view that

this plant requires large amts. of K, and of N in the form of org. matter. The food removed from the soil by each 1000 plants, the fruit and plant each averaging 2 kg., is N 8.1 kg.,  $P_2O_5$  0.84 kg., K 17.5 kg., CaO 2.68 kg.

T. G. PHILLIPS.

**Brake-fern** (*Pteris aquilina*, L.) as a source of starch. A. ZLATAROFF. *Z. Nahr. Genussm.* 35, 483-4 (1918); *J. Soc. Chem. Ind.* 37, 712A.—Eleven kg. of washed and dried brake-fern roots yielded 7.6 kg. of meal, which contd.: water 8.04, starch 46.00, cell tissue 22.11, ash 10.48%. The meal had a gray color and a bitter taste, but the latter might be removed by washing and sedimentation; it appears to be more suitable as a cattle food than for bread-making.

E. J. C.

The treatment of lupines in order to eliminate their toxic properties; researches in Holland. BOODR. *Tydschrift der Nederlandsche Heidemaatschappij* 30, 68-70 (1918); *Bull. Agr. Intelligence* 9, 1210.—The lupines are covered with water and let stand 24 hrs. They are then placed in a vat of fresh water, boiled 3 hrs., and left 12 hrs. to cool. They are then removed to another vat and soaked in fresh water 12 hrs. Finally they are crushed with a wooden mallet. Cattle are not able to digest the lupines readily. Mixing with finely chopped oats straw increases their digestibility. For working oxen 22 lbs. per week per head suffice. If no concentrates are used this quantity may be doubled or trebled. The starch value for the lupine is 74.2.

T. G. PHILLIPS.

**Fruit conserves.** BALLAND. *Bull. sci. pharmacol.* 25, 344-8 (1918).—A report on the moisture, and total and reducing sugar content of various preserved fruits purchased in the French market.

F. S. HAMMETT.

The products obtained from the seed of the field mustard. ROTHEA. *Bull. sci. pharmacol.* 26, 16-20 (1919).—Analysis of the whole seed of the field mustard (*Brassica arvensis*) gave  $H_2O$ , 8.14%; ash, 4.70%; N, 21.85%; fat, 25.82%; cellulose and hydrocarbons, 39.49%; allyl isothiocyanate, 0.18%. This seed is pharmaceutically low in allyl isothiocyanate and high in fats. The seeds treated in an oil-press gave crude oil, 15.8%; oil cake, 80.8%; wastage, 3.4%. The oil cake had  $H_2O$ , 9.24%; ash, 5.49%; N, 27.31%; fat, 14.34%; sugars, 1.95%; hydrocarbons, 41.76%; and allyl isothiocyanate, 0.21%. The sp. gr. of crude oil was 0.9146, of filtered oil 0.9144; the color was brown; odor, agreeable; acidity in terms of oleic acid, crude oil 0.71%, filtered oil 0.76%; I no. 104.9; sapon. no. 177.7; acetyl no. 15.3;  $n_D^{22}$ . It can be used as a condiment.

F. S. HAMMETT.

Investigations into the composition of seaweeds with a view to their utilization as cattle food, in the Netherlands. B. R. DE BRUYN. Wageningen. *De Veldbode* 807, 504-5 (1918); *Bull. Agr. Intelligence* 9, 1213.—On a water-free basis compn. of *Zostera marina* is: albuminoids 20.6, true albumin 16.9, digestible albumin 4.2, fat 1.6, starch 38.6, crude fiber 14.8, ash 24.4, and NaCl 12.7%. Samples of *Fucaceae* were also analyzed. B. did not find tannic acid, which has been supposed to reduce the digestibility of the proteins. Before drying, salt must be washed out with soft water. Algin, a mucilaginous, nitrogenous substance occurring in many seaweeds, forms with Ca and Mg insol. compds. which would diminish the food value if hard water were used.

T. G. PHILLIPS.

**Leucaena glauca.** ANON. *Dep. Agr. Ceylon Leaflet* No. 7, 4 pp. (1918); *Planters' Chronicle* 13, 201-3; *Bull. Agr. Intelligence* 9, 1197-9.—This is a small leguminous tree, a native of tropical America, now widely distributed in southern Asia and the neighboring islands. It grows rapidly, and is used as a green manure crop, as a source of fuel and as a light shade for coffee and forest plantations. The leaves are rich in N and K and are eaten readily by cattle. The seeds are rich in N, and a valuable

food for cattle, but should not be fed to horses, as they cause an irritation of the skin. Several analyses of the seed are given. T. G. PHILLIPS.

Wood cellulose as fodder in Sweden. C. G. SCHWALBE. *Papier-Zig.* 43, 318 (1918); *J. Soc. Chem. Ind.* 38, 51-2A.—Feeding trials have been made with wood cellulose, previously treated with small quantities of acid, in order to make it tender and destroy the felting capacity of the fibers. The expts. showed a very high digestibility but a tendency to give rise to kidney irritation. The unfavorable results may be explained by the various forms in which wood cellulose is prepd. for fodder. S. points out that if the chem. treatment is not carried out correctly, undesirable side reactions may occur, with the formation of small quantities of MeOH, CH<sub>2</sub>O, formic acid, or AcOH, which are not in themselves injurious to the cattle but yet may lower the digestibility of the fodder. E. J. C.

Chemical and physical changes in apples during the ripening and storage period (SNYDER) 11D. African oil-yielding plants (PIERRAERTS) 27. Influence of temperature and hydrogen-ion concentration upon the spore cycle of *Bacillus subtilis* (ITANO, NEEL) 11C. Edible fungi (KOBERT) 11C. The feeding of troops (ANON.) 11E.

HUNZIKER, OTTO F.: *Condensed Milk and Milk Powder. Prepared for Use of Milk Condenseries, Dairy Students and Pure Food Departments.* 2nd Ed. Revized and enlarged. Lagrange, Ill. 350 pp. \$5.00.

TIJMSMA, S. AND WAAL, D. C. DE: *Onderzoek naar een verband tusschen het vetgehalte vande droge stof van kaas, het vetgehalte der kaasmelk en het oorpronkel i j k vetgehalte van de volle melk.* Friesland: Bond van Coöperatieve Zuivelfabrieken. 180 pp. For review see *Chem. Weekblad* 15, 112(1918).

Flour, etc. E. C. SUTHERLAND. *Brit.* 121,943, Sept. 12, 1918. Before treating flour, meal, or the like with a peroxide as described in 102,967, there is added to the flour or meal a substance contg. active Cl or a small quantity of free Cl to render inactive the enzymes which are able to decompose H<sub>2</sub>O<sub>2</sub>. As a substance contg. active Cl, CaOCl<sub>2</sub> may be used. As examples of materials to which the process may be applied, potato flour, rice flour, starch, manioc root, meals rendered wholly or partially sol. or dextrinized, and dextrin itself are mentioned.

## 14. WATER, SEWAGE AND SANITATION.

EDWARD BARTOW AND W. F. MONFORT.

Boiler-water treatment. *Bur. of Mines, Tech. Paper* 218, 8 pp.(1919).—This is a reprint of *Eng. Bull.* No. 3, prepd. by the U. S. Fuel Administration. The subject is discussed from the point of view of the reduction in factory heat losses by the avoidance of boiler scale. E. J. C.

Impurities in boiler water. F. F. VATER. *Power Plant Eng.*, Jan. 1, 1919, 39 pp.—A complete discussion of impurities in boiler water, their harmful effects and qual. and quant. tests. C. H. ELDRIDGE.

Water-softening plants. C. E. STROMEYER. *J. Soc. Chem. Ind.* 38, 49-50R (1919); *Water and Water Eng.* 21, 34-7.—Reviews of the permutite process and of the lime-soda are given. The lime-soda process is dependent on three factors: temp., time, and contact. The tendency of softened water to cause corrosion is attributed to the coexistence of NaCl, Na<sub>2</sub>CO<sub>3</sub>, and dissolved air in the water. Slight excess of

$\text{Na}_2\text{CO}_3$  or addition of tannin to feed water acts as a preventative. No corrosion was detected where permutite-treated water was used. M. C. PERRY.

Color of water. WILDER D. BANCROFT. Cornell Univ. *J. Franklin Inst.* 187, 459-85(1919).—Second and final installment of this paper. Cf. C. A. 13, 881.

JOSEPH S. HEPBURN.

Determination of magnesia in water. M. MONHAUPT. *Chem. Ztg.* 42, 338 (1918); *J. Soc. Chem. Ind.* 37, 558A.—A few drops of methyl orange soln. are added to 100 cc. of the water, the latter is neutralized in the cold, 5 cc. of 3% K oxalate soln. and a known excess of 0.1 N alkali soln. (equal vols. of 0.1 N NaOH and  $\text{Na}_2\text{CO}_3$  solns.) are added, and the mixt. is dild. to 200 cc. The quantity of NaOH added must be more than that of the magnesia present in the water. After filtration, 100 cc. of the filtrate is treated with 5 cc. of 2% neutral  $\text{CaCl}_2$  soln. and then titrated, without filtration of the Ca oxalate and carbonate, with 0.1 N acid. E. J. C.

Critical study of the bacterial count in water and sewage. M. F. STEIN. *Am. J. Pub. Health* 8, 820-9(1919).—A study of bacterial methods in the light of the theory of probabilities. The expected error is given expression in formula. 200 to 400 colonies per plate are most reliable. For ordinary work 3, and for accurate work 5 to 10 platings from a single sample are recommended. F. W. TANNER.

Neutralizing acid mine waters. ANON. *Eng. Mining J.* 107, 478(1919).—The advantages of the use of MgO in preference to CaO and  $\text{Na}_2\text{CO}_3$  are discussed. Only 20 parts of MgO are required as against 28 parts of CaO and 53 parts of  $\text{Na}_2\text{CO}_3$ . The  $\text{MgSO}_4$  formed is much more sol. than  $\text{CaSO}_4$ . MgO is insol. in neutral water, while much  $\text{Na}_2\text{CO}_3$  is wasted owing to its high soly. MgO is obtainable free from org. impurities which interfere with certain metallurgical processes. W. G. KOUPAL.

Remarks on active carbonic acid in connection with water supply. J. A. HEIJMANN. Heemstede. *Chem. Weekblad* 16, 105-20(1919).—A general discussion. It deals chiefly with the influence of plant and animal organisms, mostly algae and bacteria, on the amt. of free  $\text{CO}_2$  occurring in public water supplies. The conclusion is that algae should not be excluded from sand filters, because their usefulness in assimilating free  $\text{CO}_2$  outweighs any harm they may cause. JULIAN F. SMITH.

Baryta as substitute for soda in water purification. F. HUNDESHAGEN. *Z. offentl. Chem.* 24, 159-67(1918); *J. Soc. Chem. Ind.* 37, 670A.—In the softening of boiler water contg.  $\text{CaSO}_4$ , the use of  $\text{BaCl}_2$  results in the pptn. of  $\text{BaSO}_4$ , which does not form a crust to corrode the boiler. If  $\text{BaCO}_3$  is used,  $\text{CaSO}_4$  is converted into  $\text{BaSO}_4$  and  $\text{CaCO}_3$ . The process leads to some loss of  $\text{BaCO}_3$ , which is used in excess, but if the precipitant is added to the hot water, only 5-10% in excess need be used and the pptn. of Ca is complete.  $\text{Ba(OH)}_2$  reacts with  $\text{CaSO}_4$  to form  $\text{BaSO}_4$  and  $\text{Ca(OH)}_2$ . The latter is objectionable on account of its tendency to form a hard crust on the hottest parts of the boiler. In the presence of  $\text{Ca(HCO}_3)_2$ ,  $\text{BaSO}_4$  and  $\text{CaCO}_3$  are pptd. If the  $\text{CaSO}_4$  is in excess, a little  $\text{Ca(OH)}_2$  is formed, but this can be removed with  $\text{BaCO}_3$  or with  $\text{Na}_2\text{CO}_3$ . Baryta water ppts.  $\text{Mg(OH)}_2$  from Mg salts. Ba aluminate acts as a ppt. in a similar manner to  $\text{Ba(OH)}_2$ . Formulas and examples are given for calcg. the amt. of precipitant to be used for various combinations of hardening salts. E. H.

Baryta as substitute for soda in water purification. F. HUNDESHAGEN. *Z. offentl. Chem.* 24, 175-86(1918); *J. Soc. Chem. Ind.* 37, 713A; cf. preceding abstr.—H. gives examples of the cost of treatment by the baryta process for various combinations of hardening salts, as well as directions for the chem. control of the process in practice. E. H.

**Deoxidizing water to prevent pipe corrosion.** F. N. SPELLER. *Eng. Mining J.* 107, 480.—Reports are given of tests of corrosion by deoxidized water used for heating purposes. After 13 months' service wrought iron and steel plates were uncorroded. Zn and brass plates showed no pitting while the loss as a brass-steel union was 16% as against total corrosion in raw water. Speller's deoxidizer does not completely remove the  $O_2$  but considerable amts. of  $H_2$  are found between which and the  $O_2$  a proportionate ratio seems to exist which inhibits corrosion.

W. G. KOUPAL.

**Chloramine tried by New York City.** FRANK E. HALE. *Eng. News-Record* 82, 556(1919).—Treatment of Espous Creek with  $CaOCl_2$  in amts. 0.4 p. p. m. available. Cl killed trout. Mixt. of  $NH_4OH$  and  $CaOCl_2$  were tried but found that cost per unit of available Cl for chloramine was double that of hypochlorite alone. Small amts. of Cl may be effective in waters of low mineral and org. content. A given quantity of Cl in a water did the same work in the elimination of bacteria, winter or summer, regardless of temp.

FRANK BACHMANN.

**Chlorine absorption and the chlorination of water.** ABEL WOLMAN AND LINN H. ENSLOW. *J. Ind. Eng. Chem.* 11, 209-13(1919).—The significance of Cl absorption and efficient dosage in relation to the rate of absorption as effected by color, turbidity and oxygen consumed is discussed. Color readings cannot be adapted to the prediction of Cl absorption readings. Turbidity readings are not a safe index of Cl absorption for different supplies but may be adapted to individual supplies. Oxygen consumed values correlate and are independent of the source or nature of the water. The selection of an effective Cl index is discussed.

E. P. FAGER.

**Sulfur of the waters of Barèges.** J. DUFRENOY. *Compt. rend. soc. biol.* 81, 1238 (1918).—S. is one of the principal constituents of the waters of Barèges to which may be attributed the beneficial effects of sterilization and cicatrization of wounds bathed therein. The sulfides present in soln. in these thermal waters are oxidized on contact with air with production of crystd. S; this oxidation is principally due to the action of certain microorganisms. The cryst. forms of S produced were as follows, each form being constantly associated with certain microorganisms: (1) elongated needles (in the presence of colonies of leuconostoc); large, isolated, dissymmetric hexagonal tablets (in the presence of bacteria); very small octahedra and dissymmetric hexagonal tablets (in the presence of bacteria); very small octahedra and dissymmetric forms derived from octahedra (in presence of certain bacteria). All of the crystals belonged to the orthorhombic system, but presented the minor variations noted above.

H. S. PAINE.

**Rotary screens remove dirt from water at St. Paul, Minn.** ANON. *Eng. News-Record* 82, 566-7(1919).—Two motor-driven rotary screens of the drum or cylindrical type remove vegetation and solid particles from drinking water. Engineering details of designs are given.

FRANK BACHMANN.

**Significance of black sands in filters.** J. E. WELKER AND C. C. YOUNG. *J. Am. Water Works Assoc.* 5, 425-8(1918); *Can. Eng.* 35, 550.—Manganese and iron were responsible for the color. The darkening ultimately results in a decrease of filter efficiency. Carelessness and delay in washing are considered responsible.

D. K. FRENCH.

**Water pollution and fish life.** VICTOR E. SHELFORD. *J. Am. Water Works Assoc.* 5, 437-7(1918); cf. *C. A.* 12, 1224.—Pollution of water with manufacturing wastes and sewage not only decreases our fish resources but prevents their easy recovery. Investigation as to the relative toxicity of these wastes to fish in various stages of growth, the nature of the polluting substances and their removal is urged.

D. K. FRENCH.

**Water treatment at Council Grove, Kansas.** LOUIS L. TRIBUS. *J. Am. Water Works Assoc.* 5, 438-47(1918).—Alum is used as a coagulant; but instead of being all

added at one time, four applications of the necessary quantity are made at various points in the plants operation, with very satisfactory results. Prior to this method of introduction of alum, the coagulant seemed ineffective. D. K. FRENCH.

Property of certain waters with reference to their action on metals. S. W. PARR. *J. Am. Water Works Assoc.* 5, 451-3(1918).—Certain waters in Illinois running high in carbonates and bicarbonates have shown a tendency, under boiler conditions, to produce the caustic radical which decomposes  $\text{NH}_4$  salts when present, thus introducing a corrosive gas to the steam generated, which has been found to affect brass parts of certain heating systems. The trouble seemed greatest from the returns which were highly ammoniacal. D. K. FRENCH.

The deoxygenating effect of the effluent from the Miles acid process of sewage treatment. F. W. MOHLMAN. *J. Ind. Eng. Chem.* 11, 325-7(1919); cf. *C. A.* 12, 2102.—Expts. were made to det. the extent to which the dissolved O in sea water from New Haven harbor would be used up by the unoxidized  $\text{SO}_2$  in the Miles acid effluent. An effluent containing 200 p. p. m. of  $\text{SO}_2$  will reduce all of the O in 5 to 7 vols. of sea water, the O being absorbed immediately. This may cause a distinct zone of deaerated water at the outfall of the effluent. The  $\text{SO}_2$  may be oxidized by aeration before diln., the amt. of air required being much smaller than that required for the activated sludge process. The aerated effluent will not deaerate large vols. of the dilg. water. Results of expts. are shown by tables. E. P. FAGER.

The sewage disposal problem in Chicago. C. D. HILL. *Am. J. Pub. Health* 8, 833-7(1918).—A review of the method of sewage disposal for the city of Chicago is given. At the present time the rate of diln. allowed is insufficient and it will be necessary to increase the flow or, if the Federal Government should not permit the necessary diln., to install a sewage purification plant. M. C. PERRY.

Dissolved oxygen as an index of the pollution of New York Harbor. KENNETH ALLEN. *Am. J. Pub. Health* 8, 838-42(1918); *Eng. Contr.* 51, 33(1919); *Can. Eng.* 35, 531(1918).—The results of the analysis of 4,201 samples show that: there is no danger of the development of putrefactive conditions in any of the main bodies of water in N. Y. Harbor during the cold months of the year; in East River and in Harlem River there is one-half as much dissolved O in summer as in 1909, and in the rest of the harbor about three-fourths as much as in that year; the conditions in Lower East and Harlem Rivers are such that local nuisances may be looked for after several days of hot weather; the conditions of certain parts of the Hudson River and of the Upper East River are approaching those which already exist in the Lower East River.

M. C. PERRY.

Steffens-house waste water and stream pollution. WALDO S. COULTER. *Sugar* 21, 142(1919).—The present method of disposal, settling in ponds, is a public nuisance. Good results are obtained by filtering the waste waters through a fine-mesh screen, cleaned by a jet of compressed air. The screenings obtained contain little moisture and may be dried in open heaps without creating offensive odors, and sold as fertilizer. The screened liquid is filtered through sand or similar filter, and can then be directly discharged into streams. The activated sludge method of disposal may also be used, but is not so advantageous because of the short duration of the best campaign.

F. W. ZERBAN.

Poisons in sewage. G. ROMIJN. *Water, Bodem, Lucht* 1918, 78-84, 99-112; *Chem. Weekblad* 16, 83-4.—Various fishes, Crustaceae, etc., were tested with poisons likely to occur in sewage. Their sensitivity, especially to  $\text{PhNH}_2$  and its derivs., differed greatly from that of man. Many additional species of aquatic animals must

be tested before reliable conclusions can be drawn. Regulations governing sewage contamination should not be established without careful preliminary investigation.

JULIAN F. SMITH.

**Studies on the treatment and disposal of industrial wastes. I. The treatment and disposal of strawboard waste.** HARRY B. HOMMON. U. S. Public Health Serv., *Public Health Bull.* 97, 5-70(1918).—From data obtained with an exptl. plant at a small strawboard mill the following plan for the disposal of fluid waste is recommended: The waste is sedimented in large tanks for about 2 hrs., during which 50% of the suspended matter is removed. The settled waste is then removed to filters with screened cinders as the filtering medium. These filters removed most of the remaining material and practically all the carbonate alkalinity. The filtered  $H_2O$  is so purified that when dild. 1:1 with pure  $H_2O$  it will not kill fish living in it. The sludge removed twice a mo. from the sedimenting tanks and filters was dried in open beds over a layer of cinders or straw. It seems possible that the dried sludge can be used as fertilizer.

**II. The determination of the biochemical oxygen demand of industrial wastes and sewage.** EMERY J. THERIAULT AND HARRY B. HOMMON. *Ibid* 71-86.—An intensive study of the excess O method for detg. the biochem. O demand of liquid wastes was made and the method so modified as to give consistent and accurate results with sewage, strawboard mill wastes, and a variety of other industrial wastes. The summary of the results of a large no. of routine detns. of the biochem. O demand of strawboard and tannery wastes is presented. It is shown that the precision of the values obtained with different concns. is within 5% if the dilg.  $H_2O$  has an O demand of less than 0.6 p. p. m. at 20° for 10 days and the temp. and O content of the  $H_2O$  are adjusted to the incubation temp. By using  $H_2O$  with a very low O demand and adjusting its temp. and O content before making the dilns., the results are perfectly reliable if the depletions are within 20 to 90% of the initial O content. The technic of the method is also simplified considerably since fewer concns. need be put up and the same concn. can be used to derive values over different periods of time.

**Water-softening material.** G. H. WIDNER. U. S. 1,294,007, Feb. 11. The pat. relates to the prepn. of a base-exchanging water-softening material by levigation of clays and treatment of them with NaCl, followed by drying and baking at a temp. of 600-700° to render the material resistant to the powdering action of the water. Impurities such as Ca and Mg compds. are removed by the washing to which the clay is subjected in the preliminary treatment.

**Composition for removing and preventing formation of scale steam-boilers.** E. R. WILLIAMS. U. S. 1,294,738, Feb. 18. A boiler compd. is prepd. by mixing tannin 4-6, and graphite 1-2, with molten NaOH 145 parts.

**Removing scale from boilers.** T. WAKEFIELD. U. S. 1,293,585, Feb. 4. A soln. for removing scale from boilers is formed of  $Na_2CO_3$  5 lbs., urine 8 oz. and  $H_2O$  1 gal.

## 15. SOILS, FERTILIZERS AND AGRICULTURAL POISONS.

J. J. SKINNER.

Tests of the influence which the microorganisms carried to the soil in sewage can have on its fertilizing power. GIULIO MASONI. R. università di Pisa, istituto di chimica agraria, *Studi e ricerche* No. 22, 295-327.—Tests were made with sewage to see if by partial sterilization and by sterilization carried to the extreme limit compatible with agr. expts. vegetation is affected differently than by supplying the sewage in its natural state. Pots were employed containing 12 kg. of ordinary earth in which for the first series of expts. buckwheat was grown and for the second series buckwheat, corn and Dolichos. The order of the expts. was pots (1) without the addition of sewage, (2) with sewage in the natural state, (3) with sewage sterilized by means of heat (boiling), (4) with sewage partially sterilized with  $H_2SO_4$  added to the extent of 1% by wt., (5) with sewage in the natural state with the addition of  $Na_2SO_4$  in quantity corresponding to the quantity of  $SO_4$  which was added with 1% of  $H_2SO_4$ . In order better to ascertain the action of the microorganisms in the sewage a second group of expts. was made using earth completely sterilized by heating to 130-140° for 8 hrs. The order of these was pots (1) with sterilized earth without the addition of sewage, (2) with sterilized earth and sewage in the natural state, (3) with sterilized earth and sewage sterilized by heat. The moisture content of these was brought to that of the preceding group of expts. by the addition of distilled  $H_2O$ . In the first series of expts. the sewage was spread on the earth; in the second it was mixed with it. With earth in the natural state sewage sterilized by boiling gave much higher yields than the untreated sewage; sewage treated with  $H_2SO_4$  gave results equal to those obtained with boiled sewage and sewage treated with  $Na_2SO_4$  gave yields better than natural sewage but slightly inferior to that with sewage treated by boiling or with  $H_2SO_4$ . With earth sterilized at 130-140° natural sewage gave yields greater than those obtained without sewage or with sterilized sewage. Comparing the results of the expts. with natural earth and sterilized earth the yield of the check pots was slightly greater for buckwheat and more so for corn in the sterilized than the natural soil. Pots with natural sewage gave nearly the same yield of buckwheat for the two soils; on the contrary, the sterilized earth gave considerably greater yields of corn. Pots with boiled sewage always gave inferior yields in the sterilized soil to those in the natural soil. ALBERT R. MERZ.

Influence of salts on the nitric-nitrogen accumulation in the soil. J. E. GRAVES, E. G. CARTER AND H. C. GOLDTHORPE. Utah Agr. Expt. Sta. *J. Agr. Research* 16, 107-35(1919); cf. *C. A.* 11, 378.—Samples of soil were treated with varying amts. of the chlorides, nitrates, sulfates, and carbonates of Na, K, Ca, Mg, Mn and Fe, and after the addition of dried blood the mixt. was incubated for 21 days at 28-30°. At the end of the period the change in  $NO_3$  was detd. The results are tabulated and shown graphically. Toxicity was generally caused by the salt as a whole and not by the negative ion, and with a few exceptions all the salts were toxic toward nitrification at a lower concn. than was the case for ammonification as reported in a previous paper. With the different salts the rise in toxicity was by no means with, and was not controlled by, the osmotic pressure. Salts which proved to be very toxic to nitrifying organisms were:  $CaCl_2$ ,  $Na_2SO_4$ ,  $Na_2CO_3$  and  $Ca(NO_3)_2$ . With the exception of  $Na_2SO_4$ ,  $Na_2CO_3$ ,  $CaCO_3$ ,  $K_2SO_4$ ,  $K_2CO_3$  and  $Fe(NO_3)_3$  all salts stimulated nitrification at some concn. The most effective were  $CaCl_2$  and  $CaSO_4$ , which increased nitrification 67% and 97%, resp. Compds. which increased  $NO_3$  production were also good plant stimulants. Several of the nitrates were found to cause large losses in  $NO_3$ , and expts. were conducted which showed this to be due, not to denitrification but to change of the N into some other form, probably protein. R. N. HARGER.

**Cultural experiments on moor lands.** H. VON FEILITZEN. *Svenska Mosekulturför. Tidskr.* 31, 16-42, 129-69(1917).—The expts. described in this report were carried out in 1915 by the Swedish Moor Culture Association at Flahult and Torestorp in Jönköping. An increase in yield of hay in a 5-year test was secured by mixing sand with the surface layer of an imperfectly decomposed peat soil. The application of the sand paid for itself with the 3rd cutting. Shallow bog soils when mixed or covered with sand also gave favorable results in the growth of different crops as compared with the untreated soils. With some crops the sand-covered plats gave best results, and the sand-mixed plats with others. Owing to the high N content of the moor soils the use of nitrogenous fertilizers on these soils was in general without result. Of the 3 P carriers, Thomas slag gave the best result, with superphosphate second and bone meal third. Early seeding as compared with late seeding gave better returns with such crops as turnips, oats, barley and potatoes. Leguminous crops grown for green fodder were not influenced much by late seeding. Results are given of variety tests made on peat soils with such crops as oats, barley, field peas, potatoes, turnips, carrots and different grass mixts.

W. H. ROSS.

**New process for the cultivation of the cereals.** CARLO ROSSI. Legnano. 8 pp. ULRICO HOEPLI. Milan, 1917.—The new process consists in the immersion of the seed for 12-14 hrs. in a 3% soln. of  $\text{NH}_4\text{NO}_3$ , 50 kg. of seed requiring 100 l. of this soln. The seed are then withdrawn, dried in the air and sown in the customary way. Seed thus treated and cultivated in soils fertilized in the ordinary manner with superphosphate and nitrate gave a 25% greater yield of wheat or corn and 30% more straw. In all the tests the treated grain appeared 3 to 4 days before the non-treated grain and maintained a distinct superiority during the entire vegetative period, though there was sometimes observed with the treated grain a tardiness in maturation. The treated grain was also much more resistant to lodging. An exact detn. of the N absorbed by the wheat seed caused a belief that this was greater than that which the plant grown from seed which had not been treated was able to absorb during its entire vegetative period from the soil fertilized with  $\text{NaNO}_3$ . Tests conducted with all precautions confirmed this and "it can be affirmed that the new system of the . . . . fertilization of seed can be substituted for the old process of fertilization of the soil and a greater production gotten than that obtained with the processes of soil fertilization." Instead of the 200 kg. of  $\text{NaNO}_3$  per hectare required in the present methods of fertilization but 6 kg. of  $\text{NH}_4\text{NO}_3$  are needed.

ALBERT R. MERZ.

**Comparative test of several nitrogenous fertilizers.** BACHELIER. *Compt. rend. acad. agr. France* 5, 168-70(1919).—Field expts. were made to compare the fertilizing value of  $\text{NH}_4\text{NO}_3$  with that of other N-containing salts as was previously done in the pot expts. of Schloesing (*C. A.* 12, 1582). Beets were used as the crop.  $(\text{NH}_4)_2\text{SO}_4$  gave better results in all cases while  $\text{NaNO}_3$  gave a larger yield when 0.600 kg. N was applied per acre and a smaller yield when 0.900 kg. per acre was used. The tests seem to confirm that the unit of N in  $\text{NH}_4\text{NO}_3$  has essentially the same value as in the other salts hitherto furnished to the trade. The beets fertilized with  $\text{NaNO}_3$ , however, were strongly attacked by the disease, "du coeur de la betterave," due to *Phoma betae* which gives a yellow color to the leaves, while those fertilized with  $\text{NH}_4\text{NO}_3$  did not suffer thus.  $\text{NH}_4\text{NO}_3$  can apparently be as easily spread as  $\text{NaNO}_3$ . ALBERT R. MERZ.

**The mineral superphosphate industry.** E. STAUB. *Chimie & industrie* 2, 123-32 (1919).—A review is given of the process used in the manuf. of superphosphate, and also of the various other processes that have been proposed for treating phosphate rock, such as (1) digestion with  $\text{NaHSO}_4$ ; (2) ignition with silica and an alkali or alk.-earth salt to form the so-called artificial slags; (3) ignition at 600-800° with equal parts of  $\text{Na}_2\text{CO}_3$ ,  $\text{CaCO}_3$  and  $\text{Na}_2\text{SO}_4$  for the prepn. of a product known as "tetraphosphate;"

and (4) digestion with  $H_2PO_4$ , obtained either by the  $H_2SO_4$  or the volatilization method, for the prepn. of double superphosphate.

W. H. ROSS.

A new phosphatic fertilizer, "tetraphosphate of lime." E. MIEGE. *Compt. rend. acad. agr.* 4, 90-7(1918).—"Tetra" was invented in 1911 by Stoppani and introduced into commerce in 1914. Up to the present its use has been restricted to Italy. It is produced by heating for several hrs. at about  $600^\circ$  a powdered mixt. of natural mineral phosphates and 6% of a reagent composed of equal parts of Na, Mg and Ca carbonates and  $Na_2SO_4$ . This is followed by cooling and quick hydration of the mass and finally mixt. with cheap inert substances in order to bring the content of  $P_2O_5$  to that of commercial superphosphates. Its use has had a remarkable development due to the satisfactory results of numerous agricultural tests. It has the advantages of not possessing causticity or acidity and consequently is not harmful to vegetation and to sacks. It does not undergo reversion; its manuf. is simple and not costly and permits of the use of low-grade natural phosphates; its reaction is very slightly alk.; the cost and selling price are lower than those of superphosphates. It has, however, in spite of its commercial name, its  $P_2O_5$  entirely in the form of  $Ca_3(PO_4)_2$ , which is almost impossible of being practically distinguished from natural phosphates and does not possess a soly. in the usual solvents exceeding these. Thus:

|                                           | Tetra. | Tetra. | Tetra. | Phosphorite. | Phosphorite. |
|-------------------------------------------|--------|--------|--------|--------------|--------------|
| % of total $P_2O_5$ .....                 | 18.85  | 19.45  | 17.30  | 15.72        | 26.50        |
| % $P_2O_5$ sol. in ammoniacal citrate.... | 0.83   | 1.00   | ...    | ...          | ...          |
| % $P_2O_5$ sol. in 2% citric acid.....    | 6.80   | 6.55   | 7.50   | 6.65         | 10.65        |
| % $P_2O_5$ sol. in $CO_2$ .....           | 8.00   | 8.40   | 7.10   | 10.00        | 5.85         |

It has been shown, however, that assimilability and soly. are not always strictly correlated and bone phosphates, guanos and bone blacks, etc., furnish at times crop yields exceeding those which more sol. fertilizers can give. Petermann and Graftian on the other hand have found that the fertilizing power of certain phosphatic slags is inversely proportional to their soly. A résumé is given of the results obtained with the use of "tetra" in expts. carried out in Italy and France. These on the whole are favorable. The scientific explanation of this efficacy of "tetra" has not yet been found.

ALBERT R. MERZ.

A new fertilizer, the tetraphosphate of lime. A.-CH. GIRARD. *Compt. rend. acad. agr. France* 4, 69-74(1918).—Announcement, résumé and discussion of the paper by Miège (cf. preceding abstract). The name is a misnomer as the  $P_2O_5$  is in the state of  $Ca_3(PO_4)_2$ . G. and Müntz long since showed that the degree of fineness and aggregation of the phosphate is one of the principal factors of the rapidity of attack of various solvents on it. The suggestion is made that in future expts. not only should "tetraphosphate" be compared with superphosphates but also with the natural phosphate. The process of its manufacture by reason of its economy of installation and simplicity of operation should be within the reach of agricultural associations and besides should permit of the utilization of numerous phosphatic deposits in France which have been abandoned because they furnish minerals too poor for conversion into superphosphates.

ALBERT R. MERZ.

The detection of the adulterants in bone superphosphates. GIULIO MASONI. R. università di Pisa, istituto di chimica agraria, *Studi e ricerche*, No. 22, 139-70.—The procedure is begun with the following preliminary tests. A little of the substance to be tested is cautiously heated in a porcelain dish until charred and then calcined with the blast lamp in a Pt dish frequently removed from the flame. A pure bone phosphate does not give any evolution of white fumes. After long calcination the dish is removed from the flame and the substance observed while the dish is still incandescent. A pure

bone phosphate should not give an intense yellow color but should remain whitish or at most very pale yellow. The residue of such calcination, cooled, should keep its white color, or should have a pale reddish tint only after the most prolonged heating. It should be almost completely sol. in hot 10% HCl or, if there be the slightest residue, the liquid should be perfectly clear after a short settling. Then the moisture, the total  $P_2O_5$ , the  $P_2O_5$  sol. in  $H_2O$  and citrate, the total  $SO_3$ , and the residue insol. in a mixt. of 20 cc. HCl + 5 cc.  $HNO_3$  + 65 cc.  $H_2O$  (using 5 g. sample of the superphosphate) are detd. Reporting the analytical results on the dry basis (100°), the following values are established, total  $SO_3$ /total  $P_2O_5 \times 100$  and total  $SO_3$ /sol.  $P_2O_5 \times 100$ , denoted as *ST* and *SS*, resp. These should not in a good bone superphosphate exceed 130 and the difference,  $SS - ST$ , should not be notable. The insol. residue of a bone superphosphate should not exceed 1.30%. Values of *SS* and *ST* much below 110 should cause a suspicion of the addition of pptd. phosphate. If the aq. soln. gives a notable reaction for Cl, pptd. phosphate is indicated. C particles detected by means of a magnifying lens in the  $H_2O$ -insol. residue indicate ashes. Effervescence with acid indicates calcareous substances such as powdered oyster shells, etc. In special cases it may be necessary to det. pyrophosphoric acid; if this is present in considerable quantity pyrophosphates or "superphosphates from pyrophosphates" are indicated. The individual adulterants are considered as follows: (1) Mineral superphosphates, in the sense that the adulteration can be made either directly with mineral superphosphate or by means of the addition of mineral phosphates to the powdered bone. The values *ST* and *SS* are higher than 130 (and the difference,  $SS - ST$ , in not a few cases may be large) and the insol. residue is notably higher than the greatest found in bone superphosphates. (2) Superphosphates of bone ash; in the same sense as before. The same criteria hold as for mineral superphosphates. (3) Superphosphates of bone black; same as (1) and (2). (4) Gypsum, added as customarily in the "mixing" or mixed directly with the superphosphate. The 2 values *ST* and *SS* are increased, the difference  $SS - ST$  is most sensitive to the possible reversion to which the gypsum can easily give rise and the insol. residue is raised. (5) Sand. Even a considerable addition while causing a diminution in the relative quantities of  $P_2O_5$  and of  $SO_3$  should not cause the values *ST* and *SS* to vary greatly but an addition, though slight, should be easily discovered by the quantity of insol. residue. (6) Calcareous substances (oyster shells and the like). If added before "working" the values *ST* and *SS* should increase while if added afterwards there should be more or less considerable effervescence on treatment of the substance with mineral acids and there may be also a certain reversion by which the difference  $SS - ST$  will be increased. In all cases the quantity of insol. residue will increase. (7) Ashes. If added during the "mixing" the values *ST* and *SS* should increase. Added afterwards they can give an effervescence on addition of mineral acids and, causing a reversion, make the difference  $SS - ST$  large. They do not make the insol. residue increase greatly but the non-calcined insol. residue shows more or less minute particles of C. (8) Superphosphates of phosphatic guanos. The addition of such superphosphates causes a change in the two values *ST* and *SS* and increases the quantity of insol. residue. (9) Pptd. phosphates. These tend to decrease the values *ST* and *SS* as well as the quantity of insol. residue. They also give an intense reaction for chlorides in aq. solns. of the substance. (10) Pyrophosphate of Ca. This product is obtained by heating mineral phosphate with  $SO_2$  in contact with air (A. Menozzi, *Agricoltura moderna* 15, 716(1909)). In the product thus obtained the  $P_2O_5$  is almost entirely insol. in  $H_2O$  and in neutral ammonium citrate; also the  $P_2O_5$  sol. in dil. citric acid is very small and not much greater than that of the phosphate before the treatment. Addition of this causes the superphosphate to contain a quantity of  $SO_3$  much less than that of an unadulterated superphosphate and causes a great difference

between the total and sol.  $P_2O_5$  as well as a large jump in the difference between *ST* and *SS*. Besides this the insol. residue is greatly increased. In doubtful cases the pyrophosphate of Ca should be detd.; it should be high, for a little pyrophosphate of Ca may be formed in the manuf. of superphosphate during the artificial drying process. (11) Simple bone meal and mineral phosphates. Added intentionally or present in the superphosphate because of insufficient action of the  $H_2SO_4$  these substances tend to lower the value *ST*. They should be detected easily by the great difference between the total  $P_2O_5$  and the sol.  $P_2O_5$  and the by difference between *SS* and *ST*. (12) Various nitrogenous substances. The method does not lend itself to detecting them directly.

ALBERT R. MERZ.

The use of ammonium citrate in the determination of phosphoric acid. A. QUARTAROLI AND A. ROGAI. R. università di pisa, istituto di chimica agraria, *Studi e ricerche* 22, 427-43.—The present official Italian method for the analysis of superphosphates is based on the use of  $NH_4$  citrate and is in substance that proposed by Appiani (*Stas. sper. agr. ital.* 28, 817(1893)). Studies carried out by Q. (C. A. 9, 31) caused the belief that there were sources of error which had not been considered nor even suspected in the analysis of Thomas slag and of mineral superphosphates, exceptionally rich in Al by this method. Beside the fact that Al and Fe in large quantity can limit and even prevent the pptn. of  $NH_4MgPO_4$  it has been observed that Mg if in sufficient excess can ppt. Fe and Al together with a variable quantity of org. matter. A series of expts. was conducted to ascertain at what concns. of  $NH_4$  citrate, of ferrous and ferric salts, of magnesia mixt., etc., the abnormal ppts. of basic salts or of Mg ferrite occur. Use was made of cupferron to det. the small quantities of Fe in the presence of a large excess of  $P_2O_5$  and Mg, as neither these nor Al had any influence on the pptn. of Fe from the HCl soln. of the ppt. obtained by means of magnesia mixt. Samples of Thomas slag were also examd. with reference to the compn. of the ppt. obtained. After soln. of the ignited ppt. in HCl, the Fe was removed with cupferron, the pyrophosphate was transformed to ordinary phosphate by boiling and the  $P_2O_5$  repptd. It is concluded from these expts. that (1) the citrate method for the analysis of slags can give rise in certain cases to serious errors, although there are 2 causes of error which in many cases tend to balance each other, pptn. of ferrites or citro-ferrites of Mg and the incomplete pptn. of  $P_2O_5$ . If the results are discordant, if the ppts. are not perfectly white, or if, heated, they have an abnormal aspect, the detn. of Fe can be made in the way indicated and the causes of error verified. In such case the elimination of Fe by means of cupferron previous to the pptn. should yield reliable results. Such procedure, however, is not in general practicable at present in com. analyses by reason of the greater complexity of the method and expenditure of time as well as because of the very high price of the cupferron. (2) In the rarer cases where it is a question of Fe or Al phosphates the citric method is inapplicable and the principle of the pptn. at all and at any concn. of  $P_2O_5$  in the presence of Fe or Al, preventing the pptn. of these metals with citric acid, can give rise to large errors. (3) The existence of the phenomena studied does not compromise the present method of the analysis of superphosphates except in some exceptional cases of superphosphates rich in Al. The choice of the concn. and of the quantity of the solns. to be used according to the official Italian method has been very fortunate, since with varying amts. of  $NH_4$  citrate and of magnesia mixt. most serious difficulties might be encountered. "Only we believe it useful, considering the influence that the concn. of the soln. of Mg has on the formation of abnormal ppts., to fix with greater exactness the compn. of it."

ALBERT R. MERZ.

The action of manganese dioxide on nitrogenous organic substances, especially amides, with regard to the use of the dioxide as a fertilizer. GIOVANNI LEONCINI AND COSIMO PIERI. R. università di Pisa, istituto di chimica agraria, *Studi e ricerche*,

22, 328-48.—A series of expts. was carried out to ascertain with what ease  $MnO_2$  oxidizes nitrogenous org. substances with the ultimate view of establishing whether oxidation may be one among the numerous actions which Mn can exert in the soil for the benefit of vegetation. Only  $NH_3$  and  $N_2O_5$  were sought after among the products of such oxidation. No  $HNO_3$  was formed by boiling 100 cc. of a 2% soln. of  $(NH_4)_2SO_4$  for 5 hrs. with 5 g. of  $MnO_2$ . Slight acidity or alkalinity had no effect. Similarly no  $HNO_3$  was obtained with a 2% soln. of  $(NH_4)_2CO_3$ . Mixts. containing 2% solns. of  $(NH_4)_2CO_3$  with variable quantities of  $MnO_2$  maintained at  $30^\circ$  in a thermostat for a varying number of days yielded no  $HNO_3$ .  $NH_4OH$  was quickly attacked while  $(CH_3)_2N$  did not show the least sign of attack by  $MnO_2$ . A very dil. soln. of egg albumin gave no sign of oxidation on boiling; a similar soln. of legumin gave a very feeble reaction for nitrate after 6 hrs. which was not, however, to be regarded as a product of the oxidation of the protein itself. In acid and in alk. solns. there was no such indication of oxidation. In neutral 2% soln. urea gave a very strong reaction for  $NH_3$  after 4 hrs. boiling with  $MnO_2$  and a very marked reaction for  $HNO_3$  after 9 hrs. In acid soln. the quantity of  $NH_3$  formed was less and the  $HNO_3$  was more quickly formed while in alk. soln. there was a rapid formation of  $NH_3$  and a slight reaction for  $HNO_3$ . The formation of  $NH_3$  was probably due to hydrolysis and not to the  $MnO_2$ . A neutral soln. of urea kept 5 days at  $30^\circ$  gave no trace of  $HNO_3$  and but insignificant quantities of  $NH_3$ . After 5 hrs. boiling of a neutral soln. of acetamide appreciable quantities of  $HNO_3$  were obtained with only traces of  $NH_3$ . Glycine and hippuric acid gave no  $HNO_3$  and only traces of  $NH_3$  in neutral, acid and alk. solns. Similarly alanine was not oxidized nor were leucine or aspartic acid. The last two compds. gave a slow formation of  $NH_3$  while alanine gave no trace of  $NH_3$ . Taurine, tyrosine and benzamide gave no reaction with  $MnO_2$ . Uric acid gave no  $HNO_3$  either at  $30^\circ$  or on boiling. A small quantity of  $NH_3$  only was formed. Xanthine and hypoxanthine, whether in neutral, acid, or alk. soln. at  $30^\circ$  or at boiling temp., gave no  $HNO_3$ . A very small amt. of  $NH_3$  was formed at  $30^\circ$  and this formation was more rapid at the higher temp. A 3% soln. of cyanamide was boiled with  $MnO_2$  with the results given in the following table:

|                                       |      |      |      |      |      |      |
|---------------------------------------|------|------|------|------|------|------|
| Hrs. of boiling.....                  | 10   | 20   | 25   | 30   | 35   | 40   |
| G. $HNO_3$ per 1000 cc. soln. present | 0.53 | 1.46 | 1.08 | 0.88 | 0.82 | 0.74 |

A 0.1% soln. of dicyanodiamide gave on boiling the following:

|                                |      |      |      |      |      |
|--------------------------------|------|------|------|------|------|
| Hrs. of boiling.....           | 2    | 4    | 6    | 8    | 10   |
| G. $HNO_3$ per 1000 cc. soln.. | 0.37 | 0.49 | 0.61 | 0.99 | 0.99 |

A 0.1% soln. of sodium cyanamide gave after an hour's boiling 0.14 g.  $HNO_3$ ; after 4 hrs., 0.45 g. The soln. also gave an abundant formation of  $NH_3$ . At  $30^\circ$  cyanamide gave neither  $NH_3$  nor  $HNO_3$ ; dicyanodiamide formed no  $NH_3$  at all but gave very small amts. of  $HNO_3$  (0.01 g. per 1000 cc. after 12 and 19 days, 0.07 g. after 26 days and a trace at end of 34 days). It is concluded that in nearly all the compds. examd. the union of the N with the remainder of the mol. is so close as to render the mol., the compds. being in aq. soln., almost absolutely refractory to the oxidizing action of  $MnO_2$  whether at a relatively low temp. ( $30^\circ$ ) or at the boiling temp., at least with respect to transforming org. N into nitric N. Exceptions to this were the amides of the acids and some polymers of these (dicyanodiamide), in which the union between  $-NH_2$  and the acid radical is very weak. The  $MnO_2$  acts on such amides in aqueous solns. as a very energetic oxidizing agent transforming the amide N into nitric N. This, however, does not take place except at the boiling temp.; at  $30^\circ$  there is no oxidation into nitric N but only the formation of  $NH_3$ . Whence it results with almost absolute certainty that in spite of the small quantity of  $NH_3$  which is formed at  $30^\circ$  such substances placed in the ground (which hardly ever exceeds this temp.) cannot exert a direct oxidizing

action of any importance upon org. nitrogenous substances. It will perhaps exert a very useful action by giving rise, through special soil conditions, to a colloidal soln. of diastatic behavior aiding the activity of bacteria, specific agents of the various oxidations which occur in the soil, and more especially the work of the nitrifying bacteria.

ALBERT R. MERZ.

The physiological effects of ammonium salts on plants. H. G. SODERBAUM. *Kgl. Landbruks-Akad. Handl. Tid.* 57, 513(1918); cf. *C. A.* 12, 1230.—The trials for 1918 were continued with oats and barley in order to det. the limits of the harmful effects of  $\text{NH}_4$  salts on these cereals. The trials were extended so as to include rye grass and vetch. The trials were made in glass cylinders each containing 29 kg. sandy soil to which needed amts. of phosphates and potash were added. The  $(\text{NH}_4)_2\text{SO}_4$  was used with  $\text{NaNO}_3$ , each in varying amts., but in such quantities that 1 g. of N was added to each pot, corresponding to 200 kg. N per hektar. The limits of the harmful effects of  $(\text{NH}_4)_2\text{SO}_4$  on oats lies between 160 and 200 kg. N per hektar, and on barley the harmful effects appear slightly with 25 kg. and strongly with 50 kg. N per hektar. With rye grass no harmful effects were observed up to 200 kg. per hektar. With vetch the effect of  $(\text{NH}_4)_2\text{SO}_4$  was most pronounced; the smallest amts. used in any pot decreased the growth of plants. This plant was also sensitive to  $\text{NaNO}_3$ , but in less degree than to  $(\text{NH}_4)_2\text{SO}_4$ . Cf. *C. A.* 12, 1230.

C. O. SWANSON.

Rate of humification of green manure. R. H. CARR. *Proc. Ind. Acad. Sci.* 1916, 398-402; *Expt. Sta. Rec.* 39, 423-4(1918).—Data are presented on humus detns. and vegetation tests with corn, obtained in investigations already noted (*C. A.* 11, 2521), from which are drawn the following conclusions relative to the rate of humification of cowpeas, alfalfa, sweet clover, and oats used as green manures: Oats practically doubled the humus content of the soil, followed by sweet clover, cowpeas, and alfalfa in the order named; alfalfa failed to show any appreciable increase. All crops showed rapid humification, there being slight increase after 2 months. Rolling under the green manures proved to be better for corn than disking in or drying. The highest corn yield was obtained after oats, with alfalfa next. Additional data are presented showing the lime requirement (Veitch method) of the soils under the various treatments at time of application and at 2 and 6 months' intervals. Increased soil acidity was observed wherever the green manures were added, the acidity being less for the disked crops than for the undisked. Where the crops were dried before mixing with the soil no appreciable increase in acidity was noted. In all cases liming resulted in increased yields of corn.

E. H.

New deposits of guano in the Philippines. *Philippine Agr. Rev.* 10, 301(1917); *Bull. Agr. Intelligence* 9, 930.—In several instances, particularly in the southern provinces of the Island of Luzon, searches have resulted in the location of extensive guano deposits. This material, however, has invariably contained a low percentage of N, which condition was due no doubt to the extremely sol. substance contg. that element having leached away during the rainy seasons. Analysis of this material showed the following av. result: N 1,  $\text{P}_2\text{O}_5$  15 and potash 1%.

E. H.

Value of Philippine composts. F. B. SARAO. *Philippine Agr. and Forester* 6, 128-34(1918); *Expt. Sta. Rec.* 39, 523.—This reports the results of observations on the rate of decompn. and shrinkage, the percentage of moisture and total N, and the increase in total N in different materials composted in walled and unwallled and shaded and open piles. The materials studied included corn, cane, and sorghum trash; mixed herbaceous plants, including tomato and pea vines and amaranthus and other weeds; rice straw; cogon (*Imperata* sp.); bamboo leaves; and banana stems and leaves. The cane trash compost showed the highest percentage of N, 0.9%, that from corn trash and

mixed herbaceous plants being next in order with 0.84% each. Banana stems and leaves showed the highest shrinkage, and together with rice straw, composted most rapidly. Cogon showed the lowest shrinkage. No relation between the rate of decompn. and the percentage of N content in the compost was observed. E. H.

The potassium salts industry in war time (BRANET) 18. African oil-yielding plants (PIERREARTS) 27. Device for sampling (RILEY) 1. The phosphate production and resources of the world (MORGAN) 18. *Leucaena glauca* (ANON.) 12. The potassium problem and the utilization of olive-oil residue in Italy (L'ABATE) 18.

The American Fertilizer Hand Book. 12 Ann. Ed. Philadelphia: Ware Bros. Co., 1010 Arch St. \$1.50.

Fertilizer. P. M. SHUEY. U. S. 1,293,220, Feb. 4. Mineral or bone phosphate is mixed with about twice its weight of molten niter cake, and after mixing for 1-3 min. and while the mixt. is still fluid it is withdrawn from the mixing app. and allowed to set, cool and age. About 87% of the insol. Ca phosphate originally present in the mixt. is converted into mono- and di-Ca phosphates.

Fertilizer. P. H. CARTER. U. S. 1,293,029, Feb. 4. A fertilizer is formed of cyanamide, niter cake and "fertilizer stick" in substantially dry form. The cyanamide and niter cake are mixed first, to avoid loss of  $\text{NH}_3$  when the "stick" is added.

Fertilizer. G. J. FOWLER and G. MUMFORD. U. S. 1,294,080, Feb. 11. A bacterially active fertilizer in granular form is prepd. from sewage sludge.

Fertilizer. G. J. FOWLER. Can. 189,921, Apr. 29, 1919. A fertilizer consisting of bacterially active non-colloidal sewage sludge rich in N in a state available for plant food is made by forcing air through sewage in the presence of bacteria, thus forming an active sludge, which is heated to sterilize and dry it. It is then inoculated with a portion of fresh active sludge.

## 16. FERMENTED AND DISTILLED LIQUORS.

ROBERT WAHL.

Analysis of Portuguese Colares wines. J. V. GONCALVES DE SOUSA. *Revista Agronomica* 13, 90-3(1918); *Bull. Agr. Intelligence* 9, 1366-7.—To distinguish the Colares type of wine (1) G. analyzed 127 samples of red wine and 23 samples of white wine from these vineyards. Below are given the averages of several detns., the first figure for each value is for red wines, the second for white wines: Alc. by vol., 11.14%, 11.99%; by wt., 8.84%, 9.49%. Total dry ext. 23.41 g., 18.61 g. per l. Total acidity (expressed in  $\text{H}_2\text{SO}_4$  per l.) 4.65 g., 4.37 g. Fixed acidity (expressed in tartaric acid per l.) 5.96 g., 5.78 g. Volatile acidity (expressed in  $\text{AcOH}$  per l.) 0.95 g., 0.93 g. Ash (about 10% of the reduced dry ext.) red wine, 2.42 g. white wine 1.88 g. per l.  $\text{H}_3\text{PO}_4$  in the ash of red wine, 0.20 g., in that of white wine, 0.175 g. Reducing sugar 1.54 g., 0.99 g. per l. Glycerol 6.20 g., 6.59 g. per l. Tannin 0.81 g. per l.; 0.002 g. (it could be estd. in 3 samples only). Potassium bitartrate (by Berthelot and Fleuriu's method) 1.93 g., 0.75 g. per l. Two tables show the results obtained for each of the 150 samples of wine analyzed, and give the localities from which they came. E. H.

A new method for determining the watering of wine. I. J. PRATOLONGO. *Stas. sper. agrar. ital.* 51, 56-60(1918); *Bull. Agr. Intelligence* 9, 1104(1918).—The method reported by Pagnotta is based on the fact that natural wine forms a satd. soln. of K acid tartrate and Ca tartrate. It should be possible to calc. the amt. of  $\text{H}_2\text{O}$  added

to a wine by satg. it with K acid tartrate and detg. the difference between the tartrate dissolved and the added tartrate and residue. The soly. of K acid tartrate and Ca tartrate an hydro-alc. solns. with respect to temp. and content in alc. and tartaric acid, considered as variables, was investigated; also the influence of the chem. treatment and changes to which wine may be subjected. These investigations led to the belief that it is possible to show with certainty the watering of wine even with quantities as small as 5 to 10%; also to show the presence of other prohibited matter, such as  $H_2SO_4$ , in amts. too small to be detected by other analytical methods. When the  $H_2O$  added varies from 5 to 20% the method is quant. as well as qual.  $H_2O$  added to the must cannot be detected. The method is as follows: Sat. the wine with K acid tartrate and Ca tartrate separately by keeping in contact with them in excess for  $\frac{1}{2}$  hr. at 50-60°. Allow the excess of these salts dissolved to settle by cooling and, in the wine thus satd., det. the following (1) the difference in the amt. of K acid tartrate dissolved and the 2 comparative acidometric detns. made with non-satd. wine and wine satd. with K acid tartrate; (2) the amt. of Ca tartrate dissolved, with the detn. by wt. of the total Ca in the wine before and after satn.

ALBERT R. MERZ.

**Dependence of maltase-activity on the state of development of yeast.** F. SCHÖNFELD, H. KRUMHAAR AND M. KORN. *Woch. Brau.* 35, 175-6(1918); *J. Soc. Chem. Ind.* 38, 87A; cf. *C. A.* 12, 972, 973; 13, 988.—S. and K. detd. the maltase-activity of brewers' yeast taken from the vat at different stages of the primary fermentation. The maltase activity of the yeast was found to increase to more than twice its original value as the intensity of fermentation rose to its max., and to decline again at the close of fermentation. It is suggested that yeast taken from the vats at the most vigorous stage of the primary fermentation might be added to beer at the commencement of storage to stimulate the secondary fermentation, since it possesses greater maltase- and zymase-activities than the yeast which normally remains in the beer on leaving the vats.

E. H.

**Volumetric determination of phosphoric acid in brewing materials.** W. WÖLLMER. *Z. ges. Brau.* 41, 145-7(1918); *J. Soc. Chem. Ind.* 38, 86A.—Detailed procedure is described for applying the method of titration with alkali, using 2 indicators (cf. Smith, *C. A.* 11, 2079, 415; Fiehe and Stegmüller, *C. A.* 6, 3478) to the detn. of  $H_3PO_4$  in the ash of barley, malt, wort, or beer. The ash, after evapn. to dryness several times with HCl on a waterbath, is dissolved in 1 cc. of dil. HCl and filtered. The filtrate and washings, which should occupy 20-30 cc. and contain not more than 70 mg.  $PO_4$ , are treated with a drop of 0.1% methyl orange soln. and exactly neutralized with NaOH, a concd. soln. of the latter being used except for the final adjustment. Thirty cc. of 40%  $CaCl_2$  soln., exactly neutral to phenolphthalein, is then added, and the liquid is heated just to boiling, cooled to about 14°, treated with 2 drops of 1% phenolphthalein soln. and titrated, while being continuously agitated, with 0.1 N NaOH soln. free from carbonate. After a red coloration has been attained the liquid is allowed to stand at 14°; the color is slowly discharged and after 2 hrs. the titration is completed. The total vol. of 0.1 N NaOH used is reduced by 1% to allow for traces of carbonate unavoidably present; 1 cc. corresponds with 3.55 mg.  $P_2O_5$ . The method gives sufficiently accurate results with the materials named above, but is vitiated by the presence of considerable quantities of Fe, Al, Mn or borates.

E. H.

**The Plesch mashing process.** G. FRIES. *Z. ges. Brau.* 41, 73-5, 81-3(1918); *J. Soc. Chem. Ind.* 38, 86A.—This process is one of many mashing methods proposed during the war in Germany with a view to economizing material, fuel, and time. It involves the following operations: cold digestion of the finely ground malt overnight; withdrawal of a portion of the cold water ext. for future use; peptonization and saccharification of the mash; addition of hops (previously ground and digested with cold water) to the

mash; boiling of the hopped mash; filtration of the hot mash; cooling of the filtered wort and saccharification of any starch therein by addition of the cold malt ext. previously reserved; destruction of diastase by heating the saccharified wort to boiling. The wort is then cooled and fermented as usual. F. points out that, apart from the addition of hops to the mash, the process differs little from the Schmitz method of mashing (Brit. pat. 28,579, Dec. 3, 1897). The results were fairly satisfactory; the wort deposited only a small quantity of sludge on the cooler but developed a slight turbidity which necessitated the use of a filter-press. The dark beer produced was of good quality, but the economies claimed on behalf of the process have been greatly exaggerated. It is claimed that if the malt is very finely ground the wort from the boiled mash will require no further saccharification, but F. considers that the continued production of such a fine grist is beyond the capacity of any known malt mills. E. H.

Colloidal transformations in the boiling of mash and worts by direct flame and by steam. A. REICHARD. *Allgem. Brauer- u. Hopfenseit.* 1918; *Z. ges. Brauw.* 41, 141-3; *J. Soc. Chem. Ind.* 38, 86-7A.—In the boiling of brewery mash and worts the temp. of the floor of the Cu or other vessel is practically the same, about 120-130°, whether heating is effected by direct flame or steam jacket. R. describes expts. which confirm the view that these 2 methods of heating differ somewhat in their effects on the wort. Two series of lab. mashing and wort boilings were carried out in metal beakers under similar conditions except that heating was effected in one case by direct flame and in the other by a water- or brine-bath. In mashing, the former method of heating, as compared with the latter, led to more rapid saccharification and brighter worts, and in some cases to higher sugar-content and acidity of the worts. In wort boiling also, heating by direct flame resulted in improved "break," higher wort acidities, and more complete emulsification of hop resins. To account for these differences R. suggests that, even where the 2 methods of heating produce the same temp. in the mash or wort, the direct flame provides a surplus of radiant energy which is expended as work in the modification of colloidal complexes, *vis.*, subdivision of particles of colloids such as hop resins and enzymes, thus promoting contact of the latter with their substrates. E. H.

So-called carbohic odor of soured thin beer. W. WINDISCH. *Wochschr. Brau.* 35, 240-1 (1918); *J. Soc. Chem. Ind.* 38, 87A.—The appearance of turbidity of biol. origin in thin beers is often accompanied by a peculiar odor incorrectly described as "carbohic." It is probably due to reduction of nitrates present in the brewing water, by the bacteria responsible for the turbidity, and the liberation of free  $\text{HNO}_2$ . Yeast washed and stored with water contg. nitrates suffers in fermenting power, and such weakened yeast dies if stored in thin beer and acquires a somewhat nitrous odor. It is possible that the weakened yeast itself can reduce nitrates. E. H.

Carbon dioxide content of thin beers. F. SCHÖNFELD AND C. GOSLICH. *Wochschr. Brau.* 35, 167-8 (1918); *J. Soc. Chem. Ind.* 38, 87A.—The soly. of  $\text{CO}_2$  in beer decreases by 0.01% for a rise of 1°, and by 0.015% for a fall of 0.1 atm. pressure. It diminishes also with decrease in the content of sugars, dextrins, alc., and other constituents which contribute to the viscosity of beer, and is therefore lower for thin beers than for those of normal gravity. This difference may be compensated by storing thin beer under a relatively high pressure, but when the pressure is released there is apt to be a too copious evolution of gas from the beer. The retention of gas by beer is favored by absence of suspended matters. In the carbonation of thin beers, the conditions most favorable to retention of the gas are low temp., high pressure, intimate contact between liquid and gas, and subsequent storage of the beers for several days under a pressure of  $\text{CO}_2$ . E. H.

Production of turbidity in thin beer by yeasts and bacteria after carbonation with carbon dioxide containing oxygen. P. LINDNER. *Wochschr. Brau.* 35, 225 (1918); *J. Soc. Chem. Ind.* 38, 87A.—It is suggested that the frequent occurrence of turbidity in German war beers may be due to carbonation with CO<sub>2</sub> contg. O, which encourages the development of wild yeasts and bacteria. E. H.

The utilization of sisal waste for the production of alcohol. ANON. *Tropical Life* 13, No. 10, 155 (1917); *Bull. économique de l'Indochine* 21, No. 128 (1918); *Bull. Agr. Intelligence* 9, 988.—The expts. made in British E. Africa, show that it is possible to ext. alc. from sisal. An analysis of the juice of the leaves showed that the plants from the coast as well as those from the Highland contain 3% of sugar. At Yucatan the sugar content was never below 9.4%, and after a long, dry season reached 14.1%. Most of the alc. was made from leaves containing 12% of sugar. A yeast was isolated from sisal plants which fermented a glucose soln. but was quickly killed in the sisal ext., doubtless due to the large amts. of org. acids present. After neutralization with Na<sub>2</sub>CO<sub>3</sub> and the addition of a small amt. of glucose it was found possible for the yeast to live in the sisal ext., but no fermentation took place. F. W. SMITHER.

Levoglucozan; alcohol. A. PICTET. *Brit.* 121,725, Aug. 20, 1918. Levoglucozan is obtained by moderate heating of carbohydrates (cellulose, starch, dextrin, etc.), preferably by dry distn. *in vacuo*. According to examples, cellulose or starch is distd. at 200–300° at 12–15 mm. pressure, or sawdust is distd. at 30 mm. pressure; the product is isolated from the distillate, or is converted to glucose by boiling with dil. acid and the liquid then fermented to alc.

## 17. PHARMACEUTICAL CHEMISTRY.

W. O. EMERY.

An institute for coöperative research as an aid to the American drug industry. FREDERICK B. POWER. *J. Ind. Eng. Chem.* 11, 377–8 (1919). E. J. C.

Assay of red cinchona bark. W. PARTRIDGE. *Analyst* 44, 96 (1919).—To avoid the formation of pasty masses in extns. according to the Brit. Pharm. of 1914, the use of less H<sub>2</sub>O is advocated, thus 12 instead of 22 cc., when working with 10 g. portions of the powdered bark. Using this proportion of H<sub>2</sub>O higher contents of total alkaloids were obtained on 3 occasions, the increases being, resp., 2.02, 1.16 and 1.46% above the amts. found when the pharmacopeia instructions were followed. W. O. E.

Classification of the ingredients of tropical remedies. E. CROUZEL. *Repert. pharm.* 30, 67–8 (1919).—In order to facilitate the work of the physician in a rapid and rational formulation of prescriptions involving prepn. like powders, lotions, solns., liniments, mixts. and pomades, the various ingredients likely to be required are brought under the following heads: Alcohols, ethers, aldehydes, acids, alkalies and oxides, fats and soaps, hydrocarbons, salts, vegetable products, and miscellaneous products. W. O. E.

Estimation of crude filicin and filicic acid in male fern extract. PERRIN. *Repert. pharm.* 30, 65–6 (1919).—The method outlined is essentially an elaboration of procedures given in the Brit. and Swiss pharmacopeias. W. O. E.

Pharmaceutical legislation. New decree concerning the application of the law of August first 1905 relating to the suppression of frauds. *Bull. sci. pharmacol.* [2] 26, 75–86 (1919).—A transcript of the new regulations undoubtedly of interest to exporters. F. S. HAMMETT.

**Notes on the analysis and solubility of the quinine tablets sold in the colonies.**  
 V. BOUCHER. Porto-Novo. *Bull. sci. pharmacol.* [2] 26, 66-74(1919).—Ten 0.25-gram quinine tablets are dissolved in 100 cc. distd.  $H_2O$  and 25 cc. of the soln. is extd. with  $CHCl_3$  in the presence of ammonia. The sepd.  $CHCl_3$  is evapd. and dried and the residue weighed directly as quinine. There is some loss in drying which is done away with by putting 25 cc. of the soln. in 50 cc. 0.1 *N*  $HCl$ , 20 cc. of which is titrated with 0.1 *N*  $NaOH$  using rosolic acid as indicator and 20 cc. using phenolphthalein. The difference between the volumes of  $NaOH$  used times 0.0324 gives the amount of quinine in one tablet. Direct titration of the hydrochloride can be done and gives results almost identical with those obtained on the ext. A table is appended giving the amts. of quinine found in various lots assayed. A table of the soly. is also given based on the soln. in 0.09%  $HCl$  at 38° for two hours.

F. S. HAMMETT.

**The seed oils from oranges.** I. S. KOBAYASHI. *Kogyo-Kwagaku Zasshi (J. Chem. Ind. Japan)* 21, 1235-45(1918).—The air-dried seeds from the fruits of *Sinensis* Engl. (yield 2%), of *Fortunella Japonica* Swingle (3.7%) and of *Junos* Mak. (9.50%) were crushed into small pieces and the oils extd. with petr. ether. The oils were purified by steam distn. and in the latter 2 cases the oils were treated with Kambara-clay (10%) for decoloration. The phys. and chem. properties of the oils and fatty acids obtained from them, were studied.

| Seed:                    | <i>Sinensis.</i>   | <i>Fortunella.</i>    | <i>Junos.</i> |

S. KOMATSU.

**The analysis of extracts of belladonna and the unification of analytical methods.**  
 A. GORIS AND F. BRAUSSE. *Bull. sci. pharmacol.* [2] 26, 53-9(1919).—A comparison of the results obtained on exts. of belladonna using the methods of assay given in the British and French pharmacopeias shows such divergent results that a standardization of method of assay is indicated. The losses occurring when the British method is used can be traced in part to the complicated and numerous manipulations and in part to the evapn. of the volatile alkaloids. The procedure of the French Codex is recom-

mended because of its simplicity and because it gives results as total alkaloids while the British method yields only atropine and hyoscyamine. F. S. HAMMETT.

**Preparation and care of homeopathic remedies.** WILLIAM RAYMER. *Hahnemannian Monthly* 54, 158-63(1919).—The prepn. of homeopathic tinctures is described. JOSEPH S. HEPBURN.

**Erythrophleine hydrochloride as an agent for devitalizing the dental pulp.** NORMAN BLACK. Univ. St. Andrews. *Dental Cosmos* 61, 296-8(1919).—Erythrophleine occurs in the bark of *Erythrophloeum guineense* (sassy, casca, or ordeal bark). A 50% soln. of its hydrochloride in eugenol is known as throphleol, and completely devitalizes a dental pulp, on the av. in 36 hrs., usually without more than the merest suggestion of pain. It apparently acts upon the pulp by denying the latter its blood supply. JOSEPH S. HEPBURN.

**Removing nicotine from tobacco.** R. SAYRE and E. YANOVSKY. U. S. 1,294,310, Feb. 11. Tobacco is immersed in an infusion containing the constituents other than nicotine which are normally present in tobacco. After the nicotine has been extd. from the tobacco, the latter is removed from the infusion and pressed sufficiently to leave approx. the amts. of sol. constituents other than nicotine which are normally present in tobacco. The amt. of such sol. constituents present in the soln. before the tobacco is removed from it is substantially equal to the amt. originally present in the tobacco multiplied by the ratio of the amt. of the solvent used to the amt. of such solvent finally adhering to the tobacco. Nicotine is pptd. from the infusion by the addition of tannic acid or a tannate.

**Calcium tannate sparingly soluble in dilute acids.** KNOLL & Co. Ger. 306,979, 306,857, 1918. If basic Ca tannate is heated for some time at a high temp., it becomes sparingly sol. in dil. acids; a prepn. which had been heated for 6 hrs. at 140-150° had the compn.  $\text{Ca}(\text{OH})\text{C}_{14}\text{H}_8\text{O}_6$ , and is recommended for treatment of dysentery. The modification described in the second patent consists in heating solns. of tannic acid with the quantity of  $\text{Ca}(\text{OH})_2$  necessary for the production of the desired basic salt until the requisite sparing soly. of the basic Ca tannate in dil. acids is attained.

**Derivatives of cystine, soluble in water.** BERNHARD STUBER. Ger. 307,858, 1918. The sparingly sol. compds. of cystine and its derivs. with Hg,  $\text{HgCl}_2$ , or Ag are dissolved in soln. of NaCl, NaBr, NaSCN, or LiCl, and the solns. are treated with an excess of acetone, MeOH or EtOH, or ether; the ppts. are filtered and dried *in vacuo*. Complex salts of amphoteric character are obtained which are expected to find therapeutic application. The following substances are particularly described: cystine-mercury NaCl, yellow powder; cystine-mercury NaBr, brown powder; cystine-mercury LiCl, yellowish white powder; cystine-mercury NaSCN, yellowish brown powder; cystine-silver NaCl, brown powder; cystine-mercury chloride NaCl, white powder, cystine-mercury chloride NaBr, brown powder.

**Mercurous amino compounds.** SCHWEIZ. SERUM- & IMPFINSTITUT. Ger. 307,893, 1918. The compds. are prepd. by the action of one or more mols. of a mercurous salt on 1-phenyl-2,3-dimethyl-5-pyrazolone-4-sulfonamide. The substance obtained with  $\text{Hg}_2\text{SO}_4$  (1 mol.) is a grayish white, cryst. mass, which darkens and swells when heated; it is specifically lighter than  $\text{Hg}_2\text{SO}_4$ , and contains 40% Hg. On treatment with alkali it yields a ppt. of Hg and a sol. mercuric amino compd., which is pptd. by  $\text{H}_2\text{S}$  after acidification with HCl. With two mols. of  $\text{Hg}_2\text{SO}_4$  a complex substance is formed. The compds. are stable in substance and also when emulsified with fats. They have marked bactericidal and spirilloidal properties.

**Bromolecithalbumin and bromolecithin.** P. BERGELL. Ger. 307,490, 1918. Lecithalbumin is treated with Br in anhydrous, indifferent org. solvents, and, when required, the bromolecithalbumin is decomposed into bromolecithin and albumin according to the method of converting lecithalbumin into lecithin. Bromolecithalbumin is a pale yellow, almost odorless powder with a faintly acid taste and reaction; it contains about 16.6% of Br. It is transformed by Me or Et alc., slowly in the cold, more rapidly on warming, into albumin and bromolecithin contg. up to 25% of Br.

**Hydrogenated alkaloids.** C. F. BOEHRINGER & SÖHNE. Ger. 307,894, addition to 306,939, 1918 (C. A. 13, 636). The addition of H to alkaloids or their salts in the presence of small quantities of the finely divided suboxides of the Ni group at temps. not exceeding 60° can also be effected in alc. suspension or soln. The prepn. of dihydroquinine from quinine monohydrochloride and the hydrogenation of cinnamylcocaine are cited as examples.

**Concentration of sulfuric acid by the Krell-Strzoda tube system.** W. STRZODA. *Z. angew. Chem.* 31, I, 185-7(1918); *J. Soc. Chem. Ind.* 37, 688-9A.—In the Krell-Strzoda process of concn. (Brit. pat. 26,732 of 1913, C. A. 9, 1230), the concn. tubes and certain other parts are made of an acid-resisting iron enclosed in a shell of cast iron, the intermediate space being filled with an acid-proof cement, which seals any cracks which may appear in the brittle acid-resisting iron during use. The concg. tubes are arranged parallel on the slightly inclined bed of a furnace. They are connected with each other and with the distillate receiver in such a manner that the acid passes from the first tube to the second, and so on through the series to the acid cooler and receiver. The distillate is taken from the top of a crescent-shaped bend in the connection between each 2 tubes to a cooler and receiver. In a small Krell-Strzoda plant of up to 6 tubes, the production is somewhat less than 0.9 ton of 97.98% acid per tube per 24 hrs., and 0.9-1.0 ton with more than 6 tubes. The coal consumption is about 4 cwt. per ton of 97-98% acid. Instead of condensing the distillate in water-cooled lead pipes, H. Petersen passes the hot vapor up a small tower, in which it is dissolved by a descending stream of 50% chamber acid, yielding acid of 85-90%, which is then passed through the concg. app. Advantages claimed for this process are that the working conditions are easy to control, a comparatively short time is required for the construction of the plant, for subsequent repairs or renewals and cleaning, and that a colorless, clear, pure quality of acid is produced. It is essential that the tubes be kept clean and free from slime and incrustation, as otherwise they are burned and soon require renewal. E. J. C.

**Manufacture of sulfuric acid by the ferric oxide contact process.** H. DITZ AND F. KANHÄUSER. *Z. angew. Chem.* 31, I, 149-50, 153-6(1918); *J. Soc. Chem. Ind.* 37, 577A.—In the manuf. of  $\text{H}_2\text{SO}_4$  by the  $\text{Fe}_2\text{O}_3$  contact process (*Z. angew. Chem.* 15, 809-11(1902); *Z. Elektrochem.* 11, 373-84(1905); *C. A.* 2, 1864) the burner gases are first brought into contact with  $\text{Fe}_2\text{O}_3$  at a high temp., 50 to 60% of the  $\text{SO}_2$  being converted into  $\text{SO}_3$  while the As is retained by the contact mass. The gases are then cooled, and, after absorption of the  $\text{SO}_3$  by means of  $\text{H}_2\text{SO}_4$ , are brought into contact with a Pt mass whereby the oxidation is completed. Samples of  $\text{H}_2\text{SO}_4$  deposited in the fan casing of a plant had the following compn.:  $\text{H}_2\text{SO}_4$ , 97.82 and 97.01;  $\text{PbSO}_4$ , 1.28 and 1.04; Fe, 0.104 and 0.006;  $\text{SeO}_2$ , 0.161 and 0.058; selenic acid, 0.008 and 0.014;  $\text{As}_2\text{O}_3$ , 0.014 and 0.007; and  $\text{SO}_2$ , 0.012 and 0.064%, resp. Expts. showed that  $\text{PbSO}_4$  when heated with  $\text{H}_2\text{SO}_4$  alone, was only slightly volatile, but that in the presence of elementary Se or  $\text{SeO}_2$ , the volatility was greatly increased. The high proportion of Pb in the acid was contrary to recorded statements of Lunge and Marshall, but the authors have shown (*C. A.* 11, 554) that 98 to 100%  $\text{H}_2\text{SO}_4$  is able to dissolve a large proportion of Pb. The presence of Se has probably an unfavorable influence on the oxidation of the  $\text{SO}_2$ . The process should convert up to 95% (usually about 92%) of the S burned, but in a plant studied the yield was sometimes less than 90%. This was probably partly due to the toxic action of the As in the gases upon the Pt contact mass, but it was also possible that Se and Pb compds. in the burner gases had an influence on the activity of the  $\text{Fe}_2\text{O}_3$  contact mass.

E. J. C.

**Some observations on sulfuric acid plants (new and old).** IX. "P." *Gas World* 70, No. 1806 (Coking and By-products Sec.) 18-9(1919); cf. *C. A.* 13, 771, 891.—Marketing and burning of pyrites are discussed.

J. L. WILEY.

**New ammonia synthesis.** H. HAMPEL AND R. STEINAU. *Chem. Ztg.* 42, 489 (1918); *J. Ind. Eng. Chem.* 11, 368(1919).—Particulars given are meager and the app. is not described. The authors point out that both the H and N should be used in the at., not the mol. state. The H is generated and used in the nascent condition; whether or how they dissociate their N is not stated. They start from  $\text{NH}_4\text{Cl}$  which is heated in presence of iron filings and decomposes thus:  $\text{Fe} + 2\text{NH}_4\text{Cl} = \text{FeCl}_2 + 2\text{NH}_3 + 2\text{H}$  and this H is the H utilized. When the reaction takes place in presence of N, the H is bound according to the equation  $3\text{Fe} + 6\text{NH}_3 + 6\text{HCl} + 2\text{N} = 3\text{FeCl}_2 + 6\text{NH}_2 + 2\text{NH}_3$ , and this reaction gives 2 mols. of  $\text{NH}_3$  more than the  $\text{NH}_3$  started with. This constitutes the yield of the method. The 6 mols. of  $\text{NH}_3$  are passed into the soln. of the  $\text{FeCl}_2$  to ppt. the Fe as hydroxide while the  $\text{NH}_4\text{Cl}$  is recovered and the  $\text{Fe}(\text{OH})_2$  is reduced by water gas.

E. J. C.

**Potash from brackish lakes in South Plains region of West Texas.** ANON. *Manufacturers Record* 75, No. 13, 87(1919).—The salt-encrusted surfaces of many of these lakes contain potash in com. percentages. An exploitation scheme is discussed.

E. J. C.

**The potassium problem and the utilization of olive oil residue in Italy.** G. L'ABATE. *Bull. Agr. Intelligence* 9, 931(1918).—Sources of K in Italy are the mother-lyes of the salt-springs, the leucites of Latium, the ashes of wood and other vegetable products (almond shells, exhausted olive cake), distillery waste and the hitherto untested source, the residue from the manuf. of olive oil. Samples of this from the province Bari gave, per l.:  $\text{H}_2\text{O}$ , 884-891 g.; mineral matter, 30.65-35.48 g.; org. matter, 79.85-80.60 g.; fat, 10.50 g.; N, 10.0 g. The ash obtained from this gave:  $\text{H}_2\text{O}$ -sol. matter, 80.31%;  $\text{H}_2\text{O}$ -insol. matter, 19.09% (C, Si, CaO, MgO and 8%  $\text{P}_2\text{O}_5$  combined with Ca, Fe and Al);  $\text{K}_2\text{CO}_3$ , 55.15%;  $\text{Na}_2\text{CO}_3$ , 2.57%; KCl, 21.89%;  $\text{K}_2\text{SO}_4$ , trace;  $\text{H}_2\text{O}$  and undetd., 20.39%. This gave a refined product containing 68.88%  $\text{K}_2\text{CO}_3$ , 27.27% KCl

and 3.2%  $\text{Na}_2\text{CO}_3$ . The olive oil residues of Apulia give more than 30 g. K salts per l. with 48% of K as carbonate (50–60%) and chloride (15–20%). They represent almost 3 times the amt. of oil produced or 30–40% of the wt. of the olives. If all the residue in Italy were used 294,000 cwt. of crude K salts would be obtained. The N may also be utilized as  $(\text{NH}_4)_2\text{SO}_4$  and KCN (secured by Effront's method). The treatment of the residues in factories is essentially a problem of transport. ALBERT R. MERZ.

**Potash recovery.** N. H. GELLERT. Philadelphia. *Chem. Met. Eng.* 20, 308–9 (1919).—A comparison is made of the data published by Grasty (*C. A.* 13, 61) and by Bradley (*C. A.* 13, 61) on the production and cost of recovery of  $\text{K}_2\text{O}$  as a by-product in the blast furnace industry. Although using practically the same original data, it is shown that both authors arrive at entirely different conclusions respecting the amt. and value of the recoverable  $\text{K}_2\text{O}$ . Estimates are given of the cost of operating the Cottrell system for the removal of the dust from blast furnace gases, and it is considered that the net revenue derived from the  $\text{K}_2\text{O}$  that is recovered in the dust should yield profitable returns even if the price of the  $\text{K}_2\text{O}$  were to drop to a value of \$1.00 per unit.

W. H. ROSS.

**Future of the potash industry.** J. W. TURRENTINE. Summerland, Calif. *Chem. Met. Eng.* 20, 310–11 (1919).—A plea for scientific organization and coöperation in the development of American potash.

W. H. ROSS.

**The water hyacinth as a source of potash.** F. W. F. DAY. *Agr. Bull. Federated Malay States* 6, 309–14 (1918).—The variable results obtained in previous work (Finlow and McLean, *C. A.* 11, 3088) for the  $\text{K}_2\text{O}$  content of the water hyacinth is attributed to the presence of variable amts. of fine particles of silt, etc., which are incorporated in the roots, or otherwise adhere to the plant, and which may very greatly increase its apparent ash content. When freed from roots and extraneous matter the ash of the sun-dried plant should amount to about 15%, and contains approx. 25% of  $\text{K}_2\text{O}$  which gives about 3% as the  $\text{K}_2\text{O}$  content of the dried plant. The  $\text{K}_2\text{O}$  in the ash of samples consisting mostly of stalks is almost entirely water-sol., and is present principally as the chloride. In other samples yielding a higher % of ash, a portion of the  $\text{K}_2\text{O}$  was found to be insol. and is thought to be derived from feldspathic particles contained in the ash. The av. value found for the  $\text{P}_2\text{O}_5$  content of the ash amounted to 0.6%.

W. H. ROSS.

**The potassium salts industry in war time.** LOUIS BRANET. *Rev. gén. sci.* 29, 175–84 (1919).—B. discusses the uses of K salts in fertilizers and the effect of the war in developing new or little used sources of supply to counteract the disappearance of German salts from the market. Considerable detail is given regarding the locations of new mineral deposits, the extn. of K salts from sea and saline lake waters, the treatment of insol. rocks and minerals to obtain sol. K salts, the recovery of K from cement and blast furnace dust, and the processing of wood ashes, turnesol stems, banana scrapings, potato leaves, waste liquors from beat-sugar refineries and wool-scouring establishments, marine algae and other animal and vegetable substances for their K content.

ISMAR GINSBERG.

**Water-glass manufacture.** O. MAERTZ. *Chem. Ztg.* 42, 569–70, 582–3 (1918); *J. Soc. Chem. Ind.* 38, 72A.—In the manuf. of  $\text{Na}_2\text{SiO}_3$ ,  $\text{Na}_2\text{SO}_4$  is now generally used in place of  $\text{Na}_2\text{CO}_3$  on account of its lower price, although a greater wt. has to be used in addition to a quantity of coal as a reducing agent, while it has a more destructive action on the furnace walls than carbonate. The materials are used in the proportion of sand 100,  $\text{Na}_2\text{SO}_4$  75, and coal 8 parts. The finely ground mixt. is fused at about  $1500^\circ$  in a tank furnace constructed of firebrick, the bottom being cooled externally by air-ducts connected with the chimney. The furnace proper communicates with a second

compartment by means of a hole at a distance from the bottom  $\frac{1}{4}$  the depth of the charge. The fused glass falling to the bottom of the furnace, flows into the second compartment, which may be separately heated to keep the water-glass molten, and is thence discharged into an Fe vessel filled with water to cool it. The furnaces are fired with producer gas and may be worked on the recuperative or the regenerative system, the former being suitable for small plant with a daily output of 1500-5000 kg., while for larger installations, up to 20,000 kg. per day, the regenerative system is better. The solidified water-glass is broken up into fairly small particles, usually by means of hammers. (It is not now generally ground in a ball mill as the finely divided particles ball together during the extn. process and then only dissolve with difficulty.) The broken product is then transferred to the dissolving drums, in which it is treated with steam at about 5 atms. pressure, while the drums rotate at about 6 revolutions per min.; the soln. process takes about 6 hrs. The capacity of the drums should be in the proportion of 1 l. to 1 kg. of dissolved glass, so that, the sp. gr. of the water-glass being 1.5, the drum is  $\frac{2}{3}$  full at the end of the process. A convenient capacity is 6000 l. For each kg. of solid glass about 1.5-2 kg. of steam is used. When soln. is complete the product is run off into settling tanks and, after the mud has settled, passed through a filter-press. The clear water-glass so obtained generally has to be concd., this being carried out in a closed steam-jacketed vessel connected to a vacuum pump, the soln. being stirred during concn. to obtain a homogeneous product. Cf. C. A. 12, 1414. E. H.

**The phosphate production and resources of the world.** P. G. MORGAN. *J. Agr. (New Zealand)* 16, 76-82(1918); *Expt. Sta. Rec.* 39, 521.—This is a summarized discussion of available information obtained from various sources relative to the world's production and supply of phosphates. E. H.

**How the nitrogen problem has been solved.** HENRY JERMAIN MAUDE CRRINGTON. Swarthmore College. *J. Franklin Inst.* 187, 377-408(1919).—An elaborate account of the fixation of atm. N on a commercial scale as oxides in the arc processes, and as  $\text{NH}_3$  by direct combination with H. JOSEPH S. HERBURN.

**Novel method for treating sulfur ore.** K. THOMAS. *Chem. Met. Eng.* 20, 261 (1919).—A brief discussion of the attempts to develop and operate western S deposits, mostly of solfataric origin and not adapted to the Frasch process. There is promise of good results by flotation. One of the ideas evolved is based on the "shot-tower" principle. The S with the gang is submitted to treatment under pressure of superheated steam, with the result that the S is liquated and drains through the perforated bottom of the retort along with more or less of the fine gang and dirt, the sepn. of which from the liquid S is one of the problems of other liquation applications. In falling a short distance, not more than 10 ft., the S forms small spheres in a similar manner to the action of the streams of molten Pb in the shot tower, and at the bottom of the chamber there is accumulated a mixt. of these "shots" and the fine material. The S "shots" are very pure and free from dirt and fine rock. Their further sepn. is an easy matter. F. W. SMITHER.

**Furnace settings for caustic pots.** F. H. NICKLE. *Chem. Met. Eng.* 20, 261 (1919).—A note stating that the words "counter-current" should have been omitted in the original article (cf. C. A. 13, 637), the direction of travel being concurrent with the rotation of the liquor. F. W. SMITHER.

**Concentration of graphite ore.** G. D. DUB. *Mining Sci. Press* 18, 283-6(1919).—Four methods are used for the rough concn. of graphite ore, the skin flotation, the pneumatic, the log washer, and the oil froth flotation systems. The crude concentrate usually contains 40-60% graphitic C, the impurities consisting of quartz, mica, wood

fiber, etc. This concentrate is refined pneumatically to No. 1 flake after grinding in a pebble mill if necessary to detach the impurities from the C. The av. final products in Alabama are No. 1 flake contg. 87% C, No. 2 flake with 77%, and dust with 30% C. A ton of ore yields, respectively 19, 5 and 3 lbs. of these grades, the recovery totaling 42.56%.  
E. SCHRAMM.

**Production of hydrogen and water glass by the silicol process.** ANON. *Chem. Met. Eng.* 20, 289-90(1919).—An illustrated description of a British Admiralty H plant. The installation contains a vat provided with a stirring device for prepg. the NaOH soln. The lower part of the vat is fitted with a pipe provided with a valve and ending in a gas generator; the latter is fitted with a "planetary stirrer," and has at its top part a receiver containing the Si alloy (Fe-Si, Mn-Si, silico-spiegel). The receiver has a hopper-shaped base in which acts a distributor worked by a crank. The NaOH is put in the vat to the extent of  $1\frac{1}{2}$  to 2 times the wt. of NaOH to that of H<sub>2</sub>O and the stirrer started; the heat evolved raises the temp. of the soln. to 60 to 80°. The soln. is then led into the gas generator, which it should reach at a temp. sufficient to start the reaction on contact with the Si alloy. The "planetary stirrer" causes the Si alloy powder falling from the hopper-shaped base of the receiver to come into intimate contact with the NaOH soln., and prevents it from accumulating in the center of the generator. The H gas, evolved at a high temp., flows into a scrubber-condenser, where it loses H<sub>2</sub>O vapor and is cooled at the same time. The H gas then flows out through a pipe for utilization. The H<sub>2</sub>O used for cooling the gas in the scrubber-condenser, which leaves this at a temp. near the b. p., is recovered and utilized in the vat or gas generator. Where a weak NaOH soln. is used, a neutral Na silicate is formed; with a concd. soln., an acid silicate poorer in Na is obtained; this leads to a saving in NaOH and allows the obtaining of non-caustic residues which can be utilized for dyeing and bleaching. The products may be utilized in peace times for the hardening by hydrogenation of oils and in oil refining by the water glass method.  
F. W. SMITHER.

**The use of helium for aircraft purposes.** ANON. *Nature* 102, 487-8(1919).—A review of the principal steps that have been taken in Great Britain for the production of He for use in air ships and for other purposes.  
W. H. ROSS.

**Industrial value of the material of the national powder mills.** ANON. *l'Industrie chimique* 6, 51-2(1919).—A discussion of the ways in which various materials accumulated during the war may be utilized by the industries and by the State for the public welfare.  
F. W. SMITHER.

**Chemical war secrets and releasing manufacturers' rights.** EDWARD GUDEMAN. *Trans. Am. Electrochem. Soc.* 35 (preprint).—The attitude the government should now take towards valuable chem. information divulged to it by individuals and corporations during the progress of the war is discussed.  
H. JERMAIN CREIGHTON.

**Lubrication of air compressors.** H. V. CONRAD. *Eng. Mining J.* 107, 392-4 (1919); *Textile World J.* 55, 79(1919); *Sugar* 21, 125-7(1919).—In choosing a lubricant for air cylinders, the high temp. reached must be kept in mind. Faulty lubricants make trouble mainly by carbonizing. This interferes with valve action, causes undue friction, and may be a fire risk in case the oil is heated above its flash point. For paraffin base oils the following limits are set: Sp. gr. (Bé.) 25 to 32; open cup flash point, 375 to 500° F.; fire point, 425 to 575° F.; Saybolt viscosity, 120 to 1500 sec. For asphaltic base oils the corresponding limits are 19.5 to 22° Bé.; 305 to 375° F.; 360 to 440° F.; 175 to 750 sec. Vegetable or animal oils are to be avoided. Asphaltic base oils are more apt to carbonize, but asphaltic oils give a bulkier and less dense deposit. For a few hrs. once a week the air cylinder should be fed with a mixt. of 1 pt. soft soap to 15 pts. H<sub>2</sub>O, used at about 10 times the rate of oil feed, and kept up for several hrs.

to cut out the C. Air receivers and piping should have a 1:18 mixt. of NaOH and H<sub>2</sub>O injected occasionally to keep down deposits. Air cylinders should have from 1 drop oil per min. for an 8 × 8 cylinder to 12 drops for a 42 × 42 cylinder. Steam cylinders should have about 4 times as much. W. L. BADGER.

An investigation of stench and odors for industrial purposes. V. C. ALLISON AND S. H. KATZ. *J. Ind. Eng. Chem.* 11, 336-8(1919).—A detailed account of an investigation of the use of stench as a warning in mines. The authors have developed an app. or "odorometer," for measuring the intensity of odors in varying concns. in air. A table and curves are given showing the results obtained with 24 different chemicals. F. W. SMITHER.

ROCKWOOD, NATHAN C.: Index to "Engineering News" for the Years 1910 to 1917 Inclusive. New York: McGraw-Hill Co. 469 pp. \$3 net or \$6 in combination with indexes for 1890-99, 1900-04, 1905-09. For review see *Eng. News-Record* 82, 779(1919).

---

Concentrating sulfuric acid. A. B. NEWMAN. U. S. 1,294,525, Feb. 18. H<sub>2</sub>SO<sub>4</sub> to be concd., which may be of a strength of 60° B $\acute{e}$ ., is distd. and the distillate is introduced into the flue system from the roasting furnace to the Glover tower so that a sufficient amt. of heat is derived from the highly heated gases in the flue system to maintain the distillate above its temp. of condensation during its passage through the flue system. The distillate is recovered in the Glover tower or in the succeeding chambers.

Concentrating sulfuric acid. J. PATTEN. U. S. 1,294,827, Feb. 18. The acid to be concd. is fed into the first of a connected series of concentrators. This first concentrator is heated by first contact with hot furnace gases which then pass successively beneath the other concentrators of the series.

Hydrofluoric acid. R. M. CATLIN. U. S. 1,293,703, Feb. 11. HF is produced from solns. containing H<sub>2</sub>SiF<sub>6</sub> or other combinations of F and Si by adding Fe oxide to the soln., removing the ppt. formed, crystg. out Fe fluoride from the filtrate and then subjecting the Fe fluoride to the action of superheated steam to drive off HF. The latter is absorbed in H<sub>2</sub>O. The Fe oxide preferably is added to the soln. of H<sub>2</sub>SiF<sub>6</sub> at a temp. of about 93°.

Apparatus for condensing hydrofluoric acid. R. S. SHERWIN. U. S. 1,294,546, Feb. 18. The app. comprizes a first absorbing tower made of material, such as wood, which is resistant to the action of HF, containing baffles which break up and subdivide the liquid falling through the tower and which are spaced further apart in the lower than in the upper part of the tower, coolers for independently cooling the liquid flowing into and out of the tower, a second absorption tower and connections for withdrawing liquid from the latter to an open vessel, from which the liquid may be re-introduced into the second tower.

Alkali metal silicates from rice hulls. G. BLARDONE. U. S. 1,293,008, Feb. 4. Burned rice hulls 4-5, H<sub>2</sub>O 10 and NaOH 1 part are boiled together for a half hr. or longer and a soln. of Na silicate thus obtained is filtered and concd. by boiling. Na silicate may also be obtained by fusing together 3 or 4 parts of burned rice hulls and 1 part Na<sub>2</sub>CO<sub>3</sub> (or 8 or 10 parts of burned rice hulls and 3 parts Na<sub>2</sub>SO<sub>4</sub>) and extg. the product

with  $H_2O$ . Fresh or only partially burned rice hulls may be similarly treated and  $KOH$  or other K compds. may be used (instead of the Na compds.) to obtain K silicate.

**Sodium hydrogen carbonate and ammonium sulfate from sodium bisulfate.** G. N. VIS. U. S. 1,294,526, Feb. 18.  $NaHSO_4$  is dissolved in  $H_2O$  and the soln. is successively treated with  $NH_3$  and  $CO_2$  under slight pressure until satn. is complete, forming  $(NH_4)_2SO_4$  and  $NaHCO_3$ .

**Alkali metal cyanides.** F. J. MERTZGER. U. S. 1,295,049, Feb. 18. After production of cyanide by the action of N upon a mixt. formed of alkali metal carbonate and coke, charcoal or other carbonaceous material, the reaction product is treated with acetone or dil. alc. or other solvent which will dissolve alkali metal cyanide and hydroxide but in which alkali metal carbonates are relatively insol. and the soln. thus obtained is then treated with  $CO_2$  under slightly greater than atm. pressure to convert the hydroxide into carbonate (of decahydrate form) and cause the pptn. of the latter. The soln. is then filtered off from the ppt. and evapd. to recover the cyanide.

**Separating sodium nitrate from potassium nitrate.** G. C. GIVEN and R. H. BARTEAUX. U. S. 1,294,788, Feb. 18. A soln. containing nitrates of both Na and K is evapd. *in vacuo* at a temp. of about  $80-95^\circ$  until some  $NaNO_3$  is sepd. and the  $KNO_3$  is then sepd. from the concd. soln. remaining.

**Production of nitrates by means of bacteria.** CARL T. THORSSELL and H. R. LUNDEN. Can. 189,602, Apr. 15, 1919. A nutrient medium inoculated with nitrifying bacteria is treated with a material which is not injurious to the nitrifying bacteria and which is adapted to destroy bacteria which are injurious to the nitrifying bacteria and the product thus obtained is introduced into  $NH_3$  combinations to be oxidized.

**Production of nitrates by means of bacteria.** CARL T. THORSSELL, *et al.* Can. 189,600, Apr. 15, 1919. A liquid nutriment containing  $CaCO_3$ ,  $Ca(NO_3)_2$  and an  $NH_4$  salt is inoculated with nitrifying bacteria to effect oxidation and the formation of a liquid containing  $Ca(NO_3)_2$ . A portion of the liquid is withdrawn, treated with an  $NH_4$  salt and  $CaCO_3$  and again inoculated with the nitrifying bacteria.

**Catalytically active substances.** F. MÜLLER. Ger. 207,380, 1918. Werner's salts (*i. e.*, the double salts of the heavy metals and complex salts described by Werner, *Neuere Anschauungen auf dem Gebiete der organischen Chemie*, 1913) are heated with exclusion of air at a temp. not exceeding that at which the catalyst is intended to be used. Heating may occur in a current of N or in a vacuum; if the product is to be used as catalyst for reaction between gases, the heating may take place in an atm. of one or all of the gases. Previous to heating, the substance may be distributed over carriers, such as clay or asbestos. For reactions between liquids and gases, the heating may proceed in the liquid after the salt has been dissolved, suspended, or emulsified. In many cases, it is necessary to heat under pressure. A catalyst from K chromicyanide at  $300^\circ$  gave 15% of ammonia at  $300^\circ$  and 120 atm. Ammonia undergoes quant. combustion in the presence of the product from luteochromium ferricyanide at  $300^\circ$ .  $NH_4$  ferrimolybdate when heated at  $400^\circ$  in an atm. of N and H yields a loose, black powder which yields 19% of  $NH_3$  at 160 atm. and  $400^\circ$ .  $NH_4$  Na cobaltcyanide is converted by ignition at  $700^\circ$  in N into a very porous, black catalyst for the synthesis of  $NH_3$ . Carbonatopentamminocobalt nitrate is heated at  $420^\circ$  in a current of N and H for the prepn. of a catalyst. Up to 8% of formaldehyde could be obtained from  $CH_4$  and O at  $150^\circ$  by use of a catalyst from croceocobalt nitrate (heated in N at  $150^\circ$ ). The catalyst from nitratopurplecobalt nitrate is useful in the synthesis of  $NH_3$ . Indole is formed by hydrogenation of Me *o*-toluidine in the presence of the catalyst from hexaquochromi-acetate. Borneol is converted into camphor in the presence of a product from hexa-

quochromipropionate. A catalyst from Co hydroxynitrite brings about the quantitative oxidation of  $\text{SO}_2$  to *sulfur trioxide* by an excess of O.

**Zinc oxide and chloride.** S. SANDERS. Brit. 121,984, Nov. 27, 1917. Galvanizer's waste flux is broken up and boiled with  $\text{H}_2\text{O}$ ,  $\text{ZnO}$  being removed from the surface as a froth. The liquor is then allowed to settle, a little  $\text{CaO}$  being added if desired. The sediment is washed to sep. particles of metal, the other portion of the sediment being mixed with a binding agent such as a bleaching powder residue obtained in the treatment of the clear soln., and formed into *fireproof articles*. The settled soln. is clarified over a bed of bleaching powder and may be used for *fireproofing*.

**Production of alumina.** RALPH H. MCKEE. Can. 189,848, Apr. 22, 1919.  $\text{Al}_2\text{O}_3$  is removed from Al materials containing Fe and native basic sulfates of Al by dissolving the material in an acid solvent, fractionally removing Fe by electrolysis and then electrically pptg. the Al as hydroxide and simultaneously regenerating the acid solvent for reuse in the initial step.

**Regenerating mercury catalysts.** H. A. MORTON. U. S. 1,293,863, Feb. 11, 1919. Mercury catalysts (such as those which may have been used in making  $\text{AcH}$  from  $\text{C}_6\text{H}_6$ ) when exhausted are regenerated by treating with  $\text{Cl}$  to form  $\text{HgCl}_2$  and then sepg. the latter and converting it into the desired compd., e. g.,  $\text{HgSO}_4$ , for further catalytic use.

**Hydrogen peroxide.** DAVID LEVIN and L. L. MOLIN. Can. 189,193, Mar. 18, 1919. In the production of  $\text{H}_2\text{O}_2$  by film distn. of persulfates the soln. is sprayed over heated  $\text{H}_2\text{SO}_4$ -proof metallic surfaces on which an unbroken film is maintained by the rapid rate of flow of the liquid and the  $\text{H}_2\text{O}_2$  is condensed quickly enough to prevent dissociation.

**Methods of conducting high-temperature reactions.** N. TESTRUP. Can. 189,586, Apr. 8, 1919. The substance to be roasted is placed in a continuous layer on a conveyor which travels below and parallel with the level to which the walls of the heating chamber depend. The thickness of the layer is greater than the distance between the surface of the layer and the bottom level of the walls of the heating chamber so that the latter sweeps a recessed path for itself in the moving layer. App. is specified.

**Dental filling.** H. A. BLACK. U. S. 1,294,355, Feb. 11, 1919. A powdered mixt. for prepg. dental fillings is composed of nitrocellulose 100, gum amber (measured as a satd. soln. in  $\text{CHCl}_3$ , the  $\text{CHCl}_3$  being evapd. in the prepn. of the powder) 40 and powdered  $\text{SiO}_2$  25 parts. When this mixt. is to be used for filling cavities, it is made into a plastic mass by the addition of a solvent mixt. composed of acetone 2 parts and a satd. soln. of gum amber in  $\text{CHCl}_3$  1 part.

**Casein composition for imitations of porcelain.** M. PONTIO. U. S. 1,293,191, Feb. 4, 1919. A compn. for making doll heads or other molded articles is formed as follows: Casein 10 parts is dissolved in an aq. alk. soln., together with gelatin 10 and gum arabic 2.5 parts, mixed with a white mineral powder such as talc, plaster of paris, Spanish white or Meudon white, and the mixt. is molded and then hardened in a bath of  $\text{CH}_3\text{O}$  soln.

**Lubricant for treating transmission-bands.** C. J. JOHNSON. U. S. 1,293,107, Feb. 4, 1919. Fabric straps for use as transmission-bands are boiled in a mixt. of graphite 50, paraffin 45 and grease 5%, to render them pliable and non-hardening.

**Reclaiming printers' roller composition, etc.** T. H. GROZIER. Brit. 121,941, June 28, 1918. A process of sepg. the fusible from the infusible parts of old printer's roller compn. or analogous substances consists in treating the compn. by the direct action of low-pressure superheated steam in a closed vessel and intercepting and vaporizing the  $\text{H}_2\text{O}$  of condensation to prevent its admixt. with the recovered compn.

**Measuring pressure between bodies.** AKTIEBOLAGET SVENSKA KULLAGER, FABRIKEN. Brit. 121,946, Dec. 19, 1918. The pressure between bodies in contact, which bears a definite relation to the deformation produced, is detd. by etching the portions around the surface of contact while under pressure and deducing the pressure from measurements of the unaffected parts. An etching liquid for Fe and steel bodies is prepd. in the following manner.  $MgCl_2$  is dissolved in boiling  $H_2O$  and  $CuCl_2$  is added. The combination is stirred into a soln. of  $BiCl_3$  in  $HCl$ , and alc. is added. Proportions of these substances are set out in the specification.  $Cl$  gas may be used for the same purpose.

## 19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLEININGER.

**Strength tests of plain and protective sheet glass.** T. L. SORBY. *J. Am. Ceram. Soc.* 1, 801-8(1918).—*Rifle Tests:* Plate glass  $1/8"$ ,  $3/16"$  and  $1/4"$  thick and blown brown glass  $3/16"$  thick were tested (a) in original condition and (b) with a sheet of celluloid firmly attached to the back. Shots from army rifle were fired at 50 ft. All plain samples (a) shattered badly while samples (b) showed fairly clean cut holes. In *impact testing* by a pendulum method it was shown that the first crack appeared about as soon in the coated as in the uncoated samples but the coated glass shattered less. In *cross-breaking tests* the coated glass was about 15% weaker than plain glass when the coated side was in compression and about 40% stronger when the coated side was in tension. In both impact and cross-breaking tests blown glass was stronger than polished plate glass.

C. H. KERR.

**Some incidental notes of a flint-glass works manager from 1875 to 1916.** HARRY J. POWELL. *J. Soc. Glass Tech.* 2, 241-6(1918).—A partial history of Whitefriars Glass Works, London. Expts. with "toughened" glass were started by de la Bastie in 1875. Pot stones were identified in 1876. Pyrometers were successfully used in 1876. Good X-ray tubes were made in 1896. Expts. on thermometer glass were started in 1897. Anticataract spectacle glass, cutting out infra-red and ultraviolet rays, was made for Sir Wm. Crookes in 1911. The notes are most interesting. C. H. KERR.

**Cherry-red glass direct from the pot.** ANON. *Spektsaal* 50, 126(1917); *J. Soc. Glass Tech.* (Abstracts) 2, No. 5, 9(1918).—A formula is given for a mix to be fused, ground and re-fused with addition of Pb glass or cullet. The color is intensified by annealing.

R. K. HURSH.

**Opal glasses from cryolite or cryolite substitutes.** *Spektsaal* 50, 125(1917); *J. Glass Tech.* (Abstracts) 2, No. 5, 8-9(1918).

R. K. H.

**Barium carbonate as a constituent of a glass batch.** ANON. *Spektsaal* 50, 148(1917); *J. Soc. Glass Tech.* (Abstracts) 2, No. 5, 9(1918).

R. K. H.

**Glass-house pots for sheet glass.** *Spektsaal* 50, 125(1917); *J. Soc. Glass Tech.* (Abstracts) 2, No. 5, 10(1918).—A discussion of pot mixts. The ratio of plastic to burned clay should not be less than 5 to 6.

R. K. HURSH.

**Open glass-house pots for melting sheet glass.** *Spektsaal* 50, 270(1917); *J. Soc. Glass Tech.* (Abstracts) 2, No. 5, 10(1918).—A discussion of the proper dimensions of pots.

R. K. HURSH.

**Etching solutions without hydrofluoric acid.** ANON. *Spektsaal* 50, 251(1917); *J. Soc. Glass Tech.* (Abstracts) 2, No. 5, 20-1(1918).—Fluorides, sulfate and  $HCl$  or  $H_2SO_4$  are recommended.

R. H. KURSH.

**Refractory materials and the glass industry.** J. W. COBB. *J. Soc. Glass Tech.* 2, 262-70(1918).—An excellent general review. C. H. KERR.

**Glasses for protecting the eyes from injurious radiations.** W. W. COBLENTZ AND W. B. EMERSON. Bur. of Standards, *Tech. Paper* 93, 25 pp.(1919).—This paper is published with the object of supplying the general characteristics of certain newly developed glasses sometimes used for protecting the eye from radiant energy, especially the infra-red rays. An appendix gives transmission data of various glasses obtained in collaboration with M. B. Long. E. J. C.

**Notes on the welding of glasses.** LEON APPERT. *Bull. soc. encour. ind. nat.* 131, 67-91(1919).—A. reviews in general terms the welding of glasses and the enameling of metals. The most important factors are coeff. of expansion, permeability to heat and absence of reactions or alterations during welding. These points are discussed at length. Enamel coats to be most serviceable should be built up of many thin coats successively applied. C. H. KERR.

**The relative action of acids on enamels.** E. P. POSTE. *J. Am. Ceram. Soc.* 2, 32-43(1919).—The dil. acids are more active than the concd., the max. being about 20%. Acetic acid shows unexplained irregularities at about its max. activity and this plus the varying strength as usually sold make it undesirable as a standard testing acid. Citric and tartaric acids are more active than acetic. Above 10 up to 50% both show practically horizontal straight line curves of solvent action so that small errors in concn. are of small importance. Tartaric is more stable than citric acid but either would be satisfactory as standard acid. C. H. KERR.

**Refractory materials as a field for research.** EDWARD W. WASHBURN. *J. Am. Ceram. Soc.* 2, 3-31(1919).—An hypothetical research association or corporation for the entire industry is outlined and the general nature of problems and correlation with other organizations is discussed. The fundamental problems of refractories are outlined. C. H. KERR.

**Fusibility of graphite ash and its influence on the refractoriness of bond clay.** M. C. BOOZE. *J. Am. Ceram. Soc.* 2, 65-8(1919).—Softening point of graphite ash is not a true index of its action in a crucible. Any lowering of refractoriness of a crucible due to graphite ash is not evident at brass-melting temps. and would seldom be detrimental even in steel-melting crucibles. The ash from Alabama graphite is less active as a flux than ashes of Ceylon, Canadian, Pa., or N. Y. graphites. C. H. KERR.

**Some apparatus used in the laboratory control of the manufacture of silica brick.** H. LECHATLIER AND B. BOGITCH. *Rev. metal* 15, 511-31(1918).—The most important properties are (1) chem. compn., (2) density, (3) crushing strength, cold, (4) expansion and crushing strength at 1600°. Method for ultimate analysis is given. Best quality bricks contain about 1% each CaO, Al<sub>2</sub>O<sub>3</sub> and Fe<sub>2</sub>O<sub>3</sub> with 97% SiO<sub>2</sub>. To stand in the arch of a steel furnace at 1700° the SiO<sub>2</sub> content should be over 95% and preferably 97%. The d. of good bricks should be from 2.30 to 2.40. A form of cement sp. gr. bottle is described for use on SiO<sub>2</sub> and details are given. Good crushing strength when cold is important; 100 kg. sq. cm. is a safe min. while excellent bricks show 200-300 kg. Failure of bricks in a steel furnace is due chiefly to (1) expansion and consequent disruption and (2) partial fusion. Lab. testing furnaces are described in detail, especially a recuperative furnace. C. H. KERR.

**Clays for paper making (ROE) 23. Relative volatilities of refractory materials (MOTT) 4. System CaO-MgO-SiO<sub>2</sub> (FERGUSON, MERWIN) 6.**

**Packing glass.** E. B. BROGLEY. U. S. 1,293,684, Feb. 11. Before packing

glass in straw for shipment, the glass is coated with a mixt. formed of  $H_2SO_4$  1, lubricating oil 1 and  $H_2O$  128 parts to prevent discoloration of the glass by the decompn. products of the straw.

**Glass-making apparatus.** T. J. MCCOV. Can. 187,944. Dec. 17, 1918. Structural features.

**Magnesite refractories.** ROBERT D. PIKE. Can. 189,142, Mar. 18, 1919. A metallic deoxidizer such as a ferro alloy is mixed with magnesite and the mixt. is heated to cause the alloy to react with the magnesite. If necessary,  $Fe_2O_3$  may be added to the mixt. When water is added the product may be molded into any desired shape.

**Refractory composition.** H. M. OLSON. Can. 189,135, Mar. 18, 1919. The material consists of finely divided infusorial earth,  $Na_2SO_4$ ,  $Al_2(SO_4)_3$  and  $CaO$ .

**Refractory articles.** F. J. TONE. Can. 189,191, Mar. 18, 1919. A refractory containing fireclay and less than 60%  $SiC$  which is largely retained on a 60-mesh screen, is used for making saggars which have little or no deleterious influence on the ware brought into contact with them. With the proportions used the  $SiC$  crystals are surrounded by a film of clay which prevents action of the  $SiC$  on the white pottery ware.

## 20. CEMENT AND OTHER BUILDING MATERIALS.

C. N. WILEY.

**Double salts of calcium and potassium and their occurrence in leaching cement mill flue dust.** E. ANDERSON. *J. Ind. Eng. Chem.* 11, 327-32(1919).—A. gives a résumé of previous researches on the double salts of K and Ca, *vis.*, potassium mono-, di-, and penta-calcium sulfates. References are given to original articles. Equil. conditions with reference to temp. and concn. are discussed and shown in drawings for  $K_2SO_4$ , syngenite or K mono-Ca sulfate, K penta-Ca sulfate and gypsum. A. finds that the reactions involved in the formation of these double salts are slow, especially in the presence of chlorides. His conclusion regarding the formation of these double salts in the leaching of cement mill flue dust is shown in the following: "Continuous operations have been carried on with practically satd. potash solns., where the time of contact averaged 1 hr., with no sign whatever, either visual or analytical, of the formation of any of the double salts referred to. From the above it will be seen that during the leaching of cement-mill flue dust for the recovery of potash, the operation may be so adjusted as regards time of contact and soln. concn. that the formation of double salts can be avoided at whatever temp. is chosen as being the most desirable for the leaching operation."

O. E. H.

**Compressive strength of cement-lime mortars.** F. A. KIRKPATRICK AND W. B. ORANGE. *J. Am. Ceram. Soc.* 2, 44-64(1919).—Tests were made with one kind only of lime, cement and sand. Hydrated lime added to portland cement mortars in moderate amts. increases d. and strength. Like amts. of cement added to the same mortars cause equal or greater strength increases.

C. H. KERR.

System  $CaO-MgO-SiO_2$  (FERGUSON, MERWIN) 6.

**Treating cements.** W. E. WINDSOR-RICHARDS. Brit. 121,986, Dec. 4, 1917. Clay, preferably dried and powdered, is mixed with ground portland or like cement to form a molding compn. The clay may be china clay, ball clay, or ordinary clay or fireclay. The mixt. may contain asbestos or other fiber. An example is: Portland

cement 30, waste asbestos fiber 15, clay 10. Articles molded from the compn. may be impregnated with a bituminous liquid as described in 3,364, 1915 (C. A. 10, 2137).

**Staining marble.** M. L. McDONOUGH. U. S. 1,293,832, Feb. 11. Marble is heated with steam and is then stained by the use of a soln. prepd. from coal oil, alc. and an aniline dye.

## 21. FUELS, GAS, TAR AND COKE.

J. D. PENNOCK.

**Deterioration in the heating value of coal during storage.** G. CECIL JONES. *J. Soc. Chem. Ind.* 38, 58-9R(1919).—A criticism of the conclusions drawn by Porter and Oritz (C. A. 12, 217). J. calls attention to the necessity of weighing the bulks of coal before and after storage, in order accurately to measure the deterioration. The deterioration measured by P. and O. was only that resulting from the fixation of oxygen, no account being taken of possible loss of coal substance in volatile form. That there was such loss is shown by the increase in % ash upon storage. J. summarizes results from several tables given by P. and O. and adds a column of mean values, from which he draws his conclusions. The results all refer to New River (West Virginia) coal. Even after due allowance is made for sampling and experimental errors, the figures show that the % ash in the coals has increased upon storage, the increase being from 6.8 to 7.5 during the first year, and thereafter at a gradually diminishing rate. If foreign inorg. dust did not gain entrance to the coal heaps, it would appear that about 0.1 the original coal substance had disappeared with the first year, and not much less in the second. The total loss on storage may have been several times as great as P. and O. conclude. J. thinks further expts. are required.

A. G. BLAKELEY.

**Sampling and analyzing coal.** CHARLES BENTLEY. *Pahasapa Quarterly* 8, 55-60(1919).—A brief description of mine sampling and of the usual well-known methods of proximate analysis and heating value detn.

A. G. BLAKELEY.

**Fusibility of coal ash.** W. A. SELVIG, W. C. RATLIFF AND A. C. FIELDNER. *Chem. Met. Eng.* 20, 274-6(1919).—Fusibility tests of ashes of coals from the interior province (including Illinois, Indiana, Kentucky, Missouri, Oklahoma, Arkansas and Texas) are summarized and compared with tests of ashes from West Virginia coals. The tests were made by the gas furnace method (cf. C. A. 13, 372), the ashes being heated in a reducing atm. by which the Fe in the ash was reduced to the ferrous state. This method gives the lowest temp. at which clinkering may result; and this is of special importance in testing ash from coals of the interior province, as these coals contain a relatively large amt. of Fe as pyrite. Analyses of clinkers from boiler furnaces indicated that the conditions were such as to form clinkers in which the Fe is principally ferrous. The tables given include av. values for softening temp., and % ash and S in the dry coals. The point taken as the softening temp. is that at which the ash when molded into solid triangular pyramids 0.75 in. by 0.25 in. wide at the base, and mounted in a vertical position, has fused down to a spherical lump. The softening temp. of coal ash from the various coal fields of the United States ranges from 1900 to 3100° F. The authors subdivide this range into classes: I, refractory ashes, softening above 2600° F.; II, ashes of medium fusibility, softening from 2200 to 2600° F.; III, easily fusible ashes, softening below 2200° F. The W. Va. coals include representatives of all three classes. Ashes of some W. Va. coals did not fuse at 2830° F. in the gas furnace and were heated to 3010° F. in a Mo wire resistance furnace in an atm. of H. Ashes softening above 2830° F. have such a low Fe oxide content that the nature of the atm. surrounding the ash cone has little influence on the fusibility. Ashes from many W.

Va. coals remained unfused at  $3010^{\circ}\text{F}$ . In the case of the province coals, with few exceptions, the av. fusibility values of the different beds are between  $1900$  and  $2200^{\circ}\text{F}$ . The values for different samples in the same mine usually show comparatively small variation, averaging  $140^{\circ}\text{F}$ . The low softening temp. of the ash from the interior province coals is probably due to the pyrite, gypsum, and calcite that occur so generally as impurities in these coals. Individual mines producing lower-S coal than the av. S values given for the bed in which they occur also gave higher fusibility of ash values than that indicated in the table for the bed.

A. G. BLAKELEY.

**Excessive ash in coal.** J. G. WHITE. *Elec. Rly. J.* 52, 504(1918); *Science Abstracts* 21A, 427.—A brief summary of a study made by the J. G. White Engineering Corporation for the U. S. National Research Council of the losses due to high % of ash content in coal. Two charts show the effect of varying % of ash on: (1) heat available for useful work, and (2) coal consumption per boiler horse-power.

E. J. C.

**Western coal.** R. D. MACLAURIN. *Can. Chem. J.* 3, 124-5(1919).—An argument for the use in Western Canada, for domestic purposes, of the Alberta anthracite and especially the bituminous coal and raw lignite instead of imported Pennsylvania anthracite or the proposed manufactured lignite briquets. Lignite, raw, dried, or carbonized, can be burned in a suitable furnace as readily as anthracite; and can be burned without soot, smoke, or danger of explosion. Attention is called to 20-5% waste of fuel due to inefficient methods of combustion.

A. G. BLAKELEY.

**Use of pulverized coal at the Bunker Hill and Sullivan smelting and refining plant.** C. T. RICE. *Eng. Mining J.* 106, 91-4(1918).—An illustrated description of the Holbeck return system for the use of pulverized coal, and the particular application of the method at the Bunker Hill and Sullivan works (Pb smelter), where it is used for boilers, furnaces, and kettles.

F. W. SMITHER.

**Processes of briquetting lignite.** C. DUVAL. *Rev. prod. chim.* 21, 374-6(1918).—A review under the captions: (1) by drying and compression; (2) partial carbonization and compression; (3) by the addition of an agglomerant (various organic and inorganic materials).

F. W. SMITHER.

**Acetylene as fuel for automobiles.** H. GROSSMANN. *Schweiz. Bauzeitung*, Oct. 5, 1918; *Engineering* 106, 469(1918).—The utilization of  $\text{C}_2\text{H}_2$  is of particular importance for Switzerland owing to its manuf. by the aid of hydro-elec. power. The chief difficulties of using  $\text{C}_2\text{H}_2$  fuel in internal-combustion engines are that the compressed  $\text{C}_2\text{H}_2$ -air mixts. are themselves violently explosive, and that the soot and possibly acids produced by the combustion may corrode the motor. The first 2 difficulties can be overcome by diluting the  $\text{C}_2\text{H}_2$  with suitable gases or vapors; the soot deposition can be avoided by providing an ample supply of air. Air might be regarded as the simplest diluent to mitigate the violence of the explosion; G. found, however, that the combustion of air- $\text{C}_2\text{H}_2$  mixts. was always too sudden. The  $\text{C}_2\text{H}_2$  can be generated on board, or it can be taken from steel cylinders containing compressed  $\text{C}_2\text{H}_2$ , dissolved in acetone or in acetone substitutes. Such dissolved  $\text{C}_2\text{H}_2$  is relatively safer than gaseous  $\text{C}_2\text{H}_2$ , (cf. C. A. 12, 1345, 1829). From the cylinder a 2-mm. steel or brass tube is taken to the reducing valve which is connected to the carburetor; no additional app. are required, and the car is always ready for starting and can go on until the cylinder is practically emptied. The disadvantages are that the cylinders are heavy and expensive, and not generally obtainable. Journeys of thousands of km. were made with dissolved  $\text{C}_2\text{H}_2$ , the large cylinders giving a range of 120 km. As regards the generation of  $\text{C}_2\text{H}_2$  from  $\text{CaC}_2$  on the car, although there are hundreds of generators none of those tested by G. proved quite suitable as the  $\text{C}_2\text{H}_2$  has to be purified; the cylinder gas is always pure. The army authorities stipulated that the use of  $\text{C}_2\text{H}_2$  should not involve

any change in the mechanism, and that the machinery should at once be ready for either fuel,  $C_2H_2$  or petrol. Since the  $C_2H_2$  had to be diluted, one complication is unavoidable, whether  $C_2H_2$  gas or dissolved  $C_2H_2$  is to be used; for this purpose an additional tank is provided, and further a set of nozzles by means of which the diluent can be proportioned. A number of diluents appeared serviceable (alc., benzine, petrol, light tar oils, naphthalene,  $H_2O$ , etc.) and at least 20 or 25% of these were required to make the combustion less explosive. In a Martini car of 12 to 16 h. p. the change-over to the  $C_2H_2$  mixt. was effected by substituting a nozzle of 0.50 mm. for the 0.85 mm. nozzle. The % varies with the nature of the diluent; but an experienced driver can soon adjust his motor to the new conditions. Most of the diluents could be used as such; naphthalene and  $H_2O$  required preheating of the carburetor. A mixt. of  $C_2H_2$  with 20% of a mixt. in equal parts of alc. and light tar oil burned very well. Corrosion of the motor was not noted after 2 runs each of 1000 km. (motor fed with dissolved  $C_2H_2$ ). A motor boat was kept running for 6 to 8 hrs. per day for 1 month, the motor was found in good condition, although the  $C_2H_2$  was generated in a common Tozzi app. and not especially purified. The motors did not run hot, except in one case when half of the radiator was covered by an Fe plate. The consumption of lubricant remained normal. As regards fuel consumption, the tests indicate 1 kg. of  $C_2H_2$  is equiv. to about 2.5 kg. of benzine.

F. W. SMYTHES.

Curious coke-heated boiler failure. STROMEYER. *Gas J.* 145, 395(1919).—A coke-fired Galloway boiler developed a peculiar case of external uniform corrosion. On examn. the shell plates were found to be very thin and covered with a scale of dehydrated  $FeSO_4$  and  $Fe_2O_4$ . It was thought that the  $Fe_2O_4$ , being originally in the paint with which the boiler was painted and acting as a catalyst, had converted the  $SO_2$  from the furnace gases into  $SO_3$  which was absorbed by the scale on the boiler plates. It is assumed that when the boiler was lying idle and was cold, the hygroscopic calcined  $FeSO_4$  absorbed from the air enough  $H_2O$  to form with the  $SO_3$  a dilute  $H_2SO_4$ , which in turn acted on the iron and formed continually more  $FeSO_4$  crystals. The suggestion, therefore, is that the elements of  $H_2SO_4$  were formed while the boiler was at work but that the actual corrosion took place only when the boiler was idle.

Present and future of gas: Possibilities of carbonization of all coal at low temperatures. S. W. PARR. *Gas J.* 145, 388-9(1919); *Am. Gas Eng. J.* 110, 66-9(1919).

J. L. W.

Davis "Revergen" principle of firing furnaces with Town's gas. ANON. *Gas World* 70, 189-90(1919); *Gas J.* 145, 385-7(1919).—The "Revergen" principle is described as a "system of town's gas furnace firing by means of which heat losses by way of the furnace flue are reduced to an insignificant minimum and the thermal energy thus recovered utilized almost exclusively for the practical purpose of the furnace." The principle is one of "reversible regeneration" by means of which the air is heated on its way to the furnace. The gas and air, the latter at a pressure of a few inches water gage, are introduced separately each under the individual control of a main supply valve, and provided with means for accurate adjustment. Double recuperators, built under the oven, are of the exact capacity to extract the max. amt. of heat from the escaping gases and transfer it to the incoming air. Owing to the scarcity of essential highly refractory materials for construction of furnaces, the possibilities have not been fully exploited, although temps. of  $2000^\circ$  have been attained. One furnace with gas flow rates of 370, 600, and 800 cu. ft. per hr. recorded, resp., oven temps. of 1050, 1300,  $1360^\circ$  and gas flue temps. of 65, 105,  $182^\circ$ . A special test on a "Revergen" furnace and one of the best types of competitive furnaces was made. The test required that the oven be brought to  $820^\circ$  and loaded with billets, the whole being then brought back to the same temp. and maintained for 1 hr. The gas consumption per lb. of charge

for raising the temp. to  $820^{\circ}$  in the "Revergen" was 1.3 cu. ft., efficiency gain 48%; in the competitive furnace 2.5 cu. ft., efficiency loss 92.3%; maintaining the charge at  $820^{\circ}$  in the former for 1 hr. was 0.341 cu. ft. or 36% gain; in the latter 0.534 cu. ft. or 56% loss. Inclusive calcn. per ton of billets heated showed an efficiency gain of 46% for the "Revergen" and 84% loss for the competitive furnace. In computing the % of loss, the "Revergen" consumption figure was taken at 100, and the same value given to the competitive consumption in arriving at the % of gain in favor of the "Revergen." Several of these furnaces are in daily use and show fuel economies varying from 33 to 50% as compared with former costs.

*Iron Coal Trades Review* 98, 323(1919).—Further tests of the "Revergen" furnace with a  $54 \times 32 \times 24$  inch furnace: (1) 985 lbs. billets were charged into the furnace and heated to and kept at  $1000^{\circ}$ ; the time taken was 1 hr. 15 min. and the gas consumed per lb. of charge 1.421 cu. ft.; (2) 980 lbs. under similar conditions of time and temp. consumed 1.6 cu. ft. of gas per lb.; (3) 987 lbs. under same conditions consumed 1.59 cu. ft. of gas per lb. The billets when drawn had a temp. of  $1020$  to  $1025^{\circ}$ ; the av. exhaust gas temp. was  $180^{\circ}$  F. and at no time was that temp. in excess of  $200^{\circ}$  F. The av. calorific value of the gas used was 463 B. t. u. J. L. WILEY.

**New design of vertical retorts: The central system.** ANON. *Gas J.* 145, 455-6 (1919).—The system is of the semi-continuous, regenerative type and employs a minimum of labor, all operation being centrally controlled. It is compact in structure, the retort house being of octagonal shape, the alternate sides having 4 retorts, the triangular spaces between the retorts containing the producers and regenerators. Each bed of retorts is connected by a sep. flue to a central chimney and is separately controlled. The charging is done by means of a radial chute extending from the center and revolving on a track over the top of the hoppers. It is claimed to be a decided improvement over existing types for convenience and celerity of operations. J. L. WILEY.

**Improvements in carbonizing apparatus.** NORTON H. HUMPHREYS. *Gas J.* 145, 321-2(1919).—The objects of the inventions described are the prevention or the diminution of the formation or accumulation of carbonaceous or viscid deposits in the retort or the outlet therefrom; improved results both as to quantity and quality of the products; a combination of the advantages peculiar to the dry main and hydraulic main; and facilitation of the working of twin or coupled retorts. These results are accomplished by dividing the hydraulic main into compartments, one for each ascension pipe, and flooding any or all of these compartments whenever a seal is desired or for the purpose of washing out accumulations of pitchy matter. Means are also provided for reducing oscillation of pressure when working under seal. J. L. WILEY.

**Secondary reactions of oxide of iron purification.** G. WEYMAN. *Gas J.* 145, 322-3(1919).—The effect of the decompn. of steam by the S vapor under the high temp. developed is shown by the equation  $2S + 2H_2O = H_2S + SO_2$ . To prevent this reaction in the oxide purifier, the temp. of the last box should be kept fairly low, and no extra steam admitted. J. L. WILEY.

**Low-temperature carbonization in relation to the production of motor spirit, fuel oils, smokeless fuel and power gas: its aims and objectives.** F. D. MARSHALL. *Gas J.* 145, 383-5, 451-4(1919).—M. proposes to reduce the abnormal waste in utilizing fuel by subjecting it to the following cycle of operations: (1) Carbonization of the raw coal at a low temp. and recovery of the liquid products and a portion of the  $NH_3$ ; (2) gasification of the resultant coke into producer gas with recovery of the bulk of the  $NH_3$ ; each ton of coke will yield 120,000-140,000 cu. ft. of gas with a calorific value of 120-130 B. t. u. per cu. ft.; (3) conversion of the power gas into electricity; 110 cu. ft. of 130 B. t. u. gas will develop in good engines 1 kw. hr., and if for raising steam, 200

cu. ft. will develop 1 kw. hr. in efficient steam turbines. An av. coal when submitted to a high temp. in the retorts of 2000–2200° F. will yield approx. per ton: gas 12,000–13,000 cu. ft. of approx. 500 B. t. u., coke 66%, tar 9–10 gals.,  $(\text{NH}_4)_2\text{SO}_4$  20–28 lbs.; to a low temp. of 900–1200° F.: gas 4000–6000 cu. ft. of approx. 650 B. t. u., coke 70–75%, tar oils 18–22 gals., sulfate 15–22 lbs. Solid, compact and transportable low-temp. coke can be produced by confining the coal in comparatively narrow chambers with walls sufficiently strong to withstand the pressure of expansion of the coke. Under the low temp., a swelling coke will reach its max. of expansion in about 3.5 hrs. and will then shrink to allow of easy discharge. Such coke will also contain a residue of 9–12% of volatile matter which makes it easily ignitable and satisfactory for fuel. Its calorific value compared with good coal is 13,300 B. t. u., coal being 14,200 B. t. u. Low-temp. gas varies in thermal value from 550 to 650 B. t. u. before washing, after washing 400–450 B. t. u. Low-temp. carbonization of an ordinary bituminous coal gave results per ton as follows: Coke 75% containing 9% inflammable gas, very hard and dense; crude oils, water free 22 gals, sp. gr. 1.06; ammoniacal liquor, 9.5%; motor spirit, 3.94 gals.; pitch, 23%; ash in coke, 10.3%. Cannel coal gave results as follows: Coke, 70%, poor for domestic purposes but good for producer gas; ash in coke, 20.4%; crude oils, 53.5 gals.; ammoniacal liquor, 0.5%; pitch, 29%; motor spirit, 8.75 gals. The process described is the Tozer process, originally devised by the Tarless Fuel Syndicate. It consists in distributing the coal in thin layers in the form of a circle in such a way that a charge of 20–25 cwt. of coal can be carbonized in 4.5 hrs. The retort is constructed with 2 annular sections, one disposed concentrically within the other, the exterior heat being conducted through the first annulus of coal to the second by ribs which divide the annuli into vertical cells, advantage being taken of the conductivity of the cast iron of which the retort is built. The inner tube formed by the surrounding annuli is not filled with coal, but acts as a gas passage connecting the upper and lower ends of the retort. The retort will deal with practically every kind of carbonaceous material, caking and non-caking coals, shales, lignites and peat, in every physical condition from 3-in. down to dust, and will carbonize and produce coke from colliery slack and washings. The retorts are heated by a specially designed recuperative setting.

J. L. WILEY.

**Determination of gasoline in gas.** W. P. DYKEMA AND R. O. NEAL. *Chem. Eng.* 27, 5–7(1919).—The only accurate method of detg. the gasoline content of gases that contain less than a gal. of gasoline per 1000 cu. ft., is to allow a given quantity of the gas to come into contact with some absorption medium and to sep. the absorbed gasoline by distn. The app. (see fig.) consists of a piece of 6-in. casing with 5 sep. compartments, each of which is connected with  $\frac{3}{8}$ -in. gas inlet and also with a 2-in. gas discharge pipe or sep. chamber which extends to a point near the bottom of the casing. From the casing runs a  $\frac{3}{8}$ -in. pipe coiled around a 3-in. core with 7 turns, through which the gas being treated bubbles and in which most of the absorption takes place. There are valves at each extremity of the app. in order that gas may not be introduced too rapidly or may be throttled to any desired pressure so as not to carry oil over from one compartment to the next, also the use of a needle valve on discharge end to enable one to regulate more easily the rate of flow through the meter, especially in tests at low pressures, *i. e.*, when the gas flows through the absorber very slowly. It is advantageous to use gate valves instead of drain cocks for drawing off treated absorption oil from the oil chambers, as such valves facilitate rapid work and eliminate the possibility of volatilization losses when oil is allowed to spray through a stopcock under pressure, into the container for collecting treated oil. Also, time can be saved by using small bull-plugged nipples, in place of standard plugs, as they can be more easily removed and more rigidly connected to prevent leaks. To make the test, 2700 cc. of mineral Seal

Oil, or enough to bring the level of the oil about 2 in. above the top of the 6-in. casing and well above the coil inlet, is accurately measured and introduced into each compartment. The most important requisite for absorption media is high initial b. p. In most tests only the first 3 absorbers are used but it may be expedient to fill the 4th compartment when examining rich gases at low pressures or when running a large vol. of dry gas. The 5th division serves as an oil trap. A meter capable of measuring from 1 to 1000 cu. ft. of gas accurately is connected to the discharge of the absorber. The gas entering the absorber bubbles up through the oil, the latter absorbing the gasoline. After the desired amt. of gas has passed through the absorber the supply is shut off and the pressure is released, through the needle discharge valve, allowing all the gas to flow through the meter. After the pressure has decreased to atm. pressure, all of the oil is withdrawn at the bottom of the casing and the oil from each compartment is accurately measured, 1000 cc. of treated oil from each compartment being kept for distn.

Introduce 400 cc. of the treated oil into a 500-cc. Engler distilling flask connected to a condenser made of  $\frac{1}{2}$ -in. brass tubing and surrounded by ice  $H_2O$  contained in a metal box. The flask is heated by direct fire, slowly at first, and the gasoline is collected in a graduated cylinder. The flask is heated until the vapor reaches a temp. of  $177^\circ$  (usually requires about 20 min.). If the oil has a very high satn., let cool to 20 or  $30^\circ$  and again raise to  $177^\circ$ . This procedure is followed until practically no more gasoline is driven over and collected from the condenser. From the gasoline recovered from 400 cc. of oil from each compartment, calculate the vol. of gasoline in the total vol. of oil as measured. Gasoline content of the gas is calcd. by the formula  $G = (1000/V)(C/3785)$ , where  $G$  = gasoline content in gals. per 1000 cu. ft. of gas,  $V$  = the vol. in cu. ft. of gas treated, and  $C$  = the total no. of cc. of gasoline obtained from the treated absorption medium. The extn. of gasoline by the oil will depend upon the rate

of flow, gasoline content of the gas, vol. of gas treated, pressure, and the temp. of the absorbing oil. Optimum conditions as regards vols. of gas and rate of flow with gases at different pressures and gasoline content are given in a table. Data are given from tests made at a compression plant.

F. W. SMITHER.

**Experiments with bituminous coal in the manufacture of water gas.** R. G. KRUMREY. *Am. Gas Eng. J.* 110, 291-2(1919); *Gas Record* 15, 217-220(1919).—Operation of water-gas plant at Beloit, Wis., with coal is described. Av. operating results for 1 yr. with coke and coal, resp., are: cu. ft. of air per min. per sq. ft. of grate 150 and 100, cu. ft. of air per 1000 cu. ft. of gas 1490 and 1155, blast pressure 18 to 20 and 16 to 24 inches, steam per min. per sq. ft. of grate up run 1.75 and 2.06 lb., down run 2.15 and 2.3 lb., steam per 1000 cu. ft. gas 33 and 42.5 lb., av. running time 11 and 18 hrs., cu. ft. gas made per run per sq. ft. grate 288 and 228, gas per hr. per sq. ft. grate 2016 and 1596, generator fuel per 1000 cu. ft. gas 36.7 and 45.9 lb., oil used per 1000 cu. ft. gas 3.58 and 3.28 gal., B. t. u. 600 and 600. The saving in cost of coal over coke operation was \$0.116 per 1000 cu. ft. of gas made. During the last month certain slight changes in air and steam consumption were made by which the make was increased 140 cu. ft. and the oil and fuel were decreased, resp., 0.06 gal. and 2.5 lb. per 1000 cu. ft. of gas.

J. L. WILBY.

**Water-gas operating methods with central district bituminous coals as generator fuel.** W. A. DUNKLEY AND W. W. ODELL. Ill. State Geol. Survey, *Bull.* 24, 24 pp. (1919).—A preliminary paper giving some suggestions for operating with coal in water-gas plants. The actual results obtained and the details of operation, including chem. data, will be published later.

J. L. WILBY.

**Calorific value of New Zealand gas.** ANON. *Gas J.* 145, 587(1919).—A minimum of 500 B. t. u. net is proposed.

J. L. W.

**Bearing of Prof. V. B. Lewes work on today's carbonizing developments.** C. B. TULLY. *Gas J.* 145, 515(1919).—In his book "Liquid and Gaseous Fuels," Prof. Lewes argues against steaming of retorts on the ground that, due to generation of CO<sub>2</sub>, it is detrimental to the illuminating and thermal efficiency of the gas and is economically bad, having nothing whatever to recommend it. He advises the use of water gas as a diluent, saying that it will produce the cheapest B. t. u. obtainable, at the lowest possible capital outlay and costing not more than 0.4 d. per 1000 cu. ft. for repairs and maintenance of plant.

J. L. WILBY.

**Dehydration of various tars.** W. A. TWINE. *Gas J.* 145, 462-4(1919); *Gas World* 70, 149-50(1919).—Two methods are described. In the first method, tar containing 25-40% H<sub>2</sub>O is preheated in an ordinary boiler shell fitted with steam coils where the H<sub>2</sub>O content is reduced to about 7.5%. It is then run intermittently in charges of 120 gals. every hr. for 6 hrs. into a tar dehydrator consisting of an inverted cone fitted with a helical channel and working under a vacuum of 25 in. of Hg. Distn. is continued with continuous firing until the pitch is reduced to the correct m. p. In the second method, water-gas emulsion containing 45-75% H<sub>2</sub>O is treated in stills of the Hird, Hammond and Chambers type. The emulsion is preheated to an inlet feed temp. of 95-98° by passing through the waste gas flue in a 3-in. pipe. Successful working depends upon (1) constant H<sub>2</sub>O content of the emulsion, (2) regular feed to the still, (3) constant temp. of the feed, (4) regular firing. The H<sub>2</sub>O content of the tar is reduced to below 0.5%. The plant can dehydrate about 15 tons of 50% emulsion per 24 hrs.

**Importance of by-products during the war.** C. G. ARWATER. *Gas Age* 43, 339-43 (1919).

J. L. W.

**All-new water gas plant results at Providence.** WALTER RUSSELL. *Gas Age* 43, 277-82, 364-6(1919).—Full description of the plant is given and operating methods are discussed. With 3 U. G. I. standard water-gas machines, guaranteed to produce 3.5 million cu. ft. of gas per 24 hrs. yields from 16600 to 22200 cu. ft. of gas per run of 4 mins. were obtained. An av. of 37.3 lbs. of fuel were required per 1000 cu. ft. of gas. Both anthracite coal and coke were used of an av. analysis, resp., of:  $H_2O$  2.94 and 10.12, volatile matter 6.86 and 4.19, fixed C 73.70 and 73.77, ash 16.50 and 11.92. The av. consumption of oil per 1000 cu. ft. of gas for the yr. was 3.39 gal., with a residue of 23%, paraffin 74.5%, B. t. u. per gal. 105, B. t. u. of gas 589.

J. L. WILEY.

**Why American coke oven practice leads the way.** RICHARD GUNDERSON. *Gas World* 70, No. 1806 (Coking & By-products Sec.), 12-4(1919).—Three factors have contributed toward making the American by-product coking industry vastly more efficient than that of any other country: (1) application of science and research work in the industry; (2) location of coking plants at the steel works; (3) unity of control. (Also in *Gas Age* 43, 407-11(1919).)

J. L. WILEY.

**By-product (coke) plant of the Brier Hill Steel Co.** F. T. MORGAN. *Gas Age* 43, 351-3(1919).—An illustrated descriptive article.

**Fuel composition.** RICHARD F. DALTON. *Can.* 189,256, Mar. 25, 1919. One ton of coal dust or screenings is mixed with approx. 10 gal. of water-gas tar.

**Natural gas substitutes.** C. S. PALMER. *Can.* 189,403, Apr. 1, 1919. Fuel is heated in a chamber having thin nichrome walls by a highly heated gaseous medium without the direct introduction to the chamber of substantial quantities of air blast and simultaneously supplying highly superheated steam to effect the water gas reactions in the charge so as to produce a strongly reducing highly heated gaseous medium in contact with a substantial portion of the inner surface of the chamber. App. is also specified.

**Treatment of gases obtained from coal and other carbonaceous fuel.** E. V. ESPENHAHN. *Can.* 189,364, Apr. 1, 1919. Gases are purified by treating them at a temp. about their dew point with a concd. soln. of  $Na_4Fe(CN)_6$ . The concd. alkali soln. at the beginning of the operation has the Fe in suspension as the sulfide. The  $Na_4Fe(CN)_6$  may be used repeatedly.

**Gas producer.** W. D. TURNER. *Can.* 189,668, Apr. 15, 1919. The generator chamber has a hollow ring of fire brick built in as part of the furnace wall above the fire bars and provided at its inner wall with gas inlets and in its outer wall with gas outlets. The generator also has downwardly movable hinge doors having spring-controlled, pivoted arms associated with the under sides thereof for closing them.

Combustible liquid for illuminating purposes. A. S. LARSEN. Dan. 23,469, Sept. 2, 1918. Denatured alc. 60, crude benzene 15, and turpentine 25 are mixed for use as an illuminating liquid.

Coking apparatus. F. J. SIVYER. Can. 189,418, Apr. 1, 1919. Structure.

## 22. PETROLEUM, ASPHALT AND WOOD PRODUCTS.

F. M. ROGERS.

Gasoline standardization in states. G. W. GRAY. *Oil & Gas J.* 17, No. 41, 64-5 (1919).—The specifications for gasoline and kerosene in various states are given. The extreme variation is cited as showing the need of standardization of specifications.

R. R. MATTHEWS.

Still's important parts of refinery. W. F. STATHAM. *Oil & Gas J.* 17, No. 41, 58(1919).—The different products obtained from the various stills are shown starting with the crude still, or "pipe still." The combination still is now used in place of the straight steam still, it can be fired if desired and does not depend on steam alone for fractionation. Re-run stills for fractionating kerosene distillate are also combination stills. Tar stills are necessary where lubricating oils and paraffin are produced.

R. R. MATTHEWS.

Loss of petroleum by evaporation. J. H. WIGGINS. *Oil & Gas J.* 17, No. 42, 51(1919).—Most of the evapn. occurs in flow tanks and lease storage. Approx. 3 to 4% is lost during the first six months. Oil is generally held 4 to 6 months before being refined, which makes the loss an enormous figure. The tank with water seal top, sprinkling the roofs and protecting by lagging have all been used but no data are available showing their relative value. The present plan is to have about 10 of the largest companies share in field expts. and allow the Bureau of Mines to publish the results.

R. R. MATTHEWS.

"Degree of mercuration" of crude petroleum oils and their products for the control of refinery processes. J. TAUSZ. *Petroleum* 13, 649-54(1918); *J. Soc. Chem. Ind.* 38, 4A(1919).—A soln. of  $\text{Hg}(\text{OAc})_2$  in MeOH is shaken with the oil sample. Liberated AcOH is titrated with KOH soln. The number of cc. of *N* KOH required to neutralize the AcOH liberated by 100 cc. of oil is called the "degree of mercuration." The undesirable constituents, such as unsatd. hydrocarbons, S compds., asphaltic and resinous compds. and phenols, react with the acetate, forming Hg compds. and AcOH.

W. F. FARAGHER.

The viscosity of lubricating oils. E. ORLSCHLÄGER. *Z. ver. deut. Ing.* 62, 422-7 (1918); *Science Abstracts* 21B, 320-1.—O. in this portion of his extended series of articles upon lubricating oils, deals with the relation between viscosity and temp. He points out that it is customary to carry out the viscosity test at various temps. according to the intended application of the oil, the usual test temp. for transformer oils being 20°, for bearing oils at 50°, and for cylinder oils 100°. No formula or chart, however, has existed up to the present which would enable one to calculate the viscosity at any other temp. than that at which the observation was actually made. As a result of an extended investigation of the results obtained with many oils, O. has constructed curve diagrams which overcome this difficulty. By aid of these, the viscosity of any oil can be ascertained for any temp. when one detn. of it has been made. The only exceptions to the law governing the rate of change in the viscosity, with temp. variations, are: rape-seed oil, linseed oil, and blubber oil.

Determination of gasoline in gas (DYKEMA, NEAL) 21. Lubrication of air compressors (CONRAD) 18.

Distilling petroleum oils. A. F. G. P. J. VON GROELING. U. S. 1,295,088, Feb. 18. Crude oil is distd. by heating a portion of the oil under pressure, reducing the pressure on the oil and introducing into a still containing a portion of the oil to be distd., so that the latter is vaporized upon reduction of pressure and distn. is thus effected.

Lubricating grease. F. B. MASON. U. S. 1,294,136, Feb. 11. Crude commercial fatty acids are quickly heated with a heavy mineral oil to a temp. above 100° and the free fatty acids present are neutralized by the addition of dry  $\text{Ca}(\text{OH})_2$ . After heating for about half an hr. the neutralization is completed and most of the  $\text{H}_2\text{O}$  formed is evapd. A lubricant of the desired consistency is then formed from the product by thinning it as desired with mineral oil and a small amt. of  $\text{H}_2\text{O}$  is added to form an emulsion between the oil and soap. A similar product is also obtained if the entire quantity of oil used is added at the first of the process.

Coking crude-oil residuum. T. E. MURRAY and E. B. RICKERTS. U. S. 1,293,866, Feb. 11. Residuum from crude oil is coked by the action of hot gases in contact with it as it flows in a thin film over the inner surface of the coking chamber.

Turpentine-still. G. BURTON. U. S. 1,293,027, Feb. 4.

Subdividing asphalt, pitch or similar material centrifugally. K. B. HOWELL. U. S. 1,294,909, Feb. 18. Pitch, asphalt or similar material in molten condition is divided into a number of sheets by the action of a centrifugal app. which projects the sheets in divergent directions at different speeds into a cooling medium such as air in which powdered talc may be suspended to render the product non-adhesive.

Recovering fiber and asphalt from roofing scrap. B. A. ALLISON. U. S. 1,293,293, Feb. 4. Roofing scrap containing asphalt and fibrous material is boiled in an alk. soln., e. g., a 5% alkali soln., and the disintegrated mass of fibrous and asphalt material is removed and rolled into sheets, which are adapted for use as a heat-insulating or roofing material. Additional asphalt may be added before rolling.

## 23. CELLULOSE AND PAPER.

A. D. LITTLE.

The paper industry in Japan. ANON. *Daily Consular and Trade Reports*, U. S. Dept. of Commerce 82, 164-77(1919).—A description is given of the present status of the paper industry in Japan. Statistics on production, prices, and grades are given.

R. B. ROE.

Detection of soda and sulfite wood pulps in paper. R. WASICKY. *Papier fabr.* 16, 212-3, 228-9; *J. Soc. Chem. Ind.* 38, 131A(1919).—The sample is boiled with a 0.2% soln. of Gentian Violet, allowed to remain 2 min., rinsed with 95% EtOH, and immersed for 2 min. in 95% EtOH containing 0.5% HCl. It is washed for 15 min. in 95% EtOH renewing the latter once, and finally in  $\text{H}_2\text{O}$ . Pure soda-pulp papers lose the color entirely, while sulfite papers are stained a deep violet. By the use of known standards, the method is accurate to about 5%.

R. B. ROE.

**Nature of the cellulose of cereal straw. II.** E. HEUSER AND A. HAUG. *Z. angew. Chem.* 31, 166-8, 172-6; *J. Soc. Chem. Ind.* 37, 650-1A.—The crude cellulose prep'd. by the chlorination method with NaOH (cf. *C. A.* 12, 2439), contained 0.35% ash, while that prep'd. with  $\text{Na}_2\text{SO}_3$  contained 1.1%. The yield of crude cellulose was 54.60% with a furfural value of 13.30%, equiv. to 22.34% xylan. The calcd. yield of true cellulose was 42.97%. The original straw had a furfural value of 15.4, equiv. to 25.62% xylan on the dry ash-free basis; thus 47.32% of the original xylan remained in the cellulose. The proportion of xylan remaining in the cellulose varies inversely as the yield of cellulose, and is a function of the concn. of NaOH used for extg. the chlorination products. The furfural value of com. straw cellulose varies with the yield and severity of chem. treatment; it may reach 18%. Most of the xylan may be removed from crude straw cellulose by repeated extns. with 6% NaOH, but it has not been possible to reduce the furfural value below 1.95% in this way. Commercial bleached straw cellulose shows a Cu value of 3.0, unbleached straw cellulose 0.94-0.99, and the bleached cellulose after extg. until the furfural value reaches the limiting 2.0%, shows a Cu value of 0.61-0.78. Further bleaching may increase the Cu value to 15.5 without affecting the furfural value. Hence straw cellulose does not correspond to a special type of natural oxycellulose, but is an ordinary cellulose similar to that of cotton or wood, strongly contaminated with a pentosan and so modified by bleaching under industrial conditions, that the pulp contains a substantial amt. of oxycellulose. Further examn. to account for the residual 2% of furfural, indicates that this residue consists of a trace of xylan, equiv. to less than 1% furfural, which is obstinately retained by the cellulose, while 1.0-1.5% of furfural may be attributed to the cellulose itself as in the case of cotton cellulose. Hydrolysis with  $\text{H}_2\text{SO}_4$  resulted in a practically complete reduction to dextrose, and the constitution of straw cellulose apparently corresponds to that of cotton cellulose.

R. B. ROG.

**Clays for use in paper making.** RALPH B. ROG. *J. Am. Ceram. Soc.* 2, 69-73 (1919).—The important points are color, grit and retention. Color is compared directly with the standard white sample. Grit is det'd. by wet sieving through 200-mesh sieve. The best clays show not over 0.20% residue and many show under 0.10%. Retention is the ratio of the amt. retained in the paper to the amt. added. There is no satisfactory lab. test. Domestic clays are being increasingly used. C. H. KERR.

**Mechanical woodpulp.** P. ROCHON. *Le papier* 21, Nos. 10, 11(1918); 22, No. 1 (1919).—The author describes in these 3 articles the general processes of the manuf. of mechanical wood pulp. He describes horizontal and vertical grinders, and the *Voith magazine grinder*, and discusses the conditions which ensure the best results. He takes up screening and refining, giving detailed descriptions of both flat and centrifugal screens and of their action. He describes also the principle and the action of the deckers, save-all, and wet-machine, including the wet-machine with several vats. After enumerating the uses and properties of white groundwood, he concludes with a description of the process of making "brown" pulp, which consists essentially in steaming the wood before grinding.

A. P.-C.

**Pulp from waste wood.** C. FLAUNET. *Le papier* 22, No. 1, 23(1919).—The following process, which is applicable to such waste as edgings and saw-dust, is due to Messrs. Brech and Tylorowski, and is being used by the Rosenblum Company. The wood is introduced into a vessel, and a "solution" of resin solvents in water is added. The amt. of solvent should be 1.5-2% of the wood, more or less, and about 1% of ammonia is also added. The solvent should be of such a nature as to emulsify with water. The wood is cooked for 4-5 hours at 110°. When all the resin has been extd. the vessel is opened at the bottom when under a pressure of about one atm., thereby ejecting the liquid and vapor but leaving the wood. By adding lime before extg. the resins,

a lime soap is formed, the recovery of the ammonia is greatly facilitated, and the treated wood is lighter in color. The wood is then steamed, which obviates the necessity of chipping. It is then made into pulp by the sulfite process. A. P.-C.

**Eucalyptus as a source of paper.** J. MICOL DE PORTEMONT. *Le papier* 22, No. 1, 17(1919).—Eucalyptus yields about 42% of cellulose fibers. The fibers are rather short (about 0.9 mm.) but extremely fine (about  $16\mu$  in diameter), and consequently they felt very well, and they are also very strong. The tree possesses the advantage of a remarkably rapid growth, a growth of 20 years yielding about 1000 steres per hectare, while it is but very rarely that 500 steres are obtained from other species of 75 years' growth. The author suggests establishing eucalyptus forests in the swampy regions of Southern France, thereby creating an important source of wealth for the country and at the same time changing an unhealthy swamp into a healthy and habitable region. A. P.-C.

**Paper soles.** *Le papier* 21, 11, Nov. 1919, p. 190.—About 30 sheets of paper are first soaked in turpentine, and then treated with a glue made up of turpentine, Spanish white, resin lac, linseed oil and litharge. The compn. is then submitted to high pressure. After scraping and polishing it will furnish soles as waterproof and as durable as the best of leathers. A. P.-C.

#### Progress of paper textiles in the United States (Brock) 25.

---

**Recovering solvents from colloided nitrocellulose.** W. F. NASH. U. S. 1,293,515, Feb. 4. The excess of alc. and ether present in colloided nitrocellulose is removed by first displacing the contained ether with alc. and then displacing the contained alc. by means of  $H_2O$ .

**Cellulose manufacture.** E. SCHAUFFELBERGER. Can. 187,949, Dec. 17, 1918. A combination of app. used in making cellulose is described.

**Pulp and paper from garbage.** J. F. PUTTAERT and H. F. J. PUTTAERT. U. S. 1,294,163, Feb. 11. Cardboard is formed from garbage by first removing hard substances from it, crushing the remainder and reducing its moisture content to below 50%, then expressing a further portion of  $H_2O$ , extg. grease, working up the pulp with alkalies or other reagents, beating it and forming it into sheets.

**Stencil-paper.** E. THOMAS. U. S. 1,293,983, Feb. 11. A mixt. formed of ceresin 100, Al oleate 12 and wool wax 4 parts is used for coating Yoshino paper to form stencil sheets. The Al oleate gives the sheets great flexibility. Adhesion of the sheets, one to another, may be avoided by the use of a thin auxiliary coating of stearic acid.

---

## 24. EXPLOSIVES AND EXPLOSIONS.

---

CHARLES E. MUNROE.

**Glyceryl methyl ether dinitrates ( $\alpha$ -methylin dinitrate).** DAVID TREVOR JONES. *J. Chem. Soc.* 115, 76-81(1919).—The nitration of Grün and Bockish's glyceryl  $\alpha$ -mono-methyl ether with mixed acids between  $13^\circ$  and  $20^\circ$  for 20-25 min. gave a product completely sol. in the nitrating acids, but largely pptd. on diln., a remainder being extd. with  $Et_2O$ , giving a total yield of 77% theory, as a clear, colorless liquid  $b_{18} 124^\circ$ , approx. the same as the ether from which it was derived and  $22^\circ$  lower than  $C_6H_5OH(NO_2)_2$ . It crystallizes with difficulty to white monoclinic prisms, m.  $24^\circ$ , for which no labile modification was found. They were quite insensitive to friction, but on heating at a rate of  $5^\circ$  rise per min. exploded at  $182^\circ$ ;  $C_6H_5(NO_2)_2$  exploded at  $192^\circ$ . The liquid at

100° was 7-8 times more volatile than  $C_6H_5(NO_2)_3$ ,  $d_{15}^{15}$  1.374,  $n_D^{21}$  1.4478. It is sol. in many org. solvents but insol. in  $CS_2$  and light petroleum. It gelatinizes nitrocotton rapidly and after warming yields a softer and more plastic gelatin than  $C_6H_5(NO_2)_3$  does. Its explosive power is about  $\frac{2}{3}$  that of  $C_6H_5(NO_2)_3$ , but it is much less sensitive to shock. 75% kieselguhr dynamites made with each gave with a 1-kg. fall hammer 10 explosions in 10 falls of 20 cm. with nitroglycerin and but 2 explosions in 10 falls of 100 cm. with the dinitrate. In Trauzl blocks with these dynamites for equal charges nitroglycerin gave a 30-cc. and the dinitrate 22.9 cc. cavity. In the ballistic pendulum nitroglycerin dynamite gave 124.43 kg. and the dinitrate 93.76. The mol. f.-p. depression const. of  $C_6H_5(NO_2)_3$  with the dinitrate was found to vary from 72.4 to 81, which differed little from those heretofore found for  $EtNO_2$  and  $C_6H_5Cl(NO_2)_2$ . CHAS. E. MUNROE.

**The propagation of flame through tubes of small diameter.** WILLIAM PAYMAN AND RICHARD VERNON WHEELER. *J. Chem. Soc.* 115, 36-45(1919); cf. *C. A.* 12, 2276.—It is common practice to test miners' safety lamps by introducing them into an inflammable mixt. of coal gas and air. The speed of propagation of flame in this mixt. can be considerably faster than in any mixt. of  $CH_4$  and air and since any inflammable mixt. into which a miner's lamp may in coal mining be accidentally introduced will be a mixt. of air with marsh gas, which but rarely contains even traces of other inflammable gas besides  $CH_4$ , the use of coal-gas-air mixts. for such testing is justifiable only on the grounds of providing an adequate "margin of safety." This becomes unjustifiable if the "margin of safety" is excessive, for every additional protective device embodied in the construction of a miner's flame safety lamp militates against the proper ventilation of the lamp, and diminishes its light-giving power. It was therefore deemed important to make exact comparison of the speeds of propagation of flame in the two different mixts. under similar conditions of expt. and to obtain information on the effect of varying the proportions of the constituents in coal-gas on the speed of propagation of flame in their mixts. with air. The general conclusion to be drawn from these expts. is that "coal-gas" is an unsuitable gas to employ in testing miners' safety lamps for the following reasons: (1) Comparatively small variations in the compn. of coal-gas affect the speed at which flame can travel in its mixts. with air. In particular, a reduction in the proportion of paraffins which it contains, such as is usually accompanied by an increase in the proportion of H when, as generally, carbureted water-gas is employed to dil. the coal-gas, enables a much higher speed of flame to be attained than can be given by mixts. of  $CH_4$  and air. (2) Even with gas produced solely by the carbonization of coal at normal retort temps., the speed of propagation of flame attainable is more than double that possible in mixts. of  $CH_4$  and air. (3) It would seem that the ability of flame to pass through tubes or holes of small diam. is not dependent alone on its speed, although this is the main factor, but is to a certain extent a quality of the inflammable gas concerned. Flame in mixts. of H and air possesses the property of being able to pass through holes of very small diam., and the presence of H in coal-gas confers this property in a certain degree on the flame in mixts. of the latter with air. In tests of various coal-gas—air mixts. and  $CH_4$ —H—air mixts. it was found that the distance the flame was propagated diminished with the diminution of the diam. of the tube until when a diam. of 2 mm. was reached the propagation was *nil*. Mallard and Le Chatelier recorded for a H (30%) air mixt. a propagation in a glass tube of but 0.9 mm. diam. CHARLES E. MUNROE.

**The dilution limits of inflammability of gaseous mixtures.** III. The lower limits of some mixed inflammable gases with air. IV. The upper limits of some gases, single and mixed in air. HUBERT FRANK COWARD, CHARLES WILLIAM CARPENTER AND WILLIAM PAYMAN. *J. Chem. Soc.* 115, 27-36(1919); cf. *C. A.* 8, 2806, 3364.—The conclusions from the exptl. observations cited are for Part III. The lower limits of

inflammability, in air, of mixts. of H, CO, and  $\text{CH}_4$ , taken two at a time or all together, and also the lower limits of water gas, coal gas, and town's gas, may be calcd. with approximate accuracy from the lower limits of the individual gases by means of Le Chatelier's formula; and for Part IV: The upper limits of inflammability in air, satd. with water at 18-19°, of H,  $\text{CH}_4$ , and CO are in the neighborhood of 74.2, 15.4 and 74.2%, resp. The upper limits in air of mixts. of these gases, taken 2 or 3 at a time, and also the upper limit of coal gas, may be calcd. with approximate accuracy by means of a simple formula of an additive character. The photographs of the flames produced in long tubes are unique, that of H being a faintly luminous segment of a hollow sphere; that of  $\text{CH}_4$  a segment like that for H, colored blue, with reddish brown conical tail, that of CO shaped like a Welsbach mantle colored blue with a bright whitish blue edging; and that for a  $\text{CH}_4 + \text{CO}$  mixt. being a composite of the two latter figures.

CHARLES E. MUNROE.

**Application of nitro-aromatic compounds in explosives industry.** J. R. MARDICK. *Chem. Met. Eng.* 21, 311(1919).—The use is advocated of TNT and  $\text{C}_6\text{H}_5(\text{NO}_2)_3\text{OH}$  in the manuf. of commercial blasting explosives. They may now be produced at 10 and 12 c. per lb., resp., from  $\text{C}_7\text{H}_8$  at 18 c. per gal. and  $\text{C}_6\text{H}_5\text{OH}$  at 6 c. per lb.

CHARLES E. MUNROE.

**The ignition of explosive gases by electric sparks.** JOHN DAVID MORGAN. *J. Chem. Soc.* 115, 94-104(1919).—After reviewing Home Office Rept., Jan., 1915, on "Battery bell signalling systems" by R. V. Wheeler (cf. *C. A.* 9, 2190) and H. O. Rept., June, 1916, on "Electric signalling with bare wires," by R. V. Wheeler and W. M. Thornton, in which the ignition of explosive gases by sparks produced in signal bell circuits were studied, M. investigated low-tension sparks using air-core, open iron-core and closed iron-core cells with six different numbers of layers each, making measurements on the circuits after interruption. It is concluded that over the wide range of different conditions examined the igniting sparks all liberated the same amt. of energy. Regarding single spark ignition of explosive gases, initially at atm. temp. and pressure, the main results established are: (1) With a low-tension spark, the least spark energy required to ignite a given gas mixt. diminishes with increase of the voltage impressed on the spark circuit prior to the production of the spark. (2) When the circuit voltage is const., the spark energy required for ignition of a given gas mixt. by a low-tension spark is const. (3) With a high-tension spark (which consists of a capacity component preceding an inductance component), the incendivity of the spark (or ability to cause ignition) can be increased by increasing the proportion of energy in the initial part of the spark without increasing the total energy of the spark. (4) The incendivity of a condenser or capacity spark is greater than that of an inductance spark dissipating the same amt. of energy. (5) With a capacity spark, the least energy required for ignition of a given gas mixt. diminishes as the spark voltage increases. It is generally supposed that the energy required to produce ignition of a given inflammable gas mixt. is const. with similar physical conditions. If correct, then the fact that the total energy of the least igniting spark is found experimentally to vary with the conditions under which the spark is produced suggests that not all of the spark energy is utilized in the process of ignition, but only a portion at the commencement of the spark. It is possible that the inflammability of a gas as detd. by the least energy required to produce ignition is not const. for identical physical conditions of the gas, but it would appear to be useless to attempt an investigation of this by spark measurement. It is important to note that a spark is a varying source of heat which very rapidly reaches its max. intensity and then less rapidly disappears. Expts. prove that increase of the initial intensity of the spark results in increased incendivity. This indicates that ignition is due only to the initial part of the spark, and that in every spark there is a certain amt.

of unused energy which makes no contribution to the process of ignition. The proportion of unused energy must diminish as the initial intensity increases, but at present any measurements of the effective portion of the spark appear to be impossible. It follows from this that any attempts to specify the inflammability of a gas in terms of the total energy of the least igniting spark must necessarily yield the diverse results which have hitherto been obtained.

CHARLES E. MUNROE.

**Ammoniacal silver oxide solutions.** ALFRED TINGLE. *J. Ind. Eng. Chem.* 11, 379(1919).—A warning suggested by experience as to the dangerous explosive nature of such solns. due to the unexpected ready formation of  $\text{Ag}_3\text{N}$  even in absence of air.

E. J. C.

Standard alkali for mixed-acid control (HEARSEY, JOYCE) 7. Industrial value of the material of the national powder mills (ANON.) 18.

**Explosive.** K. V. NIELSEN and J. P. LARSEN. U. S. 1,293,882, Feb. 11. An explosive is formed of  $\text{NH}_4\text{NO}_3$  78.125, S 8.75,  $\text{KNO}_3$  7.5, glycerol 2.5, sago flour 1.25,  $\text{MnO}_2$  1.25 and resin 0.635 parts. This mixt. is stated to be insensitive to shocks and is exploded by a fulminate cap.

**Explosive.** A. J. MARIN. U. S. 1,293,154, Feb. 4. A "safety" explosive detonating freely in the open air with a No. 6 detonator is formed by mixing  $\text{NH}_4\text{ClO}_4$  44-47,  $\text{NaNO}_3$  32-34, a nitrohydrocarbon such as dinitrobenzene or TNT 29-34, and  $\text{H}_2\text{O}$  2-5 parts and compressing the mixt. so as to give it a density of a 1.25-1.6 after drying. Cf. C. A. 12, 226.

**Black gunpowder.** J. BUXBAUM. U. S. 1,293,326, Feb. 4. Black gunpowder is mixed with sufficient spirits of camphor to form a plastic mass and the mass is then dried. This treatment is stated to improve the properties of the powder for use in guns.

**Preventing explosions of guncotton in centrifugal driers.** F. D. CRANE. U. S. 1,295,089, Feb. 18. Premature explosion of wet guncotton in centrifugal driers is prevented by suddenly reducing the pressure within the receptacle surrounding the centrifugal wringer when the moisture content of the guncotton has been somewhat reduced by centrifuging. This sudden reduction of pressure causes rapid vaporization of the liquid remaining in the guncotton and thus serves to cool it and loosen up the mass.

**Recovering solvent from smokeless powder.** F. I. DU PONT. U. S. 1,294,066, Feb. 11. Solvents such as alc. and ether are recovered from smokeless powder or similar materials by gradually vaporizing the solvent and cooling this portion sufficiently to effect its condensation and returning (to the material undergoing drying) the uncooled and uncondensed solvent vapor. This method of drying smokeless powder serves to avoid waste of heat and cooling power.

**Priming composition for detonators.** C. J. S. LUNDGAARD. Dan. 23,470, Sept. 2, 1918. A priming compn. is composed of a mixt. of  $\text{Ca}(\text{ClO}_3)_2$ ,  $\text{Sb}_2\text{S}_3$ , and powdered glass, with the addition of red P and a binder such as shellac, resin, or rubber soln.

## 25. DYES AND TEXTILE CHEMISTRY.

L. A. OLNEY.

The post-war world-markets for American dyes. ALFRED T. MARKS. *Textile Colorist* 41, 68-70(1919).

E. J. C.

Practical observations on the determination of indigo. W. DEINISCH. *Färber-Ztg.* 29, 183-4, 194-7(1918); *J. Soc. Chem. Ind.* 37, 648-9A.—Titration with  $\text{KMnO}_4$ .

is the best technical method for detn. of indigotin. Since the results vary with the diln. at which the titration is made, the oxidation cannot be expressed by a single equation. The titration can, however, be standardized by employing a pure sample of indigotin. Const. values are obtained for any diln. exceeding 1 part to 18,000 of  $H_2O$ . H. recommends a standard diln. of 1 to 25,000 of  $H_2O$ . It has always been considered that 1 mol. of indigotin takes up 2 atoms of O, forming isatin, but H. shows that the reaction is complete with 90.0% of this proportion of O. It is therefore possible to get accurate results by using a  $KMnO_4$  soln., prepd. and standardized by the usual methods:  $(FeSO_4 \cdot (NH_4)_2SO_4 \cdot 6H_2O, KH_2(C_2O_4)_2 \cdot 2H_2O$  or  $H_2C_2O_4 \cdot 2H_2O)$ . The procedure is as follows: 0.3–0.5 g. of the finely powdered sample is warmed at  $70-80^\circ$  with 10 cc. concd.  $H_2SO_4$ , using 50 g. of garnets. After heating for 0.5 hr., the soln. is made up to 500 cc. Into each of 2 beakers, 25 cc. of the soln. are measured, and each is further dild. with 300 cc. of  $H_2O$ . Titration with  $KMnO_4$  (1 cc. = 0.539 g.  $Fe(NH_4)_2(SO_4)_2 \cdot 6H_2O$  = 1 g. indigotin) is carried out with each until only a faintly green color is perceptible. Then to one (A) is added 0.1 cc. of  $KMnO_4$ , so that when compared with the other (B), against a white ground, it has the paler green color. To (B) is then added 0.2 cc.  $KMnO_4$  soln., so that it shows the paler color. Then after bringing (A) to the same color (2 drops  $KMnO_4$  soln.), 1 drop more in either beaker will completely discharge the color of the indigotin. This method is the only satisfactory one for obtaining a definite end point in the presence of the reddish color of most samples of natural indigo.

W. F. FARAGHER.

**Determination of sulfur which produces sulfuric acid in sulfur dyeings.** W. ZANKER AND K. SCHNABEL. *Färber-Ztg.* 29, 26–9 (1918); *J. Soc. Chem. Ind.* 37, 685A. —S dyes when moist become acid in the air,  $H_2SO_4$  being formed. Presence of alkalies and increased temps. favor the oxidation. Various dyes were tested as purchased and after purification by dissolving 1 g. of dye and 2 g.  $Na_2S$  in 250 cc. of water, boiling for a short time, pouring into 3 l. of  $H_2O$ , acidified with AcOH, allowing to settle, washing 6 times by decantation with  $H_2O$  acidulated with AcOH, collecting the dye on hardened filter paper and drying at  $100^\circ$ . To est. the acid, the dye was mixed with 50 cc. 0.1 N NaOH, evapd. to dryness, and heated for 1 hr. at  $110-125^\circ$ . The labile S was thus converted into  $H_2SO_4$ , the wt. of which was ascertained by titrating back with standard acid, using phenolphthalein or litmus upon writing paper as the indicator. Results are tabulated for various dyes.

W. F. FARAGHER.

**Explanation of the printing of colored reserves on some vat dyestuffs.** R. HALLER. *Färber-Ztg.* 29, 1–3 (1918); *J. Soc. Chem. Ind.* 37, 688A. —In Haller's process for printing colored reserves (*C. A.* 12, 2445), Pomeranz considers that the indanthrene vat does not penetrate the printed vat dye, because the NaOH necessary to fix the indanthrene dye from the vat is not available, having reacted with the Zn and Mn reserve salts, thereby forming hydroxides of the metals (*C. A.* 12, 2446). H. maintains that the hydroxides of Zn and Mn are in the colloidal condition in the printed thickener and form a membrane which prevents the penetration of the indanthrene, which also is in the colloidal form. The NaOH, however, can penetrate the membrane and enable the reducing agent to reduce and fix the printed dye. The results of a process used at the Felmayer works, in which blue and red reserve effects are obtained by printing with  $MnCl_2$ ,  $Na_2Cr_2O_7$ , gelatin, etc., are held by H. to support his view.  $MnO_2$  produced on the fiber, in presence and absence of glue, shows entirely different forms, especially when the fiber is treated with cuproammonium soln. In the former case, a continuous membrane with uniform particles of  $MnO_2$  is formed, while in the latter case the fiber swells and then dissolves, leaving the  $MnO_2$  in comparatively coarse form. All thickening agents must act as "filters," thereby preventing the colloidal vat dye from reaching the fiber.

W. F. FARAGHER.

**Printed reserves with vat dyestuffs.** H. POMERANZ. *Färber-Ztg.* 29, 51-4; *J. Soc. Chem. Ind.* 37, 688A.—The stripping of indigo from a fabric by reduction and soln. in NaOH is unsuccessful because of the oxidation of the indigo white. This difficulty is obviated by converting the indigo white into an alkali-sol. compd. which is stable in air. ZnO and a quaternary ammonium base (Leukotrop W., B. A. S. F.) effect this change, making the process commercial. This same reaction makes possible the printing of bright indanthrene effects upon an indigo ground. Oxidation reserves either convert indigo white into insol. lakes, which are not fixed by the fiber, or prevent the vatted dye from fixation without intermediate oxidation. Cu salts, both sol. and insol., are good oxidizing reserves. With paranitraniline red, Cu salts are not permissible, but sparingly sol. salts of *m*-nitrobenzenesulfonic acid are suitable. These salts cannot be used with alk. prints, as sol. alkali salts are formed. Chlorides of Al, NH<sub>4</sub>, and Mn with a variety of filling agents, such as clay, PbSO<sub>4</sub>, etc., are used for indanthrene vats. The use of a reducing agent and the above salts with a vat dye gives a vat reserve for colored effects on vat grounds. In discussing Haller's views (cf. preceding abstr.), P. points out the possibility that the unreduced easily vatted dye may act as an oxidizing agent on the more difficultly vatted dye, thereby acting itself as a reserve.

W. F. FARAGHER.

**An investigation on the relative affinity for cotton and mordanting value of the tannins of galls, sumac, myrobalans, divi-divi, and quebracho.** ROY H. WISDOM. *J. Am. Leather Chem. Assoc.* 14, 6-9(1919).—W. analyzed samples of gall, sumac, myrobalan, and quebracho exts. and divi-divi in the raw material by the A. L. C. A. Official method. Solns. were prepd. containing 0.4 g. tannin per 100 cc. and pure cotton cloth was treated with these solns. to det. their affinity for cotton. The results are given in percentages of matter absorbed by cotton. Solns. were then made containing 0.5 g. of total solids per 100 cc. from each of the above materials and cotton cloth was treated with these as before. The % of matter absorbed by cotton based on the total solids was galls 21.3%, sumac 17.2%, myrobalans 16.6%, divi-divi 16.0%, and quebracho 19.7%. The mordanting values were obtained by washing the cotton treated in the above expts. and then passing it through an iron bath, after which it was ashed and the iron detd. This gives what was called the combining value. The relative mordanting value was then obtained by multiplying the combining value by the absorption value. On the total-solid basis the mordanting value was as follows: galls 135, sumac 118, myrobalans 98, divi-divi 80, and quebracho 66. In general, pure exts. should give the following mordanting values expressed in percentages using galls as a basis: galls 100%, sumac 87.4%, myrobalans 72.6%, divi-divi 59.2%. Since quebracho is an iron-green tannin it is not really comparable with the others as a mordant.

**Stains and discolorations on cotton piece goods.** O. H. FORSDALE. *Color Trade J.* 4, 77-8(1919).—Stains most likely to occur during the bleaching process are caused by lime, soda ash, Fe, Pb, Cu, oxy-cellulose, pseudo-mauveine, oil and bacterial action. These are discussed.

L. A. OLNEY.

**"Mulberry flax" in Italy.** A. SANSONE. *Boll. assoc. ind. laniera ital.* 32, 52-4 (1918); *Bull. Agr. Intelligence* 9, 1108-9.—About 50 yrs. ago a strong, resistant paper was made for a short time in Bergamo, using mulberry fiber. The author describes (in the original) his full scale expts., showing that the most practical methods for sepg.

the fiber in the mulberry branches (loppings) was as follows: Soak the branches in pools or ditches (not necessary if wood is green); crush the retted or green branches with a heavy roller on a cement, wood, or tiled floor; collect the bark thus sepd.; crush the wet bark mechanically to sep. the epidermis, which is easily powdered; screen to remove impurities; bleach with alkalis and acids, and then with a hypochlorite soln. These expts. were made with the idea of using mulberry fiber as a cheaper substitute for jute for making sacking. Mulberry fiber, de-gummed and bleached, can give products of much greater value than jute. Pasqualis made pure textiles of "mulberry flax." The author advises that it should be treated to obtain more even fibers, although they are shorter, then carded; the longest fibers should be mixed with cotton, spinning wool, or hat felt while the shortest should be used as a  $H_2O$ -absorbent. "Mulberry flax" alone or mixed with wool or cotton dyes perfectly. Two-shade effects can be obtained in the mixed tissues by means of the acid dyes used for wool. The short fiber can be used in paper making to strengthen paper made with inferior material. The yield of bleached fiber is from 10 to 20% of the dry bark, i. e., 2 to 5% of the wt. of branches treated. To obtain the best results the mulberry should be grown with a low trunk.

F. W. SMITHER.

**Manufacture of waterproofed canvas.** E. R. CLARK. *India Rubber J.* 56, 175-6 (1918).—Waterproofed canvas for military purposes must possess the following characteristics: maintenance of waterproof qualities in spite of service conditions, resistance to mildew, and suitability of color. Five methods are mentioned: (1) Al soap; (2) asphaltum, paraffin, pitch, etc.; (3) duplex fabric; (4) cuprammonium and processes based on dissolved cellulose; (5) drying oils. No. 2 seems to be the best method when asphaltum is used; resin is an undesirable addition to the mixt.; wool grease and rubber mixed in paraffin have value. The faults of the others are: (1) admits  $H_2O$  under severe conditions; (2) duplex cloth is subject to decompn., and the adhesive is often poor; (3) too expensive and fabric becomes harsh and gives off irritant dust; (4) generally inferior and fabric has a tendency to spontaneous combustion. Methods of inspection comprize: examn. for pin holes, general characteristics, etc.; permeability to  $H_2O$  by use of accelerated tests of actual conditions; resistance to mildew propagation; effects of extremes of climate; and chem. analysis for detection of deleterious ingredients.

FRANCIS MCGOVERN.

**Waterproofing fabrics.** E. JENTZSCH. *Färber-Ztg.* 29, 3(1918); *J. Soc. Chem. Ind.* 37, 688A.—To waterproof loosely woven fabrics so that water will not drop through but may penetrate slowly, J. finds that basic acetate or formate of Al is most suitable, prior to wax-proofing.

W. F. FARAGHER.

**Degumming of silk without soap.** E. RISTENPART. *Färber-Ztg.* 29, 181-2(1918); *J. Soc. Chem. Ind.* 37, 649-50A.—By the process of Buschhüter and Voigt (Ger. pat. 291,159), silk is degummed by satg. it with a soln. of an alkali salt of an acid (other than a fatty acid) which is weaker than the amino acids of the sericin, followed by steaming. The sericin is sepd. from the fibers and is removed by a soap bath or by the foam from a boiling soap bath. Silicates, borates, carbonates, stannates, sulfides or aluminates are suitable, as are the salts of the acids of acaroid resin. The addition of 0.5 g. "monopol" soap per liter is advantageous, and after steaming, especially in the case of yellow silks, the material is rinsed in cold  $H_2O$  and preferably washed in a hot soap bath to remove the products from the gum and the coloring matter. The soap bath may be used repeatedly and eventually used for dyeing baths. The degumming action depends on the proportion of salt, e. g.,  $Na_2CO_3$ , to silk, and also on the concn. of the salt. For any given concn. of carbonate, a certain minimum wt. of carbonate must be present to effect complete degumming and an excess has no useful purpose. With decreasing concns. of  $Na_2CO_3$ , the minimum quantity required also decreases.

Thus, for a 1.0% soln., the minimum wt. of  $\text{Na}_2\text{CO}_3$  lies between 1.64 and 2.35% of the wt. of the silk; while for a 0.5% soln. the minimum is 0.85–1.63%, and for a 0.2% soln., 0.54–1.0%. Centrifuges are used, and the quantity of soda depends upon the wt. of soln. left in the silk. If the wt. of soln. remaining is twice that of the silk, the concn. must be 1.0%; if 2.5 times, the concn. must be 0.5%; and if 3 times, the appropriate concn. is 0.2%. The variations are explained by the increased hydrolysis of  $\text{Na}_2\text{CO}_3$  with decreasing concn. Since only the required wt. is used, there is no danger of attacking the fibroin.

W. F. FARAGHER.

The formation of the thread in the spinning of artificial silk. H. OST. *Z. angew. Chem.* 31, I, 141–4 (1918); *J. Soc. Chem. Ind.* 37, 542A (1918).—A comprehensive discussion is given of the effects of form of jets, pressure upon the solns., rate of drawing the threads, and concn. and form of hardening baths, upon the size and character of the threads. Viscosity tests for satisfactory solns., methods of making  $\text{Cu.NH}_4$  cellulose solns., and compn. of some hardening baths are included.

Indoxyl. E. A. BOURCART. U. S. 1,293,680, Feb. 11. The pat. relates to a method for transforming arylglycinates or their derivs. into indoxyl without the formation of undesirable by-products. A mixt. of KOH 70 and NaOH 30 with  $\text{NaNH}_2$  30 parts is introduced into an autoclave fitted with a stirrer, while the mixt. is in dehydrated and heated condition and the pressure in the autoclave is raised to about 6–10 atm. by use of  $\text{NH}_3$  or aniline vapors. When the temp. has fallen to  $180^\circ$ , 50 parts of K phenylglycinate is introduced as quickly as possible while the temp. is prevented from rising above  $190^\circ$ . The reaction is immediate and as soon as the evolution of  $\text{NH}_3$  has ceased the melt is dissolved in ice-water and indigo is pptd. by usual methods.

Apparatus for dyeing yarn. M. NAGLE. U. S. 1,293,514, Feb. 4.

Purifying cottonseed-hull fiber. F. W. STOCKTON. U. S. 1,295,078, Feb. 18. Fiber sepd. from cottonseed hulls is purified by boiling in a 4% aq. soln. of caustic alkali for about 5 hrs. to soften the hull particles, mashing and disintegrating the latter by passing the material between rolls, and then subjecting the mashed mixt. to a cleaning operation to sep. the fiber from the disintegrated hull material.

## 26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN.

Iron protection by paint. J. N. FRIEND. *Iron and Steel Inst. Carnegie Schol. Mem.* 9, 77–123 (1918); *Sci. Abstracts* 22B, 10–11 (1919); cf. *C. A.* 7, 3590.—F. exposed plates of open-hearth, cold-rolled and annealed steel plates, 1 by 2 feet, 0.03 inch thick.

for 5 to 30 months. The plates were used as received from the mill, sand-blasted, and pickled in  $H_2SO_4$ . The paints consisted of pigments in raw and boiled linseed oils. Expts. on the oils showed that the oil films without pigment increased a max. of 18% in wt. and 3.3% in vol. in about 27 days, and then began decreasing in wt. and vol. The vol. and viscosity changes cause the coat to crinkle at first, and then to crack. Polymerization of the oil took place at  $200^\circ$  and above. The permeability of the films was detd. by impregnating filter paper and allowing it to dry, and then tying it over the mouth of a bottle containing  $CaCl_2$  and noting the gain in wt. of the bottle when placed in a damp atm. Permeability decreases as polymerization increases. Pigments diminish permeability and expansion of the oil film and make it stronger and more viscous. The amt. of pigment should be as high as compatible with good body and working properties of the paint. Within limits, the protection afforded by the paint film, increases with the thickness, but two thin coats are better than one thick coat of equal wt. (cf. *C. A.* 6, 1071). From expts. with paints on colored glasses and with colored pigments on wood and steel, F. concluded that red paints protect better than white, green or black paints. Iron structures should be painted with mill scale intact after scraping off loosely adhering flakes and rust; sand blasted and pickled iron that has been subsequently painted does not resist corrosion as well. Careful removal of rust before painting does not seem necessary, but the evidence is not conclusive. Accelerated lab. tests are misleading.

F. A. WERTZ.

**Prussian blue.** HERMAN C. FUCHS. *Color Trade J.* 4, 92-3(1919).—The manuf. of Prussian blue is only profitable when carried out on a large scale. It is formed by direct pptn. of  $K_4Fe(CN)_6$  with a ferric salt, but in practice it is obtained by pptn. with a ferrous salt followed by oxidation with any suitable oxidizing agent. The following are chiefly used: (1)  $H_2SO_4$  and  $HNO_3$ ; (2) bleaching powder and  $HCl$ ; (3)  $K_2Cr_2O_7$  and  $H_2SO_4$ ; (4)  $KClO_3$  and  $HCl$ . Methods of procedure with each of the oxidation processes is described. Important considerations are the extremely fine state of division necessary for the different ppts. and long time required for settling of ppt. during washing process (ten days). Filtering and pressing of washed color is also a protracted and troublesome operation.

L. A. OLNEY.

**Ship bottom paints.** A. HUTIN. *Rev. chim. ind.* 27, 233-4(1918).—A brief review of the function and use of antifouling paints. H. gives analyses of 3 such paints and discusses the requirements of the French Marine Bureau. The following compds. are reported in the samples tested:  $Cu_2(AsO_4)_2$ ;  $(CuOAs_2O_4)_2 \cdot (AcO)_2Cu$ ,  $CuCNS$ , and  $HgCNS$ . The following formula has given good results: Pb arsenate, 1 kg.;  $CuHASO_4$ , 1 kg.; ocher, 8 kg.; white spirit (heavy), 5 kg.; rosin, 5 kg.; turpentine, 5 kg.; tar oil (with its light products), 3 kg.; bakelite A, 2 kg.

F. W. SMITHER.

**Hardness and viscosity of varnishes.** R. P. L. BRITTON. *Oil and Color Chem. Assoc.*, Sept. 17, 1918; *J. Soc. Chem. Ind.* 37, 594-5A(1918).—The practical varnish maker's "thumb nail test" for hardness of a film is inadequate, and the mechanical testers of Laurie and Baly, Jahns, and Clemens measure toughness rather than hardness. B. describes a method to det. true hardness by scratching the film with various crystals, similar to the method used for detg. mineralogical hardness. A method using gelatin points of varying  $H_2O$  content was also suggested. For viscosity detns., instruments which measure force as against time are recommended. B. has developed a viscosimeter which det. the time taken for a glass or metal ball suspended on one arm of a balance of high moment of inertia, to fall a definite distance through the liquid. The time required under similar conditions in air and in  $H_2O$  are used to standardize the instrument, and the viscosity is calcd. as the time taken in the liquid less time taken in air, divided by retardation for  $H_2O$ . As equilibrium is readjusted after im-

mersion of the ball, a correction is made for sp. gr. Some results are: linseed oil 7.7, olive oil 10.5, rape oil 12.1, castor oil 200. F. A. WERTZ.

**Pigments for printing inks.** T. M. TYSON. *Oil and Color Chem. Assoc.*, Nov. 1918, 1, No. 5; *J. Soc. Chem. Ind.* 37, 742A(1918).—Printing inks may be divided into two classes, "lithjo" and "letterpress." The pigments for the former must be completely free from acid, quite insol. in  $H_2O$ , possess good "solidity," moderate transparency, and not too high a sp. gr. Those for letter press inks must be brilliant and opaque and when used in process or three-color work, must have low sp. gr. The pigments are preferably composed of dyes fixed on alumina either alone or co-pptd. with blanc fixé, the lake and mineral pigments being pptd. simultaneously. Barytes or other abrasive material is quite useless as a base for either class of work. The desirable qualities of a good printing ink pigment are principally brightness and strength, the latter property ensuring that sufficient printed impression will be obtained by the use of a very thin film, thus guarding against liability to "set off" on the superposed sheet. Other properties are required for special purposes, *e. g.*, transparency and resistance to heat for tin printing pigments; insoly. in EtOH for labels which are subsequently spirit varnished; resistance to alkali for use on soap wrappers. A classification into degrees of fastness to light and the adaptation to different purposes of pigments of varying stability to light, alkali, etc., is given. F. A. WERTZ.

#### African oil-yielding plants (PIERARETS) 27.

**Manufacture and use of japan.** W. P. DAVEY. U. S. 1,294,627, Feb. 18. Articles to be coated with japan are immersed in an emulsion which may be prepd. from asphalt, fish oil, or China wood oil, copal, Mn resinate and  $NH_4OH$ , an elec. current is passed through the bath, using the article to be coated as anode, and the coated article is then baked.

**Non-inflammable japan.** W. P. DAVEY. U. S. 1,294,422, Feb. 18. A japan adapted to be dried and hardened by heating and not readily combustible is formed of an emulsion of asphalt, a saponifiable oil such as China wood oil, copal, Mn resinate,  $NH_4$ , and  $H_2O$ .

**Oxidation product of coumarin and indene.** K. SCHLATTER. U. S. 1,294,836, Feb. 18. A material suitable for use as a varnish is produced by the action of chromyl chloride upon compds. of the coumarin and indene groups in the presence of a volatile solvent, a gum and an oil, *e. g.*, a mixt. formed of Chinese wood oil or linseed oil, coumarin, dammar gum and  $CCl_4$ .

## 27. FATS, FATTY OILS AND SOAPS.

---

### A. SCHERUBEL.

**Oil of Pistacia lentiscus.** *The Cyprus Agr. J.* 13, 28-9(1918); *Bull. Agr. Intelligence* 9, 1106.—In Cyprus an edible oil (shinia oil) is extd. from the fruit of *Pistacia lentiscus*, a plant which grows wild throughout the island. Although the consumption of this oil has increased greatly of latter years its prepn. only constitutes a small industry of the poor classes, who manuf. it for domestic use, and but little for commerce. The yield is about 18%. Owing to the primitive methods of prepn. it rarely keeps more than 3 months without turning rancid. R. H.

**The oil content of coconuts on heavy clay soil.** J. B. HARRISON AND C. B. W. ANDERSON. *Rept. Dept. Sci. & Agr. Brit. Guiana* 1916, 43-4; *Exptl. Sta. Rec.* 39, 544.—Analyses of coconuts growing on heavy clay soil in the exptl. fields of the de-

partment of Science and Agriculture are reported. The data given show that the oil content of the nuts compares favorably with the oil content of coconuts grown in various other countries.

E. J. C.

Experiments on the biological saponification of various fats from the French colonies. F. HEDM. *Bull. de l'office colonial* 11, 227-34(1918); *Bull. Agr. Intelligence* 9, 1106-7.—A study has been made of the fats capable of being split up and treated with castor-oil enzyme without having to be subjected to the different operations required for aq. acid or alk. sapon. The only fats on which castor-oil enzyme had any notable action under the exptl. conditions adopted, were oil of cotton, tea, the pericarp of aouara, the kernel of aouara, *Puntumia elastica*, *Carapa microcarpa*, *Sorindeia olessa*, and *Chrysophyllum congoense*. As a rule the proportion of acids formed is fairly low, and, with the exception of *Carapa microcarpa*, is rarely above the 80 or 90%, which has sometimes been found in sapon. with castor oil. This may be due to the relatively high temp. at which the fermentation tests were carried out, 37° to 38°, the optimum temp. being about 30°. This higher temp. was indispensable to maintain the fat in the liquid condition essential to the normal progress of fermentation. The initial acidity of the oils of the pericarp of aouara and *Chrysophyllum congoense* indicates that they contain a saponifying enzyme.

F. W. SMITHER.

"Sélé," "cocorico," and *Ximenia americana*, African oil-yielding plants. J. PIERAERTS. *Annales du Musée Colonial de Marseille* 25, [4] 1-21(1917); *Bull. Agr. Intelligence* 9, 1060-1(1918).—Of the 3 seeds examd., the first 2 came from the Belgian Congo and the third from British Africa. Sélé. P. examined a specimen from Mowbasa (Bengala district) prepd. locally by: (1) roasting the seed, decortication and winnowing; (2) disintegration of the kernel by pounding; (3) sepn. of the oil by boiling H<sub>2</sub>O; (4) removal of the supernatant oil and clarification by standing and filtration. The oil consists essentially of a mixt. of glycerides of oleic, linoleic, stearic, palmitic, and lauric acids. It also contains a small amt. of an unidentified acid of a higher mol. wt. Sélé oil is an excellent edible oil with good keeping qualities and is suitable for soap-making. It is useless for the manuf. of stearin products. It may be considered as a semi-drying oil to be classed with cottonseed oil. Cocorico. This plant is a variety of *Citrullus vulgaris*. The oil examd. was prepd. in April 1914, by a method similar to that used for sélé, except that decortication precedes roasting. The oil has all the desirable qualities of sélé oil. Cocorico seed contains 37.5% of oil which, in ratio to the kernel, is 50.45% of the dry matter content. The cake is rich in N and would make an excellent fertilizer. The tegument of cocorico seeds contains an appreciable amt. of N and would make excellent composts. The low unit yield and the difficult and slow decortication of its seed make cocorico useless for com. (export) purposes. *Ximenia americana*. This bush belongs to the Oleaceae family. In S. Africa the plant is called "zuur pruijn" (acid plum). In all probability the plant will be largely used commercially and cultivated more carefully and intensively. Particular attention is drawn to the hexabromide test and the special properties of the solid acids. Based on the % of Br derivs. insol. in ether *Ximenia* should come immediately after linseed and candle-nut oil in the list of drying oils, with respect to the linoleic acid content.

F. W. SMITHER.

*Elaeis poissonnii*, a new species of oil palm, in the Cameroons. FAUCHÈRE. *Bull. de l'office colonial* 11, 80-3(1918); *Bull. Agr. Intelligence* 9, 1061-2.—The species is remarkable for its fruit which is enclosed in a sort of fleshy sheath formed by the development of 6 staminodes contained in the female flower which, in the other varieties of *Elaeis* hitherto described, are always atrophied. The fruit weighs from 10 to 20 g. Annet distinguishes 2 varieties, tenera and dura. A comparison of these 2 varieties with each other and with the var. Lisombe of *Elaeis nigrescens* gave: Tenera, oily pulp 76%

(sheath, 37; pericarp, 39); nuts 24% (shell, 13; kernel, 11); oil yield of the pulp, 70.25%; of the whole fruit, 53.5%. Dura (same sequence), 44% (18; 26); 56% (42.6; 9.8); 58.6%; 55.8%. Lisombe, 61.5%; 38.5% (21.5; 17); 63.15%; 38.35%. The wts. in g. of the fruit, the pulp, kernel, and oil in 10 fruits are given for each of the chief varieties of *Elaeis* in the Cameroons (the 3 above and the var. Dibope). F. W. S.

**A study of the viscosity of various colonial oils.** F. HENM. *Bull. l'office colonial* 11, 251-64 (1918); *Bull. Agr. Intelligence* 9, 1367-8 (1918).—The viscosity of oils and fats varies with different physical properties. If oils are divided into 3 groups, drying, semi-drying, and non-drying, the viscosity increases considerably with the d. in each group. This also applies to fats. The viscosity of an oil does not appear to depend on the solidifying point and, except in the case of very viscous oils, it increases with the m. p. of the fatty acids. In the case of fats it increases with the m. p. of the fat or fatty acids. Viscosity also varies with the chem. compn. of the oil or fat and decreases as the oleic acid content increases. Viscosity varies with the I no. and, for liquid oils, is higher in proportion as this value is lower. F. W. SMITHER.

**Prospects for China's oil industry.** D. B. HOU. *Science (China)* 4, 321-5, 448-59 (1918).—H. discusses the specific properties of 19 vegetable oils produced in China, and indicates the industrial use for which each oil is best suited. Particular attention is drawn to the possibilities of tung oil (Chinese wood oil), and soy bean oil.

WM. H. ADOLPH.

**Note on the acidity of castor oil of Indo-Chinese manufacture.** ROSÉ. *Bull. econ. Indochine* 20, 643-8 (1917); *Expt. Sta. Rec.* 39, 504-5.—As the castor oil which is used as a lubricant for aviation motors must be abs. limpid and possess an acidity in oleic acid not exceeding 15 g. per l., investigations were conducted for the purpose of ascertaining the conditions under which such an oil could be prepd. Detns. of free acid in different samples of the oil showed that the acidity increases on standing unless the oil is heated to 95° for about 10 mins. This would indicate that increasing acidity is due to the action of enzymes in the oil which are destroyed by heat. If the heating of the oil is followed by immediate filtration, an oil of the necessary standard of limpidity and acidity is easily obtained. E. H.

**Contribution to the chemical study of the fruit of *Camelia drupifera*.** BOUVSIOR. *Bull. econ. Indochine* 21, 232-4 (1918); *Expt. Sta. Rec.* 39, 501.—Analytical constns. are given of the oil, press cake, and whole seed of *Camelia drupifera*. The oil obtained by pressing in the cold was limpid after filtration, very transparent, and of a golden yellow color and a sweet and agreeable taste and odor. Its chem. constns. were as follows: acid number in percentage of oleic acid 1.36, sapon. number 194.48, I number 82.82, Reichert-Meissl number 0.22, and unsaponifiable insol. fatty acids 93.79. The oil contd. no alkaloid or cyanogen compds., but traces of the glucoside saponin. B. considers that the oil would be suitable for soap making and, if the saponin were removed, would make an excellent table oil. The press cake could be used to advantage as a fertilizer, particularly as the saponin contd. in it is toxic for the larvae of insects.

ELLIS, CARLETON: *The Hydrogenation of Oils, Catalysts and Catalysis; and the Generation of Hydrogen and Oxygen.* 2nd Ed. Thoroughly revized and enlarged. New York: D. VAN NOSTRAND Co. 767 pp. \$7.50. Cf. C. A. 9, 389.

**Hydrogenating oils.** C. ELLIS. U. S. 1,294,068, Feb. 11. A current of H is passed through a shallow layer of fatty oil to be hydrogenated, containing finely divided catalytic material. The unabsorbed gas is collected and a portion of it is purified by passing it through NaOH or soda lime. The purified portion is then combined with the remaining unpurified portion and this mixt. is used for further hydrogenation in a cyclic manner.

**Preparing cottonseed for milling.** W. E. McCAW. U. S. 1,293,830, Feb. 11. Natural cottonseed is prepd. for milling by heating to about 75-80° for about 10-45 min. and then cooling to atm. temp.

**Apparatus for extracting grease and oils from garbage.** C. EDGERTON. U. S. 1,293,738, Feb. 11.

## 28. SUGAR, STARCH AND GUMS.

A. HUGH BRYAN.

**Practical laboratory apparatus—filtering rack for sugar solutions.** C. W. HINES. *Philippine Agr. Rev.* 10, 434-5(1917); *Expt. Sta. Rec.* 39, 505.—The filtering rack described by H. was devised to obviate the delay in obtaining a clear filtrate in the prepn. of sugar samples for polarimetric work. The app. consists of a double filtering rack, each compartment contg. a double row of holes. Beneath the back row of holes in both front and rear racks are placed small pans or troughs of galvanized Fe which receive the first filtrate which passes. After the clear liquid has begun to pass through, the funnels are moved to the front row of holes and placed above clean beakers to receive the filtrate for polarization. E. H.

**Juice clarification and decolorization with a new carbon.** S. S. PECK. *Intern. Sugar J.* 21, 72-4.—See Report of Committee on Sugar Manufacture and Utilization of By-products, Hawaiian Sugar Planters' Association, C. A. 13, 667.

F. W. ZERBAN.

**Feed regulation of sugar factory steam boilers.** JAS. HAMILL. *Intern. Sugar J.* 21, 60-2(1919).—At times of sudden demand on the boiler, if the level of the water falls, the usual feed regulator opens and chills the boiler with a sudden supply of water. Conversely, when the demand for steam decreases suddenly the feed is cut off and there is no way of storing the excess heat till the fires can be lowered. This is particularly important in sugar mills with their sudden and large fluctuations in steam demand. If a feed water regulator could be devised with a time lag it would be desirable; so that when a sudden demand for steam came it would not at once turn on the feed, and would not at once turn off the feed in case of a sudden decrease. W. L. BADGER.

**Hinged housing for cane mills.** E. A. JARECKIE. *Sugar* 20, 504(1918).—The cap of the mill is made hinged, and the end opposite the hinge is combined with the hydraulic jack so that the whole cap can rotate about the hinge. The idea is to avoid binding in the bearings of the top roll. No kingbolts are used. W. L. BADGER.

Steffens-house waste water and stream pollution (COULTER) 14.

## 29. LEATHER AND GLUE.

ALLEN ROGERS.

**Degree of tannage in different stages of process.** OSKAR RIETHOF. *J. Am. Leather Chem. Assoc.* 14, 20-2(1919).—The author gives results of expts. made on

samples cut along the backbone 24 in. from the root of the tail and representing 3 different tan yards. Analyses showed degree of tannage from the sixth layer 90.3; half of tannage completed in 27 days and half time 71 days, the figure for the degree of tannage was 71.3, or in other words, in half the time the leather was four-fifths tanned. The second yard-degree of tannage after 108 days was 84.8; stock half tanned in 24 days; in half-time the degree of tannage was 74.0; or in other words in half time stock was three-fourths tanned. Third yard-degree of tannage from fifth layer after 87 days, was 86.2; stock half tanned in 29 days; in half time the degree of tannage was 64.3, and the stock was three-fourths tanned. It would be impossible to give a fixed rule for the extent of the tannage in half time because this depends on many factors; but, as a rule for our standard sole and belting leather tannages, in half time the stock is between three-fourths and four-fifths tanned.

J. S. ROGERS.

The quinone tannage. II. W. MOELLER. *Collegium* 1918, 210-3, 241-7; *J. Soc. Leather Trades Chem.* 3, 28; cf. *C. A.* 13, 522.—Anthraquinone and its derivatives are similar to diketones in their properties and do not give the ordinary quinone reactions. This fact has been attributed to constitutional influences, since the conversion of an adjacent benzenoid nucleus into an ethenoid compd. stimulates the latest quinone properties in anthraquinone. Thus the quinone or non-quinone nature of the phlobaphenes can only be settled by detn. of their constitutional properties and not by their behavior in the ordinary quinone tests. The coloration of pelt by quinone is due to a chem. reaction between quinone and the decompn. products of collagen. Quinone and alloxan give similar colorations with pelt. Alloxan oxidizes  $\alpha$ -amino acids to aldehydes and it probably exercises a similar function with regard to hide decompn. products. It is unlikely that alloxan has any tanning properties. Only benzoquinone and toluquinone correspond to alloxan in their behavior towards  $\alpha$ -amino acids. Thus quinones are divided into 2 classes: (a) those which merely polymerize, forming colloidal complexes, and have a quite stable quinone character such as the phlobaphenes; and (b) those which oxidize  $\alpha$ -amino acids, forming colloidal complexes as a result. Quinones unstable in  $H_2O$  belong to the second class, such as the polyphenols of the vegetable tannin colloid peptiser which can change through all phases of the quinhydrone formation up to complex colloidal humins. Quinone does not give a red color to the interior of the fibrils of fresh pelt, but if putrefaction has started the red color develops immediately. In the formaldehyde tannage it was noticed that formaldehyde combines with the free amino acids to form methylene compds. and that pelt treated with an excess of formaldehyde does not give any coloration with quinone soln. These expts. show that the first step in quinone tannage is an oxidation process facilitated by the free amino acids present resulting in the formation of hydroquinone and then quinhydrone. The oxidation proceeds to the formation of colloidal humins. Unchanged quinone cannot be detected in finished quinone leather. How far the aldehydes formed from the  $\alpha$ -amino acids contribute to the quinone tannage is still undetermined.

R. W. FREY.

Elementary structure of the leather fiber. Principles of the molecular physics of leather. W. MOELLER. *Collegium* 1918, 157-73, 202-10, 230-40; *J. Soc. Leather Trades Chem.* 3, 28-9.—Hide tissue fibrils, although of ultramicroscopic size, are not homogeneous like ordinary cryst. structures. All organized matter consists of mixtures of chemically different substances, of which one is a solid cryst. compd. and the other surrounds these crystals like  $H_2O$ . Hide fibrils appear to be constituted with mixed crystals of collagen and its hydrolytic products. The collagen molecules form ultramicroscopic crystals called micells. From the complicated chem. structure of the protein mol. it must be inferred that the collagen micell is much larger than the micells of hydrolyzed collagen and that the collagen micell is permeable only to molecularly

dispersed compds. The collagen micell is probably polyhedric and elongated somewhat, and on swelling becomes spherical. The polyhedric form is retained to a certain degree and on drying the micells arrange themselves so that their ends will again be in contact. The optical axes of the micells will be disturbed in all directions but the micells are in chains and the general direction of these will not be altered. In gelatin the collagen micells have almost all disappeared and the hydrolytic products increased at their expense, thus producing a network. A broader conception of crystals now prevails and chem. homogeneity is no longer their essential property. Anisotropy in crystals is due to a kind of trellis-work structure and no real state of amorphy exists. Authorities are quoted to show that to a certain extent the properties of cryst. substances can be applied to amorphous substances. The adsorption phenomena shown by certain crystals lead to the conception that the structural elements of a hide fiber behave like a cryst. system with the inference that there is a trellis-work structure among the micells. Those substances which swell or dehydrate the micells or the micellar network cause pressure on the micellar structure with the result that the axial orientation is diverted from the longitudinal direction. All tannins have this property and the twisting of the micellar chains can be followed microscopically. There seems ground for assuming that the micells are not arranged in the same longitudinal plane but spirally. The wave-like appearances observed in gelatin jellies are a direct proof of the presence of a micellar framework in the fibrils, and that these are arranged in the form of layers of network. The anisotropy of the fibrils depends upon the fact that the micellar chains arrange themselves in lines parallel to their optical axes. The astringency of the tannin causes the micells to impinge on each other, hence anisotropy disappears. Tanning of micellar chains is only possible if they are under no stretch. In such a condition, in consequence of the action of the peptizer in the tanning soln. an alteration takes place in the arrangement of the micellar chains whereby the micellar interstices are enlarged and the peptized substance is brought into direct contact with the micellar chains. If hide is under tension, then the micellar chains are under tension and they are not penetrated by the tannin although the whole hide may appear tanned through.

R. W. FREY.

**The action of neutral chlorides on chromic chloride solutions.** MABEL E. BALDWIN. *J. Am. Leather Chem. Assoc.* 14, 10-9 (1919).—Solns. of  $\text{CrCl}_3$  containing increasing amts. of neutral chlorides were prepd. so as to give 13.77 g. per l. of  $\text{Cr}_2\text{O}_3$  and concns. of the neutral chlorides equal to 0, 1, 2, 3 and 4 *M* solns. The salts used were  $\text{KCl}$ ,  $\text{NH}_4\text{Cl}$ ,  $\text{NaCl}$ ,  $\text{LiCl}$  and  $\text{BaCl}_2$ . Electrometric measurements of the H-ion concn. were made immediately after prepn. and also 50 days later. These measurements show that the H-ion concn. is increased by the addition of neutral chlorides although the total amt. of acid H remains the same. The neutral salts differ in their ability to increase the H-ion concn. The order of this increase is as follows:  $\text{KCl} = \text{NH}_4\text{Cl}$ ,  $\text{NaCl}$ ,  $\text{LiCl}$ ,  $\text{BaCl}_2$ . A similar series of expts. was conducted, using a 0.1 *M* and a 0.004 *M*  $\text{HCl}$  soln. instead of the  $\text{CrCl}_3$  to det. if hydrolysis of the Cr salt was a factor in influencing the result. When the neutral chlorides are arranged in the order of their increasing degree of hydration at infinite diln. the following series is obtained:  $\text{KCl}$ ,  $\text{NH}_4\text{Cl}$ ,  $\text{NaCl}$ ,  $\text{LiCl}$ ,  $\text{BaCl}_2$ . The salt which unites with the greatest no. of mols. of water is the salt which is most effective in increasing the H-ion concn. and therefore in increasing the amt. of alkali necessary to start pptn. in a chrome liquor. Comparison of the results obtained in this acid series with those obtained in the  $\text{CrCl}_3$  series show that the neutral salt effect is not a result of the hydrolysis of the Cr salt, the H-ion concn. being effected in a similar manner by the neutral chloride in the acid series as in the  $\text{CrCl}_3$  series. In aq. soln. the mol. and ions of a salt combine with mols. of water. Since these hydrated particles, each one of which contains a comparatively large no. of mols. of water, func-

tion as a unit constituting the solute, a portion of water is removed from the solvent, and the amt. of water acting as solvent is thereby diminished. This has the effect of increasing the H-ion concn. Actual acidity as differentiated from total acid H, appears therefore to be due not to the concn. of H ions in mols. per l. of soln., but to a ratio between the no. of H ions and the no. of water mols. That the hydrate theory affords an explanation of the neutral salt effect is thus made much more vivid by electrometric measurements of H-ion concns. J. S. ROGERS.

**Note on Kjeldahl's method for the determination of nitrogen as applied to gelatin.** H. G. BENNETT AND N. L. HOLMES. *J. Soc. Leather Trades Chem.* 3, 24-7(1919).—Difficulty in obtaining concordant results for N in gelatin led to expts. for detg. the shortest reliable time and the best method for complete hydrolysis. Sheepskin gelatin, of especially good quality was digested with  $H_2SO_4$  for varying periods under the following conditions of acceleration: (1) with no accelerator; (2) with 2 g.  $Na_4P_2O_7$ ; (3) with 5 g.  $Na_4P_2O_7$ ; and (4) with 10 g.  $K_2SO_4$ . The data show that the clearing of the soln. during digestion is no sign of complete hydrolysis and that in all cases prolonged digestion gives low results through loss of  $NH_3$ . With  $H_2SO_4$  alone correct results cannot be obtained as very long digestion is necessary for complete hydrolysis and, although the % N increases up to about 12 hrs. digestion it afterwards decreases slowly, due to loss of  $NH_3$ . It is also shown that  $Na_4P_2O_7$  is not quite as efficient as  $K_2SO_4$ , and that 10 g. of the latter and 4 to 6 hrs. digestion give the most reliable results. The results for all expts. are presented in tabular and graphical form. R. W. FREY.

**Determination of the adhesiveness of glue.** M. RUDELOFF. *Mitt. kgl. Materialprüfungsamt.* 36, 2-49(1918); *J. Soc. Chem. Ind.* 37, 743A.—The soln. of the glue is applied to the planed end surfaces of 2 pieces of red beech wood 185 mm. long, 125 mm. broad, and 50 mm. thick, and these are placed so that the glued surfaces cross at right angles. The glue film is then allowed to dry under definite pressure, and the force required to tear the pieces of wood apart is measured by means of a suitable machine. In a series of detns. made in this way it was found that for glue solns. up to 200% of water (referred to wt. of glue dried at 100°) the tenacity of the film decreased in proportion to the extent to which the wood was heated prior to glueing, but that in the case of solns. with 300% of water the greater degree of heating had a favorable influence. The tenacity of the glue film does not decrease in direct proportion to the rise in the amt. of water. In the case of solns. with 100 to 150% of water the pressure under which the glue film is dried has no appreciable influence on the tenacity of the film, but with higher amts. of water the drying pressure has considerable influence, especially when the wood has been previously heated. The most suitable conditions for testing samples of glue by this method are the use of solns. contg. 150% of water, previous heating of the pieces of wood to 40° in dry air, and drying of the film under a pressure of not less than 0.84 kg. per sq. cm. Solns. contg. 100 to 150% of water give concordant results by this method, which may also be used for comparison with the results obtained by detg. the viscosity at 35° of glue solns. with 556% of water. E. J. C.

### 30. RUBBER AND ALLIED SUBSTANCES.

JOHN B. TUTTLE.

**The rubber industry—past and present.** B. D. PORRITT. *J. Roy. Soc. Arts* 67, 252-67; *India Rubber J.* 57, 411-5, 445-8(1919).—Historical review of the early uses of crude rubber, the discovery of the vulcanization process, and the subsequent development of the industry; particularly valuable for its early patent and literature references.

JOHN B. TUTTLE.

The factors which influence the latex flow from *Hevea brasiliensis*. W. H. ARISZ. *Arch. Rubbercultuur* 2, 347-60(1918).—The depression of f. p. (indicating the amt. of salts, quebrachite, sugars) produced by latex derived from a given tree under various conditions is studied. At 0.3 m. from the ground the latex obtained from a root cut gives a smaller depression than latex obtained from an ordinary cut. (Extreme figures were 0.642 and 0.830%.) When the latex from a given cut is collected in two parts, the part issuing last gives a smaller depression than that issuing first. The latex obtained at 3.5 m. gives a greater depression than that obtained at 0.3 m. When collected in two parts, the second part again shows a smaller depression than the first. It is concluded that the latex obtained from a cut during the later period of the flow probably has its origin in the lower parts of the tree—in the case of the ordinary cut, in the roots. In agreement with this view is the following observation: When a cut is divided into three sections, and the latex from each section is collected, in two parts, separately, the diminution in the depression produced by the second part as compared with the first is greater in the middle section than in the end sections. It is assumed that the second part from the middle section comes almost entirely from the roots, while that from the end sections comes partly from the layer just outside the ends.

G. S. WHITBY.

The preparation and vulcanization of plantation Para rubber. B. J. EATON, J. GRANTHAM AND F. W. F. DAY. Kuala Lumpur. *Agr. Bull. Federated Malay States* 17, 1-398(1918); cf. C. A. 10, 112, 400, 1113-5, 2539-40, 3000; 11, 222-3, 899, 1055, 2417, 2550; 12, 107, 439, 637, 1010, 1135-6, 2711.—In this bulletin the authors have united their previous publications on the subject of the variability of plantation Para rubber, adding further exptl. data in many instances. The conclusions from all this work may be summarized as follows: First-grade plantation Para rubber, either pale crepe or smoked sheet, is more variable than hard fine Para. This variability manifests itself in the rate of vulcanization and the tensile properties, and is caused by varying amts. of org. accelerating agents from two sources, (a) a decompn. product of the protein of the latex, (b) substances which exist in the latex, and are not removed under certain conditions of prepn. The first named is probably an amine or amino acid. By light pressing of the coagulum, and allowing it to mature for 6-7 days, the max. amts. of accelerators are formed, and are not removed later in creping. Smoking the rubber, formalin, boric acid, tannic acid, and certain antiseptics inhibit the formation of the accelerators and hence retard vulcanization. Sterilization by heat or refrigeration act in the same manner, although in these cases the reaction may take place after the influence of these factors is removed. Under certain conditions, the N content showed some relationship to the rate of cure, the lower the N the more rapid the rate of cure, but this did not apply universally, and hence cannot be used to det. the rate of cure. AcOH has been found to be the most satisfactory coagulating agent, but other org. acids can be used. Mineral acids are not satisfactory as they injure the rubber. Alum is objectionable, but NaHSO<sub>3</sub> is permissible for pale crepe. The poorer grades of plantation rubber are usually more uniform than the better grades, largely because they are more thoroughly mixed. In technical mixings, the use of PbO or org. accelerators, tends to obscure or entirely to overcome the variability in the rate of vulcanization of the raw rubber. The bulletin contains a bibliography on the subjects of variability and testing of rubber, and a detailed description of the rubber factory at Kuala Lumpur where these researches were made.

JOHN B. TUTTLE.

Differences in weight in the preparation of sheet and crepe rubber. O. DE VRIES AND H. J. HELLENDORF. *Arch. Rubbercultuur* 2, 361-400(1918); *Meded. Cent. Rubberstation* 8, 1-40.—An extended series of expts. ascertaining the differences in the wt. of the product from a fixed quantity of latex, which are brought about by a

considerable range of differences in the procedure. It is found that leaving the coagulum standing in the serum, soaking the coagulum in water, diluting the latex, all lead to a smaller wt. in the product. Sheet is always markedly heavier than crepe prepd. under the same conditions of diln., etc., The following are relative figures for a few of the conditions examd.; they include the conditions usual in practice. Crepe from latex is dild. to 15%, the coagulum being kept in the serum, and rolled the following day, 100; crepe from undild. latex, the coagulum being rolled a few hrs. after coagulation, 100.9; sheet from undild. latex, the coagulum being kept in the serum and rolled the next day, 101.4; sheet from latex dild. to 15%, the coagulum being kept in the serum and rolled the next day, 100.6. The moisture content of most of the samples was detd. It was higher, the greater the relative weight of the rubber, i. e., the larger the amount of serum solids included.

**Vulcanization tests.** VI. L. E. CAMPBELL. Dept. Agr. Ceylon, *Bull.* 35; cf. C. A. 12, 543.—Vulcanization expts. were carried out with rubber from latex of trees 16–20 years old. The samples were prepd. by adding creosote or formalin to the latex before coagulation with AcOH. The rubber was formed into sheets or blocks, part being dried at once and the remainder left wet. Moist rubber was found to vulcanize more rapidly than the dried samples from the same latex and appeared to have as good physical properties. It also contained more resins and less protein. Considerable differences in time of cure occur in plantation rubber prepared at different times of the year from the same trees by identical methods.

OSMAN J. WALKER.

**Some remarks on the aging of vulcanized rubber.** O. DE VRIES. *India Rubber J.* 57, 77–81 (1919).—On account of comment on a previous article, further expts. using accelerated aging tests, i. e., heating a vulcanized mixt. of 92.5 parts rubber and 7.5 parts S at temps. of 65–72°, after 70, 90 and 110 min. cures, for 24 hrs., enable the author to draw the following conclusions: (1) Stress-strain curve shifts its position in the same way as in ordinary vulcanization. The change during the first 24 hrs. is greater the shorter the time between curing and aging; change on further heating is practically the same for all states of cure with coeff. of vulcanization of 2.4%. Change on prolonged heating decreases, without coming to a stop before brittleness is reached as in overcure. (2) Tensile strength, though increasing as in prolonged vulcanization for a given stress-strain curve, does not reach the value obtained by ordinary vulcanization for samples with a coeff. of 2, 3 and 4%; the tensile strength on aging first shows an increase, but later the rubber becomes brittle. (3) Coeff. of vulcanization at temps. below 80° shows a small increase, so that the above mentioned physical changes which in ordinary vulcanization accompany the increase in combined sulfur, in aging are not a part of this chem. reaction. This last conclusion challenges the theory of Stevens (cf. C. A. 12, 2710) that coeff. of vulcanization is a safer guide for judging aging properties of rubber than the stress-strain curve. Alteration in vulcanized rubber after the first 24 hrs. of rest is so slight that it can be disregarded and reliable tests can be made after this period.

FRANCES MCGOVERN.

**Influence of certain chemicals on the inner qualities of rubber.** O. DE VRIES. *Arch. Rubbercultuur* 2, 67–104 (1918); *Meded. Centraal Rubberstation* 6, 1–38.—The effect on quality of each of the three anti-coagulants and two anti-oxidants most commonly used on rubber plantations is examd.  $\text{Na}_2\text{SO}_3$  has a small but distinctly favorable effect, producing, when added to the latex in the customary proportion of 1 g. per l. of 15% latex, improvements of 0.0–0.03 kg./mm<sup>2</sup>. in the breaking stress, 5–10 mins. in the rate of cure, 1–1.5 in the slope of the stress-strain curve, and 0.02–0.04 in the viscosity index.  $\text{CH}_3\text{O}$  has a prejudicial effect on the quality. If used in the usual proportion, 0.25–1 cc. formalin per l. 15% latex, the effect is small only, the figures

remaining well within the limits of ordinary variation of plantation rubber. But in larger quantities (which cannot always be avoided in practice) its effect is serious, 2-4 cc. affecting adversely the breaking stress by 0.0-0.08, the rate of cure by 5-15 mins., the slope by 0.5-1.5, and the viscosity index by 0.03-0.09. Formalin affects the quality, not only by its relation, as a disinfectant, to the biological processes in the unrolled coagulum, but also by acting directly, as it were, on the rubber. Formalin exerts an unfavorable effect when it is introduced into the rubber after the coagulum has been rolled, as when the coagulum is soaked in formalin, exposed to  $\text{CH}_2\text{O}$  vapor, or has paraformaldehyde added to it along with S on the mills. The third anticoagulant,  $\text{Na}_2\text{CO}_3$ , is intermediate between the other two. It has a slight improving effect.  $\text{NaHSO}_3$ , like formalin, acts in two ways, but here the ways are opposed, the direct effect being advantageous, while the effect in retarding the biological processes is prejudicial. Under ordinary conditions of working, the quality of the rubber is improved. The usual proportion of  $\text{NaHSO}_3$  (0.5-1 g. per l. latex) improves the breaking stress by 0.0-0.05, the time of cure by 5-10 mins., the slope by 1-1.5, and the viscosity index by 0.03-0.15.  $\text{Na}_2\text{S}_2\text{O}_5$  produces a very small improvement in the rate of cure and the viscosity. The effect was examd. of  $\text{AcONa}$  and of  $\text{H}_2\text{SO}_4$ , substances which will be formed when  $\text{AcOH}$  is added to latex containing  $\text{Na}_2\text{SO}_3$ ,  $\text{NaHSO}_3$ ,  $\text{Na}_2\text{CO}_3$ , or  $\text{Na}_2\text{S}_2\text{O}_5$ . The former produces a distinct increase in the rate of cure and the viscosity, but has no effect on the slope. The latter has no effect on the rate of cure, but produces a marked improvement in the slope (approx. 2 units) and a slight increase in breaking stress and viscosity.

G. S. WHITBY.

**Solid rubber tires.** ANDREW H. KING. *Chem. Met. Eng.* 20, 352-9(1919).—A popular, not absolutely accurate description of the methods used in the manuf. of carriage and motor truck solid tires and cushion tires.

JOHN B. TUTTLE.

**Destructive distillation of automobile tire beads.** A. DUBOSC. *Caoutchouc et gutta-percha* 15, 9617-9(1918).—For comparison of products obtained by destructive distn. of crude rubber with those of a vulcanized rubber product, D. subjects tire beads, after removal of all but the last layer of fabric, to distn. in an iron retort, provided with a thermometer, and connected with an ice-cooled condenser from which the products are passed into a measured vol. of  $\text{H}_2\text{O}$ . Active decompn. takes place between 75 and 145° and is complete at 245°. Products are as follows: residue 52% consisting of C 10.92% and ash 41.08%, composed of  $\text{ZnO}$ ,  $\text{PbO}$ ,  $\text{CaCO}_3$ ,  $\text{MgO}$ , and insol. matter; oil, 28.99%;  $\text{H}_2\text{O}$ , 8.33%; and gases (by difference), 10.68%. The condensed liquid contains  $\text{AcOH}$ ,  $\text{C}_4\text{H}_8$ ,  $\text{PhMe}$ ,  $\text{PhEt}$ , and dipentene, but no isoprene or heveene as in the case of crude rubber; the gases were  $\text{H}_2\text{S}$  and  $\text{C}_2\text{H}_4$ .

FRANCES MCGOVERN.

**Nature of mottling of vulcanized para rubber.** H. RIMPEL. *Gummi-Ztg.* 31, 144; *Chem. Ztg.* 42, 119; *J. Soc. Chem. Ind.* 37, 595A(1918).—The sample examd. was free from substitute and yielded only about 3% ash. The lightest colored patches contained about twice as much free S as the darkest. R. explains their formations as follows: After vulcanization the S which has not combined chemically with the rubber passes on cooling into the amorphous or rhombohedral form, except at the surface, where octahedral crystals quickly sep. S wanders from the interior to the surface, causing bloom. At the same time there occurs the conversion of the less stable into the more stable form within the sample, the rubber acting as a solvent, and the S wanders from certain parts of the soln. and collects at other centers. ELMER A. DANIELS.

**Manufacture of waterproofed canvas (CLARK) 25. Testing of sodium bisulfite (VAN HEURN) 7. The mutual condensation of unsaturated compounds in connection with terpenes, resins and rubber (PRINS) 10.**

**Rubber-like substance.** H. S. A. HOLT and G. STENNING. U. S. 1,294,662, Feb. 18. A substance similar to rubber and insol. in  $C_6H_6$  is obtained by polymerizing isoprene or other hydrocarbon of the butadiene series in the presence of about 3% of an org. ozonide (such as 2,3-dimethyl-1,3-butadiene ozonide or oxidized caoutchouc), which is capable of intimately mixing with the hydrocarbon. The polymerization is effected by heating for some time at 60-100°.

**Rubber substitute.** H. H. HAZELTINE. Can. 189,232, Mar. 25, 1919. A rubber-like substance comprizing a mixt. of fixed oil, S and ZnO free from air and moisture which has been subjected to heat, pressure and agitation until the nascent period of the elements reacting has ceased.

**Adhesive rubber composition.** E. M. SLOCUM. U. S. 1,293,957, Feb. 11. An adhesive mixt. adapted for coating tape is formed by mixing thickened castor oil, dissolved in a solvent such as gasoline, with a rubber-containing latex, and coagulating the mixt.

**Coating for handles of trade and sporting implements.** W. S. SELLARS and W. W. TAYLOR. U. S. 1,293,949, Feb. 11. A soln. of equal amounts of gutta percha and balata is used for coating handles of tools, golf clubs, ball bats or other articles to produce a slightly yielding grip which does not become sticky or tacky from the heat of the hand.
